ONION CULTURE (*A Gardener Perplexed*).—There are many different ways of securing a good crop of Onions, but the mode described by you of preparing the ground so carefully, sowing, covering, &c., leaves little or nothing to be desired or alluded to, and we need scarcely be strengthened in this conclusion by your statement that such a mode has secured good crops for seven years. We are not surprised that your employer on coming into the garden should say "he never saw Onions put in in such way before," as it is quite possible he had never troubled himself to notice the mode previously adopted; but it does surprise us that because the sowing "was not done properly," you are obliged to leave your place, and more especially when your employer declined to say what was the plan he approved. Of course, in this country a man may leave his master, and a master part with a servant without assigning any reason, though such conduct on either side does little to promote the amenities of life. We can hardly believe that a gentleman would assign such a reason as the sowing of an Onion bed under such circumstances. When you inquired the mode your employer preferred, was there no lack of that courtesy and consideration which every employer has a right to expect, however mistaken he may be in his ideas? We can just fancy there might be something more annoying in this direction than any differences of views as to the sowing of the Onion bed. If not, and your version is a true one, then we think you have been hardly dealt by, and being a married man with a family, we can only hope you will soon be more comfortably settled. We do not see how you could be blamed for following your own mode, if your employer expressed, and would express no opinion on the subject. Gardeners are a little touchy in not having their own way; but an old nurseryman once impressed on a young gardener that the wishes of an employer, when expressed, must be carried out, and ended with saying, "if a master wished a tree to be planted with branches in the ground, and the roots in the air, let it be done; he pays for the work, and should have his money spent in his own way if he injures no one else."

ROYAL ASCOT VINE (*A Monmouthshire Gardener*).—We do not think it is common to send out new Vines started into growth in February, but if you had no heat, you should have made sure of a Vine that was not started into growth. Of course, a nurseryman would send as little wood of a new Vine as he could. Every bud is valuable when a plant is worth two guineas. As your two buds are growing, and you have no frame, pit, or hand-light that you can keep warm, we would place the plant with its pot in your living-room window, and surround it with some squares of glass, or a large hand-glass. There are few gardeners that order a two-guinea Vine but would find some means of keeping it growing slowly, even in a coolinery, if a bell-glass or hand-light could be made available.

STAR PINKS.—"J. H." wishes to know where he could obtain a good assortment of Star Pinks.

ZEBRA RUNNER BEAN.—In answer to "LANSLOWNE, Worcester," if he will apply to Mr. S. Taylor, Gardener, Terrace Villa, Barbourne, Worcester, he obligingly offers to supply him with sufficient to regain his stock.

BRIDGEWATER TILES FOR COPIING.—In answer to "IRISH SUBSCRIBER'S" inquiry as to where the Bridgewater tiles are to be bought, I beg to say that if he writes to either Messrs. Sealy or Messrs. Brown, Bridgewater, Somerset, they will doubtless give him any information he may require. Any other good tile, if large enough, would do as well; the great point is for the roof to overlap the wall 10 or 11 inches. Trusting to memory, I find I made a mistake in the measurement of the overlap in my letter. It should have been 11, instead of 10 inches.—A SOMERSETSHIRE PARSON.

TORRACIO PAPER (*M. J. and S.*).—It is impossible, without analysing it to ascertain if there is any constituent in it likely to be prejudicial to plants when it is burnt. The probability is that the smoke was too abundant, and the plants not in a fit state to endure it.

YELLOW-LEAVED PLANE TREE (*G.*).—We cannot speak decidedly, but think that the tree you saw is the *Corsorphine* Plane, *Acer pseudo-platanus flavo-variegata*.

PROMISE OF CUCUMBER HOUSE (*A Constant Reader*).—It is very difficult to answer your questions, as so much depends on the management and the market; but we know of one such house in which 1500 fruits were produced in a season, of a value in the market of a large town of £75 10s., but the following year the produce did not realise £50.

ARTIFICIAL MANURE FOR FLOWER BEDS (*A Subscriber*).—For the purpose you name "Standen's Gardener's Friend" is a good manure. A sprinkling may be given over the surface of the soil at planting-out time, and should be lightly forked-in. Guano is also a good manure for flower beds. It may be applied at the time of planting out, enough being sprinkled over the surface to make it yellow, and should then be pointed-in with a fork; or it may be applied in the liquid form, 2 oz. being dissolved in a gallon of water, and a good soaking given the beds during dry weather.

TRITILETA UNIFLORA CULTURE (*Mrs. A.*).—The plant should be continued in the greenhouse, be kept in a light and airy situation, and be

well supplied with water until the growth is complete. When the leaves turn yellow, it may be planted out in the open border. It is quite hardy.

GUERNSEY AND BELLADONNA LILIES NOT FLOWERING (G. C.).—We are unable to account for the Guernsey and Belladonna Lilies not flowering, unless it be owing to their having been kept in ainery, which would not, from the shade, be a place calculated to secure the full maturation of the growth, upon which their flowering mainly depends. We would advise your keeping the plants constantly upon a light shelf in the greenhouse, placing the pots in pans full of wet sand. The sand should not at any time be allowed to become dry, not even in summer, when the plants are dormant, but at that time the latter need not be watered at the surface. Do not repot them, but keep them in the same pots until the drainage becomes defective, or they split the pots.

PEACHES FOR FORCING (Idem).—Four good Peaches for forcing are: Grosse Mignonne, Bellegarde, Royal George, and Noblesse.

PLUM TREES BLOSSOMING, BUT NOT FRUITING (N. Chapel).—We should conclude that your trees have been planted in badly-prepared ground in the first instance, and that the roots are now in ground so hard that it does not admit of the rain entering it freely. Your taking out a trench some years ago and filling it with clay rammed hard, would only tend to make the ground impervious to rain. We would advise you to dig round the tree-trenches for holding water, to make holes 2 feet deep with a crowbar, at every foot distance, and then fill the trenches with water, and keep them full for a time. Three or four waterings of this kind will be sufficient. The trenches need not exceed 6 inches in depth. When the water has subsided you may level the ground, and manure round the tree with an inch or two thick of cow dung. This should be done now.

TROPEOLUM JARRATTI NOT FLOWERING (Idem).—We can only conclude that your plant in theinery is not placed near enough the glass, and has not a light and airy situation. Afford it this, and it should flower freely.

ZINC LABELS (G. S.).—We do not know of any better means of preventing zinc labels from corroding or tarnishing than painting them with white lead, giving two thin coats, and allowing the first to dry thoroughly before the next coat is given, and then to give a coat of stiff or thick paint. Before this becomes dry, write upon the labels the name with a joiner's pencil, and the writing will be impressed in the paint on the label, and will be as enduring as the paint. Wooden labels are quite as durable as zinc, but are more conspicuous.

PAPER COVERS FOR FLOWER POTS (I. I. W.).—The paper envelopes for flower pots are sold in the Middle Row, Covent Garden Market.

VARIEGATED JAPANESE HONEYSUCKLE FLOWERING (Idem).—The variegated Japanese Honeysuckle (*Lonicera atropurpurea*) has flowered in England. As far as we are aware the first notice of its having done so appeared in page 471, Vol. X, New Series, where it is described as growing at The Laurels, Tanton, on the south wall of a greenhouse, and as being very sweet. It is quite hardy, and will succeed in the open ground; we having employed it extensively as an edging to beds, and for centres to flower beds, training it in the form of a pyramid. Though it grows freely against a wall with an east or west aspect, we think a wall with a south aspect essential for its flowering.

REMOVING WEEDS FROM ORNAMENTAL WATER (Idem).—Your mode of fixing the scythes is correct. All you want is a rope fastened at each end of the blades, and not between them, as shown in your sketch at n. You will thus require four ropes instead of two, and by pulling at two in the direction you wish the weeds cut, the machine will be prevented from turning over by the ropes being held by persons from behind, and moving as those at the other ropes draw the implement forward. It can then be drawn backwards and forwards until the weeds have been cut, and this may be repeated as often as required. This is not a bad method of keeping down weeds, but ducks, swans, and other waterfowl do so more effectually, and are ornamental as well.

CELOGYNE CRISTATA (An Orchid-Grower).—You may cultivate it either in a pot or on a block; we should prefer the former, and by pursuing the treatment named at page 90 of Vol. iv., to which you allude, we have every hope of your succeeding. You will do well to cut away the bloom buds now appearing, making sure that they are such before doing so. You should place the plant on the block, put a little fibrous peat between the roots and the block, then cover the roots lightly with sphagnum; behind the moss sprinkle a little fibrous peat, and then secure firmly with copper wire. The block for the size of plant you describe may be 1 foot long and 8 or 9 inches in breadth. You may about midsummer, if the plant be in vigorous growth, water with weak liquid manure. The wrinkles on the bulbs are due to exhaustion of some sort; probably the plant has been kept very dry before the growths were mature. It is seldom owing to the flowering.

TRANSPLANTING CHAMEROPS HUMILIS (Try).—We should take out a trench all round the plant 10 feet high with a hole 3 feet in circumference, not going nearer the stem than 3 feet, and go down as deeply as the roots. This done, with forks remove all the soil from the surface, and that parting freely from the roots, plying the forks inwards towards the stem. In this way remove all the loose soil; but when you come to where the roots and soil are very closely matted, do not attempt to remove the latter, but work under the ball from all points, and introduce under it two planks of sufficient strength to support the weight of the tree and ball. These should go completely under the ball, and extend twice the distance taken up by the ball. Two 12-foot planks, 11 inches by 3, will be required, and they should be placed under the ball so that each shall bear an equal proportion of the weight. To maintain them at the proper distance, pieces of timber may be placed across, close to the ball, on opposite sides of the tree, and the ball and tree made secure to them with ropes, having previously covered the roots or ball with mats, and otherwise taken every precaution to prevent the injurious effects of dry air and sun upon the roots. The part of the stem to which the ropes are attached should be protected with mats wrapped round it. You may then place handspikes crosswise to the planks, three on each side of the tree and, tying them to the upper side of the planks, put three men to each handspike, or, in case of necessity, four to six. By these means the tree may be raised and taken where required, or placed on a low truck and drawn by horses. Early next month will be a good time to perform the operation. Your mode of proceeding after planting appears sound, and will, no doubt, prove successful.

SOWING SEEDS OF RICINUS, ZEA JAPONICA, AND OTHER ORNAMENTAL-FOLIAGED PLANTS (York).—You should sow the seeds at once on a hot-bed, and grow the plants in heat. Prick them off when large enough, or pot-off, and shift into larger pots as those first used become filled with roots. When the plants are of a good size harden them well off before planting out, which in your locality should not be done until the beginning or middle of June.

PAINTING HURDLES (H. T.).—Nothing is so disagreeable for coating iron hurdles with as gas tar. We had many hundreds of yards of iron fencing, such as you describe, that had been daubed repeatedly with gas tar, and had become quite offensive. We had them taken up carefully and piled one above the other, putting some bricks under the bottom hurdles to keep them from the ground, and placed all round them a quantity of brushwood, which being set on fire burned the tar off. We then gave two coats of lead-coloured paint, made of white lead, lamp black, and linseed oil, and then, refixing the hurdles, brushed off with two coats of green paint.

LILIU ACRATUM (F. D.).—The bulbs of this, sold at Mr. Stevens's rooms, on the 6th inst., brought from 3*l.* to 5*s.* each, according to quality. For *Gladolus Breuchleyensis* the prices were merely nominal.

NAMES OF PLANTS (J. S.).—*Helleborus viridis*, or Green Hellebore. (R. Kemp).—We cannot name plants from descriptions of them.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending March 10th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

PROFITABLE POULTRY-KEEPING.

Nor only is there a tide in the affairs of men, but we believe there is one in poultry. Like the banner that formed or forms the subject of a contest, it rises, falls, is now to the fore, sinks, and when apparently gone rises higher, and with a better surrounding than ever. The poultry pursuit was of sufficient importance at one time to be called a "mania." This is no mean distinction. A mania takes hold of the public and the public money. That which costs nothing is unworthy of the name, and no notice is taken of it. If a man has a few thousands per year, and some glaring eccentricities, he will

soon find near relatives so anxious about his welfare, that they will get learned men of the law and of physic to ascertain whether the patient should not have his property managed for him. But in every town and village there are men notoriously of unsound mind, who have been playthings for idle fellows and children all their lives. No one cares for them. There is something akin to this in the results of these manias: a man who fails for a hundred thousand has more admirers, and is more looked up to than the plodder who pays in full all his life. No one failed for large sums during the poultry mania, but there were numbers of discontented, and plenty of people who called it "a bubble." It was neither one nor the other. It was not a mania, for at the end of twenty years the pursuit is now, perhaps, on a firmer basis than ever. It is not a bubble, for it has long passed the age of such things. There are not

wanting far-seeing people who say, that when the gold of Australia is exhausted, wool and corn will form more certain foundations of prosperity; and so we do not hesitate to tell all, that if every show in England were closed, and the "Standard of Excellence" were become obsolete, there would be a sound and profitable pursuit in keeping poultry. When a large nugget is found in Australia there is a rush of all the unemployed to the spot. It is the same when a new breed of fowls comes up. It becomes at once the attraction of all the poultry Micawbers who are waiting for something to turn up. The breed is at once invested with almost miraculous virtues, and may rank among the fortunate if it escape improvement at the hands of some of those who view it as a means of making money. There is always a large class of society that cannot bear the beaten track, nor submit to jog on among those who toil patiently, adding little to little, till they have mastered a position. They must be quick, enterprising, and shrewd. They must see advantages hidden from ordinary men, and must, of course, reap a benefit corresponding with their own estimate of their deserts. It was this spirit that caused Cochins to make fifty guineas each, sometimes more, and, it may be added, this spirit brought about the collapse that followed the mania.

There can be no doubt of the great interest now taken in poultry, we believe we may say more than was ever before shown. It had the honour to be placed among the "limited" of 1866; but fortune frowned upon it in such company. Too much was expected of it, and therefore it produced only disappointment. The present generation is evidently wiser. It is not led away by visionary schemes, nor does it believe all that is published in England as being well known abroad. The present movement bids fair to be lasting, and to produce good results. Those who have been in the habit of reading our columns will know we have foreseen this, and have predicted such a time as the present—the revival of the poultry question in its capacity for producing food. There will be no disappointment in this, for none is possible. It is only where undue expectations are raised that such a result happens.

It has been often urged, and by good authorities, that poultry will never become a staple article of food. We do not believe it will ever be sold at per lb. like beef or mutton in the markets; but we also know there is demand for a much larger quantity than the United Kingdom produces. If we should ever have that which is much wanted—a statistical account of the importations into Leadenhall and Newgate markets, many who flippantly talk about the whole question being in a nutshell, and pooh-pooh what they are pleased to call a few Turkeys and Rabbits, will be astonished at the number, weight, and value of the imports. That which was a small trade a few years since—viz., the importation of Ostend Rabbits, now counts in many thousands of pounds monthly; while they are delivered by the ton, and sold to the dealers at per stone like beef or mutton. It may be said these do not belong to poultry; granted. Eggs do; what will be said of the importation of between 4 and 500,000,000 annually? The whole north of France, all Belgium and Holland, parts of Switzerland and Italy, are put under contribution to supply the English poultry market. Those who travel in these parts will hear constant complaints at the change that has taken place. The good Goose or Turkey to be had formerly for 40 or 50 sous, now makes twice as much; while the omelette that used to be made with twenty eggs, now costs more, though it is only composed of twelve. All these come to England. Experienced Englishmen have been sent to France to superintend the killing, picking, and packing of Turkeys after the English method, while the Geese are bought lean and sent to England to fatten. This is no mania, nor is it a speculation. It is an established trade, and has lasted for years. This proves it profitable. This again is an assurance there is demand for all that is sent over. Hence two conclusions: first, that we do not produce enough; next, that there is no doubt of a sufficient demand and a sure market. We have nothing to do here with the high-flown descriptions of many who have really no real knowledge of the subject, and who will almost undertake to prove the possession of a cock and six hens a moderate livelihood. We cannot agree with those who would have people believe that any number of fowls can be kept on the smallest possible space; but we want to affirm that those who wish to keep poultry, and have moderate conveniences for it, may do so profitably.

We have sometimes treated the subject dividing table from exhibition poultry. We will now put them together. There

is no such thing as a yard where all the fowls are fit for exhibition. One strain may be better than another, but none can win without help, and without the opportunity of much selection. If it were necessary at poultry shows to give a pedigree, as it is at some agricultural shows, there would be much surprise when it was seen how the large yards were indebted to smaller ones, and how much assistance was required to form a prize pen.

Our own experience teaches us, that to exhibit successfully birds of one's own breeding, it is necessary to produce a large number and to pick from them. We are giving an account of that which has happened when we say, that in a large yard filled with the produce of the best birds money would buy, and containing only the pickings of the broods, it was almost impossible to choose a cock and two hens likely to be successful at Birmingham. A neighbour who kept only a few birds, cared for no particular strain, and left them pretty much to take their chance, supplied not only the wanting bird, but of a quality that made success a certainty. This is no isolated case. The competition of a poultry show has supplied to many a pleasing pursuit and a legitimate excitement, and needs only to be put on an inexpensive footing to be still more adopted. The belief that it is necessary to spend a great deal of money to get a prize is a mistake, and the idea that after a great number of good birds has been reared there is no sale for them, is another. As to the first it is essential to have a good walk or pen to begin with, to buy eggs from some one you can depend upon, to hatch your chickens early, and to feed them well from the first. As to the second, recent sales, Lady Holmesdale's for instance, and those at Stevens's all through the season, have proved there is a profitable sale for good birds. We are common-sense poultry-teachers, without the semblance of romance or excitement about us. We want to publish the plain things of the pursuit. We say, then, the days are passed when it may be expected to make hundreds of pounds of a yard of poultry (Lady Holmesdale's was an exception), but good birds will make good prices. We leave shows aside as regular sales, they are few and far between, very profitable when they come. When three or four pens bring £50 or £60, it is a mighty help to the balance sheet. It always gives prestige to a yard. It begins the sale of eggs for sitting. Our columns will testify to the reality and extent of that trade, we may add its profit also. If success can be held on through two years the yard obtains a name, and a dozen or eighteen birds sent in the exhibitor's name and with the guarantee they belong to him, will always meet a sale. We believe we are correct when we say, that at Stevens's rooms both Spanish and Irishmas have made £9 each within these six weeks. We dwell on auctions because they afford an easy and positive answer to that old and frequent question, What am I to do with my surplus stock? and although they do not always command large prices, they always sell without sacrifice.

The poultry pursuit was carried on for many years without any other hope or resource than the sale of eggs and fowls for food purposes, and even then it paid well. With prize money, exhibition sales, auctions, and eggs sold for sitting added, it ought to be under any circumstances profitable now. A bet was made many years ago by a Berkshire farmer to match the produce of two hens against two ewes of a celebrated flock belonging to a neighbour. The hens won. Two picture-dealers lived in the same street; both were good judges of the wares in which they dealt; both took their periodical continental trips, and when they returned were followed by buyers anxious to see their purchases. One sold whenever a profit was offered; the other, shutting himself up in his judgment, named his masters, tacked his faith to their being originals, and put a price on them accordingly. He was every now and then justified in his course, by hearing that his neighbour had sold for a few pounds a picture by an old master that was worth hundreds. In the meantime many admired his, but no one bought. He became bankrupt, the other made a fortune. The nimble nineness beat the slow sovereign. It is so with poultry. If the amateur can afford to indulge his hobby in every way, by all means let him do it, but if it does not succeed he must not complain his pursuit is unprofitable. He ceases to follow it remuneratively, but if it is to account for itself at the end of the year, then constant sales must take place.

Early eggs must be sold at good prices—assuming that the laying season terminates as a rule in September or October, it will be unreasonable to expect hens to begin to lay again in December when eggs are most valuable. Laying in winter is not the characteristic of a breed, but the result of a calculation.

Say that Dorkings or Spanish lay at seven months old, Cochins and Brahmas at six, sometimes at five, then chickens of the breeds must be kept in the spring, so that they shall attain those ages in December when eggs are scarcest. This brings it to a certainty. There are few places where new-laid eggs are not in demand at that time at 2d., in many towns they make 3d. each. In the neighbourhoods in the west-end of London where horses and carriages stand, greengrocers and small shopkeepers keep fowls under every disadvantage, but make them profitable by the sale of eggs. The same may be done by any one. This is an exceptional time of year, but we never yet knew a place where new-laid eggs were not saleable all the year round. They suffer little by foreign competition, and as soon as it is known that they are brought regularly, shopkeepers are glad to buy them. This soon amounts to a sum in the spring.

Then there is the sale of fowls. If they can be reared early they make large prices. In numbers of places poultry is given up as out of season from February till July; none but hard winter fowls are to be had, but if young ones were offered they would soon be gladly purchased. Such would be the refuse of the yard—those that were faulty in some particular. This plan enables any one to breed good and valuable fowls, because it affords the opportunity of great choice. Spring chickens, the most valuable because the scarcest, are fit for fattening at fourteen or fifteen weeks old. At that time their points are sufficiently developed to show whether they are likely to be prizetakers or not. In sorting a run, amateurs should begin by selecting for sale for table purposes all that are faulty; then take the worst of the good ones till there remain only those that are promising. There is not so much difficulty in rearing early chickens as folks imagine. Our experience is, that they are reared more easily in January and February than in March and April. The advantages are many. It enables us to give more attention to those that are likeliest to make the best return; it economises food; it prevents the evils of overstocking, and it keeps up a little supply of ready money. When the selected are attaining a size that justifies another weeding, then send the least promising to the auction. Reserve the best for exhibition and for stock. They may be put at prices that are highly remunerative without being prohibitory, and they will sell, though, perhaps, they may not be prizetakers.

One thing only is wanting, the false pride that is above selling eggs or poultry must be conquered, and the business must be looked after carefully as any other trade or pursuit is that is expected to be successful.—X. Y. Z.

LIGHT BRAHMA POOTRAS.

As a breeder of Light Brahmas for the last fifteen years, I beg to corroborate generally "Nemo's" remarks as to the requirements to be sought for by judges. In the first place, the single-combed Brahmas are as pure as the pea-combed, if not of a purer strain. For twelve years I never had a pea-combed chicken from single-combed birds; after that time, having introduced a cross with a pea-combed strain, I cannot speak so positively; but I venture to affirm that the single-combed Light Brahmas are hardier, better shaped, and better coloured than most of the pea-combed strains.

With Mr. Crook, I say that the Light Brahmas should have a surface colour of clear white, with a ground colour of grey, and, indeed, I should feel inclined to regard a bird as disqualified which did not possess the dark ground colour, as being a cross from a White Cochins. The neck hackles should be well and clearly marked; not a poor, half-marked grey, but a bold, well-defined, striped hackle.

As regards saddle hackle, I believe Mr. Crook and I are at issue, he preferring a well-marked saddle hackle also, whilst I have always bred (until my cross mentioned above), birds with a pure white saddle hackle. With the exception of the flight feathers in the wing, the black white-edged tail, and the hackles (neck or saddle), I venture to submit there ought not to be a coloured feather of any description in a Light Brahma. On the whole, I think they are rather longer-legged than Dark Brahmas, but for the table no bird is equal in flavour to a Light Brahma.—F. POWELL, *Knarsborough*.

Those who favour the Dark birds seem to me to assume that the Light, as a class, are decidedly inferior to the Dark, but I cannot see that they are at all justified in such an assumption.

I readily admit that if you look at the classes separately, the

Dark birds seem the finer; but we should not rest here without further investigation, and, above all, an impartial one; for if we do, we only foster the popular delusion, "that the Light are very pretty birds, but that the more competent a person is to judge, the more certain is he to prefer the Dark."

I believe the main reason why this delusion has arisen is, that any Light-coloured bird corresponding in all points with a Dark one, will not produce the same effect on the eye, the dark outline being more striking. This is the chief reason why the judges at our shows, who must necessarily make their awards according to the impressions they receive at the time, always decide in favour of the Dark. But it is not always first impressions that are most correct; that they are not so in this case we may infer from what we have lately read in *THE JOURNAL OF HORTICULTURE*. I think that after what has arisen, no first-class breeder will be surprised at Mr. Crook's challenge, and all must feel that no one would be likely to beat him, unless it were Mr. Boyle.

I was to-day looking over the yard of an old breeder of the Light variety. I think I never saw a prettier sight than this collection of birds with their well-defined hackles and black tails contrasting with their snow-white bodies, their broad sterns abundantly covered with a delicate white fluff. The birds looked so fine that ever since I have been wondering how the prejudice against them could have arisen, and what cause there could possibly be for its continuance. It cannot be owing to any deficiency in their weight, for there they are pretty equal to their Dark brethren. The only cock bird which I have, more than a year old, weighs 12 lbs. I do not mention this as being an extraordinary weight for a bird of this variety, but to show that they are not inferior to the other variety in this particular. Although I am continually exhibiting, I never brought forward the bird I mentioned more than once, that was at Hastings, when he was second in the adult class. He did not then strike me as being decidedly superior to the birds in the other pens as to size. Now, I do not think the average weight of the Dark birds is higher than 12 lbs., but if it is, we are ready to grant that this is in their favour, still we must be shown it first.

Complaints have been made with regard to the feathering of the Light birds, but apparently without just grounds, at least as regards its quantity, for in every well-filled class there are birds to be seen with massive wings on their backs and feet; not that I maintain that this is right, for I like to see their hocks covered with a rich round knob of soft feathers, clearly separated from those on the feet, which should be adorned with soft feathers, both black and white, well laid on, and very much corresponding to those on the breast. I am surprised that the awkwardly stiff feathering, which seems to incumber the bird rather than belong to it as a natural part of itself, should be aimed at by so many breeders; but as this applies to the Dark as well as the Light birds, it cannot be said to raise them above their more beautiful brethren.—H. M. MAXNARD, *Holmewood, Ryde*.

RAILWAY CHARGES.

I AM sorry the Honorary Secretary of Weston Show impugns the correctness of my statement—that the Secretary of the Show charged me 5s. 3d. for conveyance of birds from the Show to the station.

I beg to say—1st, That I received a letter from the Secretary, in which he says the 5s. 3d. claimed is "for carriage from the Show to the station." 2nd, That my fowls were booked through to Weston, and that there was no question, therefore, on the subject of the Secretary of the Show paying any carriage for me. 3rd, That from the letter of Mr. Percival, of Peckham, in your issue of February 6th, page 119-20, it appears that he was charged 4s. 4d. as "railway charges to and from the showyard," and that no denial of that statement has been made. And 4th, That the report in your issue of January 9th commented on the "great inexperience shown in the management of Weston Show."

As now we have evidence of two exhibitors being charged very high for conveyance from the Show to the station, the management ought to advertise their willingness to return such erroneous charges.—BRAHMA.

TRIMMING FOWLS FOR EXHIBITION.

In your impression of the 20th ult., Mr. Worthington opens up the subject of the fairness or not of trimming fowls' legs

for exhibition. I tried to get some opinion from you a few weeks ago as to the honesty of trimming Spanish fowls' faces for exhibition. I hope, therefore, if attention is called to the one, the other will not be neglected; it is a question of great importance, as tender-conscientious exhibitors have not the same advantage as those who are not so; and, again, a person may purchase a fowl trusting to the honesty of the owner, and after a few weeks have the mortification of seeing feathers come abundantly, and this from a prize fowl. I have been dealt with like this myself, so do not bring forward an imaginary ease. It tends, too, to degenerate the breeds, and to bring poultry-breeding to a low level. Under these circumstances I hope you will give your assistance in sifting the case.—A. H. D.

[We do not think it necessary to repeat our often-expressed condemnation of the practice; but as you ask us so to do, we again say that we consider any trimming of a fowl, except the recognised dubbing of Game fowls, is dishonest. That this is the opinion of poultry judges is evidenced by their disqualifying trimmed birds when the trimming is detected.—Eps.]

UNION OF THE PHILOPERISTERON AND THE NATIONAL COLUMBARIAN SOCIETIES.

THE amalgamation of the above Societies has long been looked forward to as a means of establishing the Pigeon fancy generally, and in the metropolis particularly, on a firmer and more comprehensive basis. The following Report, called for by both Institutions, has supplied a bond of union, and has been unanimously adopted:—

GENTLEMEN,—It will be in the recollection of many members of the Philoperisteron and the National Columbarian Societies, that for some time past a growing feeling of dissatisfaction has been manifested, not only in regard to the objects and constitution of their Societies and other institutions of kindred character, but also in reference to a variety of matters incidental to Pigeon culture generally. Some form and consistence has been given to this feeling by the late discussions introduced, after due notice, at both Societies, on the subjects of establishing the Pigeon fancy in London on a reorganised basis, and the desirability of forming *one* general Society with a more comprehensive constitution. These discussions resulted in the appointment of a joint Committee, representing both the leading metropolitan Societies and every practical department of Pigeon culture; Messrs. Esquilant, Wicking, and Percival acting for the Philoperisteron Society; Messrs. Jones, Ord, and Jayne for the National Columbarian Society; and Messrs. Betty, Merck, and Volckman for both Societies.

Your Committee, then, in approaching their interesting duties, and in endeavouring to report and advise on the basis on which it would be desirable to amalgamate the old Societies or erect a new one, have found it imperative briefly to review the modern history of Pigeon culture, especially on the side of its public relations and estimation.

It will not be beyond the memory of many esteemed fanciers, that years ago a stigma most intolerant and degrading was affixed to any and every matter in connection with Pigeon-fancying—a stigma, indeed, not wholly unreasonable in view of the low associations and merely pot-house character with which this artistic recreation was then encumbered. But under the worst of circumstances this naturalistic department was never left without a few persevering votaries with courage enough to scorn mere prejudice, and energy more than sufficient to rescue their pastime from every possible reproach—gentlemen whose society we yet enjoy, and to whom we owe it that we can resent as an impertinence any and every attempt to ignore our pretensions to the same standing and consideration conceded to floriculture and other amusements of similar character. Whatever, therefore, of mere blackguardism, dishonesty, or equivocal association once existed (or in a degree may still exist), the elements of reform were never wholly wanting.

Nor will it be matter for surprise that such improvement when embodied took a form highly conservative, exclusive, and re-actionary. Under the circumstances this was but natural, and was clearly necessitated by those adverse conditions to which your Committee have referred.

The formation of the Philoperisteron Society just twenty-one years ago was the first embodiment of such reform. And the Committee would here remark, that the very first experience of this Institution demonstrates unmistakably the necessity for the reform itself, and illustrates to the utmost the low estimation in which Pigeon culture and Pigeon-fanciers were held; for with whatever ease the Society took to itself a "name," its search for a "local habitation" was by no means so successful. That a Pigeon-fancier should aspire to the society of gentlemen (even the gentlemen of a third-class hotel), was effrontery too daring, impudence too intolerable; thus, members of the highest respectability, who to-day are assembled in the wide-renowned "Freemasons," were hustled rather than bowed out of many a tavern in which they sought the convenience of a room for their monthly meetings—many a place, indeed, which now would not be considered eligible for our present purposes or position.

It would be superfluous to recite the oft-told history of the Philoperisteron Society; suffice it to say, that its constitution and labours effected a substantial and growing, though not a rapid, reform; supplied the means of social intercourse amongst respectable fanciers, and won a measure of public esteem never before accorded to Pigeon culture or its votaries. In the practical department the Society has fostered and expanded the taste of fanciers, and its members have bred and exhibited the choicest specimens ever seen in almost every variety of Pigeons.

Perhaps, however, the surest indication of success may be found in the fact that the Society, in some measure, may be looked upon as a parent Society; for the impetus it gave to the whole subject developed the necessity for a yet more inclusive association, and the growing necessities of metropolitan fanciers at last found their answer in the formation of the National Columbarian Society, a Society in many ways thoroughly worthy of its ancestry, and several of whose members are members of both Societies.

We are now brought to a review of the *present* position of fanciers and their art in public esteem.

Although it must be conceded that very great advances have been made, especially on the score of tone and respectability, and although our recreation is not simply tolerated, but is widely and generally approved and admired, yet such advances in the higher senses of the term are still largely undeveloped, and much that is equivocal remains for redress or discouragement. This is evident in the fact, that numbers of fanciers, gentlemen and even ladies of intelligence, enthusiasm, position, and liberality, still hold aloof from any recognised or corporate relations with their brother fanciers. Reasons for this may be found in abundance. It is not that any social stigma any longer attaches to us or our objects—that has long ago been rectified. It is because we are failing to interest and failing in many ways to complete the reformation so worthily begun.

This, again, will be very apparent on comparison of Pigeon culture and Pigeon societies with other kindred amusements—for instance, floriculture, horticulture, &c. These departments of naturalistic recreation are progressive, intelligent, scientific, and developed in character. They can boast a literature and detail of great importance; their Societies are invested with many and varied features of interest, and, therefore, are in the highest degree attractive and influential.

Pigeon culture, on the other hand, although of most ancient date, although of eminent interest and enthusiastically practised, still lacks almost every element of progressive success. As yet it is essentially undeveloped, unscientific, wanting in dignity and intelligence, boasting no literature of adequate extent, character, or accuracy. It is failing to utilise the immense resources of interest which it commands, it is still disgraced by many associations more than questionable, and still lacks, therefore, those incentives to corporate union which have done so much for the advancement, repute, and influence of kindred Societies.

Your Committee are of opinion that these evils are intensified by the division into two Societies of a constituency far too small to bear sub-division at all; and they are further of opinion that while such division exists, no purpose, however desirable, can be effectively pursued, in consequence of the inherent weakness incident to such division.

Your Committee feel, too, that little or no excuse exists for so disunited a policy. A large number of members are common to both Societies; the constitution, objects, and practices of both Institutions are identical. Much complaint, too, very reasonably arises on the score of loss of time and expenditure. A gentleman anxious to be on terms of acquaintance with the leading metropolitan fanciers must now join two societies, pay two subscriptions, attend double the number of meetings, exhibit every bird twice, at probably much inconvenience to himself if not injury to his stud.

The results are obvious. Although the subscriptions are paid readily enough, their division into two distinct funds renders them almost inoperative for good. Both Societies suffer in many other ways. Meetings are shorn of almost every feature of interest, are badly attended, birds are not shown, papers cannot be read, discussions are not introduced. The allegiance of members being thus divided and weakened, a general blankness and lukewarmness prevail, and becoming more and more irksome.

It is high time, therefore, to inaugurate a more trenchant and united policy, and your Committee can see no reason why a system more progressive should not supersede the present condition of stagnation and inaction. Why, they inquire, should there not be facilities, as in the domains of floriculture, for the introduction of more improving elements? Are we so far ahead that there is nothing left for a Huxley, a Darwin, or an Owen to teach us? Have we, even in the humbler departments of our recreation, so completely exhausted every field of interest, that there is nothing left for investigation, and no items of mischief for redress or eradication? In an age when even recreation itself is expected to include some features of intelligence and worth, your Committee are of opinion that fanciers will not be true to themselves if they omit to enlarge the basis of their union, or to place themselves on a level with the patrons of other naturalistic pastimes.

And this brings us directly to a consideration of the means it is desirable to adopt in order to give renewed vigour to our present Institutions. On this subject your Committee have formed very decided opinions, and are prepared respectfully to offer most earnest advice.

However much they may approve of union for its own sake, they feel that a mere amalgamation of the Societies they represent would in itself be powerless to effect any radical change. It has already been stated that the practices and constitutions of both Societies are identical, and, it may be added with equal truth, are totally inadequate to the examination and settlement of the questions under review. Neither Institution can boast anything beyond the most meagre arrangements for social intercourse; while the opportunities for discussion are of the most flimsy, not to say delusive character.

In every other respect the constitutions in question are far too contracted for the growing requirements of our recreation, and stand condemned by the indifference with which members treat any advantages they may offer.

Your Committee, therefore, propose and earnestly recommend a scheme of thorough reorganisation as indispensable to the awakening of new interest, and as paramount in importance to any scheme of mere amalgamation. Such reorganisation might and should include the union of our two Societies on a basis at once comprehensive and progressive, and with a constitution sufficiently broad to secure the intelligent consideration of any and every matter of moment relating to Pigeon culture. In view of the ample materials which exist for the energy and occupation of every member, and in consideration of the objects proper to such a Society, your Committee are of opinion that the proposed reorganisation should include the following matters as prominent features of its scheme:—The formation of a literature adequate and accurate in character, and the diffusion of useful information; the development of an internal public opinion for the reform of abuses; the formation of authoritative standards for all the important varieties of Pigeons; the better classification of prize lists; the improvement of judging.

Such a Society should also undertake and establish a grand metropolitan competitive show as an annual feature of its scheme; should be a tribunal for the investigation and authoritative settlement of controverted questions within prescribed limits; should develop and encourage proper methods of breeding; should discourage diffuse and unscientific breeding; should consider the mischief arising from indiscriminate exhibition, and the deterioration going on in almost every strain; should assist beginners in their formation of a stud, and thus protect them from loss, disappointment, and the designs of unscrupulous sellers.

Such a Society should also include the fullest opportunities for orderly discussion, and should invite papers from experienced fanciers, naturalists, physiologists, and other men of science on any and every matter directly or indirectly relating to Pigeon culture, its advancement, or past history; should enlist the arts of painting and photography; should encourage and keep up communications with provincial and foreign societies, and thus centralise and consolidate the fancy throughout the kingdom. Such a Society, in addition to the facilities at present offered to subscribers, should also arrange for the enrolment of honorary members, especially gentlemen of naturalistic science, and should afford every convenience for the occasional introduction of visitors; should keep careful records of its transactions, and do all in its power to place its objects on an equality with other naturalistic pastimes.

Such, then, briefly, is the scheme your Committee are prepared to recommend. If at the first glance it may appear too comprehensive, they urge that it by no means implies that all and everything they have proposed should at once find exposition or development. Their object is rather to make proposals sufficiently broad to appeal to workers in every department, however varied their taste or inclination, so that no item of advancement or improvement may be wasted for want of opportunity or encouragement.

But little need be said as to the practicability of this scheme. Its prompt initiation may be compassed by the union of the Philopisteron and the National Columbarian Societies under a constitution and code of regulations expansive enough to include the suggestions of this Report. The two Institutions thus united would form a centre of no inconsiderable attraction, not only to the fanciers of the metropolis, but of the kingdom, in view of our present and increasing strength in country members. And your Committee again submit, that the strong feeling in favour of union, together with the fact that many gentlemen are already members of both Societies, is evidence sufficient to justify such amalgamation. They are convinced, too, that their scheme of a thorough reorganisation, coupled with amalgamation, will not only advantage both Societies, but will be of untold benefit to the art generally; and will be accepted as a boon by all intelligent fanciers, many of whom have long felt the necessity for an Institution more authoritative and dignified in character than can be found amongst existing Societies.

In conclusion, your Committee beg to express the pleasure they have had in accomplishing the important task entrusted to them. While they see in the past much of difficultly vanquished, and much of success achieved, they look to the future with a measure of expectation amounting to assurance, for advancement in those yet wider fields of effort and amusement which remain to be traversed, convinced also, that a yet more discriminating appreciation will be accorded to the captivating branch of naturalistic recreation which so long and so deservedly has been our bond of pleasure and fellowship.

Signed for the Reorganisation Committee, W. VOLCKMAN, Hon. Sec.

[We are very glad at this movement, for union imparts

strength. We recommend Pigeon-fanciers generally to support the new Society, and we shall readily find space for any relative suggestions.—Eus.]

BREEDING POUTER PIGEONS—CANKER AND ROUP.

I READ over carefully Mr. Volckman's article on Pouter-breeding, which appeared in your columns on the 6th of February. As an old fancier, I must say that I cannot agree with his remarks on breeding for colour.

I have had considerable experience in Pouter-breeding during the last thirty years, and have during that time seen the fancy for those elegant birds sink until it seemed almost lost, but for three or four who stood steadily by it; but now it has risen higher than ever, and long may it continue to gain ground; for if, as some or rather most writers say, the fancy breeds are all derived from the Blue Rock, then, I think, the Pouter is entitled to be considered the most wonderful of the whole, showing such size, beauty of form, and colour, with the stately walk so very different from the "pottering" style of the other sorts; and last, though not least, his extraordinary crop which he can display at pleasure.

Mr. Volckman seems to take it for granted that colour has to a great extent been lost. In this I cannot agree with him, unless, perhaps, in the case of Red Pied birds; they, certainly, as a class are not so good in colour as they were twenty-five or thirty years ago. This I am convinced has been caused by crossing with blue, and a very ugly colour it produces. Blacks, Blues, and Yellows are all in my opinion as good as they have ever been.

In one respect, however, I quite agree with Mr. Volckman, and that is, that marking has fallen off very much, which is certainly to be regretted, as a fine bird is so much more pleasant to the eye when regularly pied. The bib in particular is now very often wanting, and bishop wings by far too common, but a few years' care will bring them up in this respect. Foul legs I also think are more to be seen than formerly, and a great blemish they are. At one time this was almost confined to Black Pied birds, and it seems to have been the case as far back as Moore's time, and to have been so common in Blacks that he says it was not much heeded, unless very bad. I have done all in my power to breed clean-limbed birds of this colour, but must confess that I have not succeeded; indeed, with only two or three exceptions I have never seen a well-pied Black Pouter with perfectly clean thighs, unless in show pens. Birds that are too gay, have too much white on the wings or crop, are always clean-limbed.

Mr. Volckman is of opinion that Mealy and Chequer birds have injured the colours. Now, I do not think this has ever been the case where birds have been properly matched, it all depends upon this; but I can assure Mr. Volckman that many of the finest birds that have been bred in Scotland have been from Mealy, Chequer, or Sandy birds, matched with birds of the standard colours. Some colours will not do long without crossing. Yellows, for instance, bred together soon become pale and faded-looking, but a well-selected Red improves the colour at once. I think I have tried nearly every cross in colours. The worst result was from Black and Yellow, so bad that I must say I did not repeat it often. The young were of a dirty, sooty, Chequer hue.

Mr. Volckman says that many of our birds are too long in feather for the length of limb. This we are quite aware of; but he is, perhaps, not aware that when the Scotch fanciers began the breeding of Pouters, they had little better than Pouting Horsemen to commence with, but now they mean to turn their attention more to length of limb and marking. The former will require both time and skill, the latter will be more easily managed. I have often heard of birds 7½ and 7¾ inches in limb, but never happened to see them.

I hope Mr. Volckman will give the method of breeding he so strongly recommends a trial, and let his brother fanciers know the result; but for my own part I do not think we can throw aside Mealy, Sandy, Chequer, or Splash birds, any more than the Almond-fancier can dispense with Kites, Duns, Grizzles, &c., though he may have a large stock of good Almond-feathered birds.

On looking at a Canary-fancier's stock lately (I am not a fancier myself), I very much admired the yellow birds in preference to the buff or white, and asked how he did not keep yellows only. His reply was, that they could not get on without the light-coloured birds; they would all run to "weeds,"

he said, if yellows were bred together. I may also mention Carriers and Barbs as proofs in favour of my opinion, as breeders match the best Blacks with Duns without injury to Blacks. The result of my own experience, therefore, is, that we cannot dispense with the colours which Mr. Volkman says should now be thrown aside as having been used more than enough already.

I always use Splash birds more or less for breeding Whites, as I find I obtain finer birds in size and shape than from Whites alone, and if the right sort of Splash is used very few marked birds will be produced.

Before concluding, I should like to say a word on the question of infection. I am quite of Mr. Huie's opinion, that roup and canker are not infectious.

Canker in my birds, I am glad to say, I have never been much troubled with, but now and then a case has occurred, but never spread, though left with my other birds.

Roup my birds have suffered very much from. I do not think, however, that it is now nearly so virulent in character as when it first appeared in Scotland about fifteen years ago. Till then it was unknown to the fancy here, and for a year or two almost every bird attacked died; no treatment had any effect. Now, I believe it is often cured; but whether this is owing to superior treatment, or to the disease being in a milder form, I cannot take upon me to say. Something, very likely, is due to both.—GEORGE URE, *Rosebank, Dundee*.

P.S.—Mr. Volkman takes care to let us know that he has had a long practical experience with this class of birds. Such being the case, why has he not given even a single fact from all this experience? I think he ought to have done so before condemning so hastily. I might almost say rudely, the method of breeding followed by the oldest and most successful Pouter-breeders.—G. U.

MR. HUIE'S criticism on Mr. Tegetmeier's book entitled "Pigeons," in which I fully concur, has been the means of commencing much-needed and most useful discussions in your valuable Journal, and I hope that they will extend until all the varieties of Pigeons have been fully discussed. As there is much still left to be said in connection with Pouters, my remarks will be on that grand bird.

I quite agree with Mr. Huie when he condemns some of the crosses in colour recommended by Mr. Tegetmeier, such as crossing a Blue Pouter and a Red, or a Mealy and a Yellow. Any good fancier who has tried the experiment will not repeat it in a hurry, or recommend others to do so; and I was very much astonished and disgusted to find such advice given in a book said to be written "for the use of the Pigeon-fancier." No experienced fancier, at all events in Scotland, has any "slavish fear of breeding away from some one particular colour," but to the best of their judgment they select such birds as they think suitable for producing the most perfect colours, at the same time keeping in view size and form.

I read in the Journal of the 6th ult. the remarks by Mr. Volkman, who says he has not read Mr. Tegetmeier's book; at which I feel astonished, as I did not consider any real fancier could withstand reading a work on Pigeons produced by one who has figured as judge at some of our principal shows. However, I do not think Mr. Volkman has lost anything by this neglect.

Mr. Volkman enters into this discussion "irrespective of Mr. Tegetmeier's book or its reviews," and says "the correspondence appears to be proceeding on a wrong basis." Now it appears to me that the correspondence has not only proceeded on a right basis, but that it has been fully argued and satisfactorily concluded. The question raised was merely on the matching Mealy and Yellow Pouters.

Mr. Volkman tells us that by the use of Mealies, Chequers, and Splashes we have destroyed the colours and markings in our Pouters, and that for the present they must be "rigorously discarded." On the other hand, Mr. Tegetmeier says the Pouter-fancier has a "slavish fear of breeding away from some one particular colour." Now, this is an awkward position for a young fancier to be placed in: whom is he to believe, and what is he to do? My advice would be, as we have no printed guide, to adopt neither theory, but use Mealies, Chequers, and Splashes in their proper places, and he will find to his own satisfaction, as I have done, that practical experience is safer than theory.

Mr. Volkman says, if we wish to produce "Blacks of raven brilliancy, Reds rich and lustrous," that we are now to commence the process of selection. For the information of Mr. Volkman, I have to say that the experienced Scotch fanciers

have finished this process of selection for the coming breeding season a month ago, and that they have matched-up their Pouters this season in the same manner as they have always done—viz., selecting the best colours that they have of their own breeding, or could find to purchase; but if Mr. Volkman could spare them some of the brilliant colours that he speaks about, the Scotch fanciers would feel very grateful to him; and I am sure that a fancier of "long practical experience," and having such a good theory, must now be in a position to extend a helping hand to his less fortunate brothers in the Pouter fancy.

The proper crosses for the Mealy and Yellow Pouter have been already taken up by Mr. Huie. As far as my own experience goes, and from observation in the lofts of our best Scotch breeders, I believe that the Chequer bred from Blacks should be crossed with Black only; and by following this method a Chequer Pouter will be quite as good for stock purposes as a Black, and the produce he "Blacks of raven brilliancy."

I also approve of occasionally crossing the White Pouter with the Blue. The White Pouter being constitutionally a weak bird, the produce is improved in strength by this cross; and the Blue gains in colour, as the White Pouter helps to clean out the foul feathers so often found in the limbs, &c., of the Blue Pied Pouters. It was from a cross of this description that I produced the progenitors of the White and Blue Pouters that stood first at Glasgow for more than one season.

When breeding for length of feather I would have no hesitation in selecting a small handsome hen, as I have found such to be the best breeders and to produce large birds, and I could point to a great many first-prize birds from hens of this description. Although I say a small hen, I would not have her to be under 17 inches in feather, and 6½ in limb.

It is always desirable to match what is termed a stocking-limbed bird with a rough-limbed bird, as by this means we keep the limb strong and having the proper cover of feather.

Two birds having stocking limbs matched-up are apt to produce birds spare of cover, and even birds with spindle shanks.

When matching-up Pouters for a season's breeding there are a great many points to be considered, such as length of limb, length of feather, girth, crop, colour, marking, &c. Now, as it is almost impossible to find one Pouter having all the properties, the best method is to select two birds that with both their points combined come nearest to perfection. When we do this we do all that we are able, and it is not absurd to expect a happy result. The finest-marked birds will often produce the mismarked birds. The plan I take to cure this is to destroy the bird in the nest. If this method were adopted by all our Pouter-fanciers it would soon rid the fancy of those birds complained of as having markings "wildly inaccurate." It is also advisable to have one of a pair matched-up older than the other, as a pair of young birds seldom do well the first season.

I have seldom had a case of canker among my Pouters, but find that my Short-faces are very subject to this disease. The method that I adopt to cure them is the old simple one of washing out the mouth, and then touching the affected part with caustic, also giving them occasionally a piece of butter mixed with salt. This disease is certainly not infectious.

The roup has been for years, and still is, a source of annoyance to me, particularly among my young Pouters. It attacks young birds at no particular age. I have seen birds take it when two weeks old, and again when they were breaking into their first moult, and it often hangs about them until they are reduced to skeletons, ending in something like consumption. I have tried many, almost all methods of cure, and when I thought I had found one effectual, again I was disappointed.

The treatment that I have most faith in is to keep the bird in a warm place, and in a hamper with straw, give it a teaspoonful of cod-liver oil night and morning, occasionally taking the bird in the hand, and rinsing its head through cold water. I have never found one case in which roup was infectious. For the sake of experiment I matched-up a Pouter hen very much affected with roup to a common Pigeon, and confined the pair in a pen for a couple of months, allowing them to eat and drink out of the same dishes, but the disease did not affect the cock.—M. STUART, 73, *Waterloo Street, Glasgow*.

UTILISING CONDEMNED BEES.

WITH regard to "A DEVONSHIRE BEE-KEEPER'S" useful paper on the above subject, I may mention, having the autumn before last saved from the brimstone pit the bees of two stocks,

belonging to a neighbouring cottager. I substituted a couple of young Italian queens in lieu of their own sable monarchs, placed each party in a common straw skep, having a little empty comb, at the same time administering a fair supply of "Greenock crush" syrup, and in due season was rewarded for my humanity, each colony last summer giving me four natural swarms, and by no means contemptible swarms either.

An apiarian friend chancing to call while one of the fourth swarms emerged, was positive it contained more bees than a prime black swarm he had had shortly before.—A DEVONSHIRE BEE-KEEPER.

TO WHAT DISTANCE CAN BEES PROFITABLY EXTEND THEIR FLIGHT?

I FIND it stated in reply to "A. T.," in page 180, that "the bees' honey harvest depends upon the country within a radius of five miles;" or, in other words, that a stock of bees can pasture profitably over a district of ten miles diameter! I only wish it were true, for honey harvests would in this case be vastly more abundant and far less uncertain; but unfortunately, all reliable authorities concur in limiting the profitable flight of the bee to a much more restricted area, whilst my own experience and observation impel me unhesitatingly to endorse their conclusions. Mr. Quinby and the Rev. L. L. Langstroth, who stand at the head of American apiarians, concur in stating three miles as the limit of the bee's range. The latter adds that beyond a circle of two miles radius they can store but little honey. Huber found on one occasion, that whilst his own bees were going to ruin for lack of food, those of other places at about two miles distance lived in the greatest abundance, threw numerous swarms, and filled their hives with honey; whilst Dr. Bevan believes that one English mile will be found to be the extent of the bee's flight in her ordinary excursions during the honey season. That bees cannot pasture profitably much beyond a radius of a mile, or at the outside a mile and a half from their hive, is also the conclusion arrived at by—A DEVONSHIRE BEE-KEEPER.

[Bees are known to visit an island more than four miles from the shore.—EDS.]

ARTIFICIAL SWARMING IN COMMON HIVES.

A CORRESPONDENT, "C. A. J.," commenting on my instruction in No. 361:—"The next day remove B to a new stand . . . and put A on the stance vacated by B," asks for my "reasons for not immediately placing the lives in their permanent positions." To this I reply, that it is better to let the confusion subside which naturally arises in an apiary at such times; but, chiefly, I desire to give time for as many as possible of the old bees to quit the hive A, so as to run less risk of fighting when the transfer of hives A and B takes place. If the first operation (of driving A) be performed before 10 o'clock A.M., there would be no objection to put the deserted A into B's place three or four hours later, taking care that the former is pretty well emptied of its population, and that the bees of the latter are much abroad at the time of the transfer. This is essential to success.

"C. A. J." asks further, "Does not the undeveloped brood in A run the risk of a check during the intervening night, there being so few, if any, bees in the hive?" Doubtless, there is some such risk, but I believe it to be very trifling. There will always remain a considerable number of bees, which, being in a state of excitement consequent on the loss of their queen, will keep up the temperature; but I should put the hive in a sheltered place, and throw something warm over it. My experience knows of no failure on this score, although, of course, it is conceivable.

"C. A. J." also remarks, "I presume there is a great possibility of the hive being robbed, it having no bees to defend it." A possibility there no doubt is, but I never knew an instance of it. Bees very rarely look out for plunder in May or June, being usually too fully occupied with pollen and honey-gathering at that period of the year. Of course, if those operations are attempted later in the summer, the utmost care is requisite to prevent robbery; but I strongly dissuade from all swarm-manufacture after June.

I may add here, in reply to an inquiry of another correspondent, that I usually set about swarm-making as soon after

nine o'clock as possible—as early as I can, in fact, but not before the bees are well abroad.—B. & W.

OUR LETTER BOX.

MARKING CHICKENS (Rouen).—If you wish to mark chickens so that they are easily distinguishable without catching, you may do it by having narrow strips of list sewn round their legs, loose enough to admit of growth. Different colours may mark different breeds. If you do not object to the trouble of banding, and it is not much if done when they are at roost, they may be marked by cutting alternate feathers of the wing. This is, however, only useful as long as they are chickens. The best plan we know for permanent marking is to perforate the web of the wing with a red-hot iron—a large knitting-needle will do. The mark is never effaced, and there no limit to the numbers that may be differently marked. It is done in a moment, and the birds suffer little from it. Your second question is a disputed point. Our own belief is you would have no produce from the second till the hen had laid all her eggs, and become broody. We know excellent judges and trustworthy authorities who hold a different opinion.

FOOD FOR LAYING HENS (B. B.).—Whole barley is very good. It should be given raw. If crushed, the husks should not be taken away.

FOWLS DYING SUDDENLY (T. C. H.).—There is nothing to prevent sudden death in fowls. Cocks are liable to it when crowing, hens when sitting or laying. Sitting hens should not have whole corn. Soft food is better for them. It will not be hereditary.

BRAHMAS' COMBS (Idem).—The pea comb has never been considered a disqualification in either class of Brahmas. Our experience of breeding the Dark is the same as yours, but we are bound to say the same of the Light. We never breed single-combed birds. Our belief is, they have their origin with those who are bent on making money, who obtain a pure bird at a good price, on one side, and a mate as nearly like him as possible. They sell the failures for table poultry, and those that take after the father for stock. The unfortunate purchasers soon find their acquisition is the result of a *misalliance*.

SCREE ON COCHINS' LEGS (Lutterlin).—We cannot tell you the cause. We have never seen it as a disease till this year, and always attributed it to snow. We have, however, heard of it where there has been no snow. It was always common amongst very old birds. We have, however, pullets that are now "down with it," literally. They seem to have lost all use of their legs below the thighs. We have cured some with sulphur ointment and principally vegetable diet, but we have some of which we despair.

LOCKS OF COCHIN-CHINAS (C. K. S.).—Any vulture hook would be a disqualification shown against birds free from it. That which you have figured is not a vulture hook; it is a turn in the feather common to most of the breed. You cannot have a better strain than Chase's.—B.

CAPONISING (J. G.).—We cannot detail the mode of performing this cruel and totally needless operation.

GROUND OATS.—"G. P." obtains ground oats of good quality from Messrs. J. & H. Robinson, of the Lewisham Bridge Mill, Lewisham, Kent, S.E. It is cheaper to buy by the sack or half sack than by the bushel.

CARRIER PIGEON'S EYE (J. R. J.).—Your treatment is good, but we would advise you also to wash the parts with a weak solution of alum and water.

DRAGON PIGEONS (J. T.).—We do not know where you can purchase superior birds. You must refer to our advertisements, and have the birds sent for inspection before you pay.

BIRD WITH DISEASED TONGUE (E. H. F.).—What bird is it?

PARROT SELF-PLUCKED (A. S. A.).—Never give hempseed to a Parrot. Let the bird have a tepid bath daily. This is easily done by filling a dish with the water. If he will not bathe voluntarily, pour the tepid water over him through the rose of a watering pot. Let him have nuts and apple.

TRANSFERRING TO ANOTHER HIVE (C. H. Stock).—You can only transfer your stock to a frame hive in the manner described by us in reply to "SCOTCH" in No. 318; but as this is rather too difficult a task for a novice, you had better let things remain as they are, and wait for a swarm. Payne's hives are about 2s. 6d. each, or you may, perhaps, have them made for less by a country hive-maker. Bell-glasses vary in price, according to size and the quality of the glass of which they are made.

FORMING AN ARTIFICIAL SWARM (—).—The best mode of making an artificial swarm from either a bar or frame hive is thus described in the Bee-keeper's Calendar of "The Gardener's Almanack" for 1868:—"Look over the combs during the middle of a fine day until the queen is discovered, then place the comb with her majesty upon it in the centre of an empty hive, and, if possible, support this comb on either side by two spare worker ones. Put the queen in her new domicile on the old stance, and remove the stock hive to a new position at a short distance. The returning bees will make up a good swarm, which, if the weather be favourable, will rapidly fill its hive with combs, whilst the bees in the old stock raise a queen, and all will proceed much in the same manner as if the hive had swarmed naturally." To this we may add, that the abstracted comb should be carefully examined, in order to ascertain that no queen cells are attached to it. If any be found, the queen must be transferred to another comb, and the royal embryos returned to the hive. The fatal objection to the course you propose is that all the combs built during the interregnum, which must ensue in one of the hives, will be drone combs, whose existence will prevent the colony from prospering.

OLIVECAKE FOR COWS (B. B.).—Olivecake certainly enriches the milk very much, but it does not increase the quantity. Brewers' grains, soft mashies, or similar food, tends to increase the daily yield of milk, but it becomes very poor. We have for some years given about one cake per day to half a dozen or more of our cows that seemed to require it most, and we have not experienced any bad results from its use, either in the flavour of the milk or otherwise. Perhaps there is nothing to which an unpleasant taste is imparted so easily as milk, and very possibly an over-supply of olivecake might have this effect; but we have found less cause to complain of this than anything else given to the cows to improve their yield of milk. We warn the inexperienced about the kind of cake they use; that from rape seed is very acrid and irritating, though useful as a fattening agent, and when it is mixed in any quantity with the linseed cake it is also bad. Cotton cake is nearly as bad. Good linseed cake should be obtained.

WEEKLY CALENDAR.

From observations taken near London during the last forty-one years, the average day temperature of the week is 50.5°; and its night temperature 33.0°. The greatest heat was 69°, on the 19th and 20th, 1836; and the lowest cold 16°, on the 20th, 1845. The greatest fall of rain was 1.11 inch.

HEDGES, AND SHRUBS SUITABLE FOR THEM.

NOTHING, perhaps, to the lover of Nature adds so much to the cheerful aspect of a district as the hedges by which it is intersected, and the timber and other trees with which it is clothed. The latter stand out in bold relief in the picture, while the hedges fill up those necessary lines without which there would be a certain amount of blank. A good hedge is in many instances a farmer's pride, and in this respect he looks at it in a different light from the admirer of rural scenery, to whom the more crooked the hedge and the more heterogeneous the plants of which it is composed, the more beautiful it appears; while to the farmer a hedge occupying the least possible space of ground, straight in its outline, and forming an impassable boundary to cattle, is the approach to perfection which he delights in.

During the last thirty years great progress has been made in this direction, and we may expect to see still further advances. In districts where hedges once existed in too great numbers these have been entirely swept away, and their real merits have not been spoken of, much less considered, in consequence of the many evils they engendered; yet hedges have their uses, and I hope again to see those large breadths of some of the fairest land in the realm, now only subdivided, into large compartments by an invisible wire fence, again intersected by hedges of a suitable size and form—not a confused mixture of Hazel, Maple, Elder, Willow, and various shrubs, but neat Thorn hedges, kept clean and orderly. These, although they may harbour a few birds, need not necessarily be a nursery for weeds and other evils, and it is questionable if birds to a limited extent are not rather an advantage than otherwise. Hedges, apart from their utility, are a necessary feature of the landscape in most districts. The want of them, as in the fen and marsh districts, where high cultivation exists, causes a sad blank in the winter scenery; but it is not in these cases only that I advocate their adoption, but in some of those large tracts of land, where a few years ago they occupied a space equivalent in some parishes to one-sixth of the whole area. In remedying this evil people ran to an opposite extreme, and the unmerciful annihilation of large breadths of hedge and coppice has quite altered the character of the district. In such cases a few neat well-managed hedges might be useful; and as the materials for such and the mode of managing them differ considerably in various districts, a slight notice of what appear to be the most approved may, perhaps, be of service to those intending planting.

Yew.—As an ornamental hedge this unquestionably stands first, alike for its fine appearance and durability. Yew hedges in the neighbourhood of some residences date back to a very remote period; in fact, it is difficult to place a limit to the age which this plant under favourable circumstances will attain. Hedges of it when subjected to close and severe pruning seldom live so long as those allowed more space to expand themselves, nevertheless a

Yew hedge may often be met with whose external character has shown no change for a long lifetime; possibly very accurate measurement might detect some advance in one-half or three-fourths of a century, but some venerable hedges of this plant are said to have presented but very little change during that period.

In general the Yew likes a high and dry situation, and is most frequently met with in a wild state on the exposed cliffs of our chalky hills. It is, however, very accommodating when in a cultivated condition, for it is often planted and found thriving in a soil and situation just the reverse of the above—in a stiff clay, perhaps, and is met with growing very well under trees where few other plants would live. From its dense growth and hardness it deserves to be planted more frequently in the shrubbery than it now is; and when we contrast its appearance with that of kindred foreign Conifers, as *Taxodium sempervirens*, we certainly have reason to be proud of our native Yew as excelling in every respect, excepting perhaps in altitude, all of these. It is, however, as a hedge plant that I here advocate its being planted, and as such it occupies a high position; for although its slowness of growth may in some cases be urged as a fault against it, yet in favourable situations it grows more freely than may be supposed; it bears transplanting well, and its sturdiness and elasticity are such as to prevent its suffering much from accumulations of snow. But in one respect Yew is inferior to most of the hedge plants mentioned below—it cannot be regarded as a fence against cattle, for its poisonous properties render it dangerous. Although sheep and other animals grazing on those hilly districts where it is found will feed occasionally on it with impunity, and rabbits eat it when in their way, yet domesticated animals often suffer fatally when they partake of it. When, therefore, it is necessary that the Yew should be a boundary, let it be protected by wire or other fencing from the attacks of cattle; its importance entitles it to this care, apart from the danger referred to.

HOLLY.—Next in merit, and in the opinion of many equal to it if not excelling the Yew, is the Holly, also a native plant adorning some of our woods with its glossy foliage and coral-like fruit. Its associations connected with Christmas and other festive occasions give it almost as much a claim to our veneration as the Yew. As a shrub or tree for hedges it grows more rapidly than the Yew, and forms a more impenetrable fence against bipeds and quadrupeds when it has once become fairly established. It is better adapted than the Yew for moist situations. It is also suited for forming a high rather than a low and small hedge, and is impatient of continuous cutting to a limited height; still Holly hedges are often met with in excellent condition, and some that I know may be regarded as ornaments to the district. The Holly is also more hardy in a certain sense than the Yew, being found in a wild state farther north; and I believe some of the finest Holly trees in the kingdom are in the north. The Holly, like the Yew, has the advantage of succeeding under the shade of other trees. A somewhat stiff soil, with plenty of stones in it, and not too dry, seems to suit the

Holly best. Care must be taken to prevent the plant being destroyed by rabbits, if they abound, as they are very fond of this tree. May is about the best time to plant, if the weather is not too dry at the time, and if the plants have been removed a year or two previously they will be all the better, as the Holly is not the easiest plant to remove successfully. It may be remarked that it is not bad practice to plant a Holly here and there in a Quickset hedge, say one at every 6 feet or so; the Hollies thus look cheerful, and give more shelter in winter than the Quicksets alone.

Privet.—This plant occupies a position many grades below the Yew and Holly, but it has the advantage of soon attaining the requisite size, is not particular as to soil or situation, and will bear cutting into form at any time of year. It may also be planted at almost any time; its drawbacks are its inability to support itself against heavy accumulations of snow, and that late in the winter it is almost denuded of leaves. To give it strength it is better to plant Quicksets (Whitethorn), with it, say one plant in three, and the close interlacing of its shoots partially compensates for the lack of foliage in March and April after a severe winter. The chief merits of Privet as a hedge plant are its rapid growth, the trim appearance which it presents when fresh cut, and the great accuracy with which that operation can be performed without danger to the plant; it is also less injured by rabbits and hares than the Whitethorn, but is not entirely exempt from attack where the former are numerous. Privet will thrive in almost any soil, but if planted by the side of a rich border, it will exhaust it more than is proper for the other plants. On the other hand, it will grow under trees where hardly anything else would succeed, and is on many accounts useful.

Box.—It is scarcely necessary to remark that this is still more slow of growth than the Yew, and the number of tall hedges of Box is necessarily few; but there are cases in which a low hedge is wanted, and where variety may also be desirable, and in these Box comes in useful, especially as its colour differs widely from any of the three plants previously described, and it bears cutting-in well. Box adapts itself to almost any situation; but the more shaded it is the deeper the green it presents. The varieties of Box differ considerably in their growth. The dwarfest edging Box grows very slowly indeed; I have some that was planted out in nursery rows on ground of fair quality, and which has not much exceeded the height of an ordinary edging in five years, although it has never been cut all that time, and was not very small when planted. On the other hand, some of the varieties of tree Box grow faster than others, and there are some intermediate varieties.

In general, Box thrives best where lime, either as chalk or in some other form predominates; but ordinary good garden soil answers very well. It transplants well, but always prefers an improved soil at each change, otherwise the progress is slow. The ordinary tree Box of British origin makes a better hedge than the *Majorca* species, the latter now and then succumbing to such hard winters as those of 1838, 1845, 1855, 1860, and 1867, although the injury which it sustained in these years was not the same at all places. An old Box hedge that has extended beyond its allotted space may be cropped-in almost to the naked stems of the central upright shoots, and fresh shoots will be produced, provided one side of the hedge be cut at a time, so as always to preserve sufficient foliage to keep the plant healthy. A fresh growth may be secured by this means in two years or so. Unlike most of our indigenous plants, the Box does not reproduce itself to any great extent naturally by seeds, excepting in favoured situations. I believe that on the chalky hills in the neighbourhood of Dorking it is so produced; but in many places where the plant even thrives and does well, the quantity of seed furnished is very small.

LAURUSTINUS.—As an ornamental bank or line, this is well worthy of a place, but it must not be cut so exactly to form as the preceding plants, otherwise the bloom will be destroyed; it likewise requires to be allowed a greater width for growth, and its top ought to be rounded. The *Laurustinus* does best in dry ground, ripening its shoots better, and withstanding the winter better. Very severe winters, however, injure it, such as that of 1866-67, when so many plants were killed in various places; even here some were much injured, while others were scarcely in the least affected, and ripened their summer growth and commenced flowering in August. This plant, however, is more tender than most of those previously named, and is not so well adapted for the formal trimmed hedge; but for a screen to hide unsightly objects it is excellent, and its flowers are at all times interesting, more especially

when they are produced in a mild winter, giving cheerfulness at a time when flowers, excepting under glass, are few and far between.

COMMON LAUREL.—This is a sturdier plant than the last, being seldom injured by snow or frosts in the south of England, although it was so very much last year; it will also bear cutting to any shape. It ought not to be cut with the shears, although this is often done; but the knife makes better work, not severing the large leaves like the shears. It grows rather fast, and is not particular as to ground, although the better that is the faster it grows. Usually dry stony ground, with a subsoil favourable to roots descending a good depth, is the best for the common Laurel.

The best time, perhaps, for cutting a Laurel hedge or bank is the end of July, after which a small amount of growth takes place, which affords additional foliage to the hedge for the winter. The shoots thus produced, being mostly about 3 inches long, if the ground is dry will ripen to their tops and look as perfect as if cut to the size; but if any of undue length appear they may be cut out with the knife in the autumn. The hedge or bank will consequently look well all the winter and spring, up to the time when growth takes place again early in the summer. For some years I have managed some Laurel banks here in this way, and find that from the middle to the end of July is the best time for cutting them. Of course some attention is paid to the character of the season, but in general the above is the best time. If the Laurels are cut earlier the aftergrowth is more than is wanted; while, if cut later, there is not sufficient aftergrowth to clothe the cut portion of the hedge, which will consequently appear raw and naked. It is scarcely necessary to remark that a wet autumn, and possibly a wet situation, will prevent these autumn shoots ripening well; but as a rule they do so when the soil is dry, and when the plants upon it exhaust all its moisture, as is usually the case with the Laurel. It grows faster than the *Laurustinus*, and is capable of being formed into any shape; but when a steep bank has to be covered, alternate slopes and perpendiculars look best.—J. ROBSON.

(To be continued.)

DISA GRANDIFLORA CULTURE.

A STATEMENT copied from a French contemporary relative to this beautiful Orchid induces me to say a few words about it, for it is a marvel to me that it is not more generally cultivated, as there is nothing more beautiful than it is when well grown, and there is no plant more easily managed; and yet, strange to say, one very rarely sees it, and even when seen it is not in the flourishing condition it ought to be. I have had now some years' experience in growing it, and as my plants are the admiration of all my neighbours, I may be allowed to speak from experience.

The statement to which I allude was that the writer had succeeded in making it produce three or four blooms, and had induced the same plant to flower three or four times. I wrote a few lines about it; but even with the Editor's remarks thereon I cannot see what the Frenchman did or did not do. As to producing three or four flowers, I have had it with six; and I believe Mr. Leach, of Clapham Park, who first taught us the way to grow it, and who gave me my plants, has had eight or nine. But what the meaning of the second feat is I do not know. The habit of the plant is peculiar. It throws up one stout shoot; the shoot gradually develops itself into a flowering shoot, while at the same time the young shoot which is to form next year's plant appears alongside of it. This stem having flowered, gradually begins to rot away, and at last comes off from the plant just below the surface, and the next year's shoot takes its place. Now, if the Frenchman says he made this flowering stem produce flowers four or five times, I simply do not believe him; if he means that the same plant flowers again next year, I do not see that there is much in that, for it might go on in this way indefinitely. My short note brought me one from Mr. Leach, who says the "Frenchman does not seem to have done any great wonders."

As to soil, I have used a mixture of peat and cocoa-nut fibre and sand. Mr. Leach uses peat, and says, "I am somewhat astonished at your continuing to use cocoa-nut fibre. I have never ventured to try it with *Disa*. With other Orchids I used it for a time freely, but after six or eight months I was glad to take the plants out of it and fall back on the peat and sphagnum." This has not been my experience this year. I have one large Italian pan in which there are three or four

good-sized plants, and I have not disturbed it this year at all, but merely took off the surface to the depth of an inch or more, and top-dressed with the same compost. Nothing can be doing better. The pan is filled with offsets, and the flowering stems for this year are fully an inch in diameter, so that I expect each of them to bear at least six or seven blooms. I seeded one plant in the autumn of 1866, and in consequence I believe nearly lost it. I, however, divided it, did not allow it to develop its flowers last year, and now it seems to be thriving as well as the others. I never induced any of the seed to grow; but Mr. Leach informs me that he has a few little seedlings "large enough to be seen without spectacles," the produce of seed sown in 1866, and that he has another pot with a multitude of plants in it from seed of last November or October, as yet so diminutive as almost to require a microscope to see them. He adds that there is no difficulty in raising them, and hence *Disa grandiflora* ought to be in everybody's possession. D., Deal.

CENTAUREA CANDIDISSIMA PROPAGATION.

As my method of propagating the above plant differs materially from those of your correspondents in your last week's issue, I send an account of it for publication, hoping they will give it a fair trial, and I have no doubt of a satisfactory result. In the month of August I select a sunny, yet sheltered spot, under a wall or a similar place, and take out the soil 9 inches deep and 18 inches in width, level the bottom, and put in 6 inches of drainage with the same care as if for a valuable stove plant. On this I place an inch of leaf mould, then a mixture of loam, leaf mould, and coarse white sand in equal proportions, all sifted; in this I place the cuttings.

Now, if the *Centaurea* has had favourable treatment in the flower garden, it will be very much increased in bulk by the third week in August, and each plant will afford two cuttings, some three or four, without damaging its appearance if selected carefully. Cut them off with a sharp knife, regardless of a heel to them, for I find this is not necessary. Take off a portion of their leaves, say four out of twelve, and prick the cuttings in the soil previously prepared for them, 3 inches apart each way. Let them have the benefit of the sun and dewy nights, but protect from heavy showers and frosts if they occur. By the middle of October the major part will be rooted; those that are not so will be callused, and may be treated as the rooted plants without much loss.

In taking them up great care is necessary. I dig a trench close to the first row, and by a little contriving the cuttings are undermined and taken out carefully, when the roots will be found clinging to the leaf mould. They are then potted in a similar soil to that in which they were struck, but a little coarser, and plunged in a half-spent dung bed in any porous material, where they must have air night and day, regulated according to the weather, but on no account must they be shut up closely. I find this plant will not do without air at all times.

The old plants when taken up may be treated similarly, or they will do if plunged in coal ashes, but not so well as with a little dryish heat.

When established all may be placed on a front stage in any house where they can have abundance of sunshine and plenty of dry cool air.

In January I select a number of the strongest plants and place them in heat, such as a vinery at work. When they show signs of growth, which will be in a fortnight, the strongest side shoots are taken off as far away from the stem as possible; the advantage of this will be seen hereafter. Prepare them similarly to the August cuttings, and let each have a 72-pot to itself; plunge them in bottom heat and they will soon strike. In three weeks there will be numerous shoots sprouting out from the stems where the first cuttings were taken off. When these have about five leaves pull them off, and place about nine in a 5-inch pot. Treat as advised for the others until established, when they should be hardened-off by degrees.

It will be seen that by my method the cultivator has two chances of propagation; but I have always found spring to be the best time, as I obtain three crops of cuttings, and the autumn affords only one. Besides, I have found that to cut the plants up into cuttings in autumn is to run the risk of losing the lot, for the old plants are likely to die through being mutilated so near the winter.

Has any correspondent seen disease in this plant when planted in masses of two or three hundred? It has occurred

here, but never when the plants were in single or double rows, and I have attributed it to the want of a circulation of air to dry the foliage after rain. Disease has always made its appearance when the plants are thickly together, and it is always in the centre of the mass.—THOMAS RECOR, *Hawkhurst, Kent*.

SOWING ORCHID SEED.

You were so kind as to answer my inquiry respecting the seed pods on the *Odontoglossum grande*. The pod, which was the size of a hen's egg, and has remained on the plant for two years, broke open this morning (March 10th), and has shed a large quantity of cream-coloured seed, not unlike Poppy seed. The question now is, How is it to be sown? My gardener thinks it ought to be sown on chopped sphagnum and turfy peat, and covered with glass in the stove or propagating pit.

As the plant was standing between *Laelias* that were in splendid bloom at the same time, my man took a little of the pollen from *L. superba* with a camel's-hair brush, and impregnated the bloom of the *Odontoglossum*; this he thinks has caused it to seed.—H. M.

[The best reply we can offer to this inquiry is in the following extract from Williams's "Orchid-Grower's Manual":—

"The best place to sow is on the top of an Orchid pot, where the seeds will not get disturbed; let the peat be in a rough state; do not cover the seed, but give a little water with a fine-rosed pot, just to settle it in the peat; some rough blocks of wood on which another plant is growing afford a capital situation to grow upon; they should always be kept a little moist; and of such as are sown on pots in the same way, when the plants are strong enough, pot them off into separate pots, or place on blocks in material already recommended; in potting and taking them up, care must be taken not to break the roots; by hybridising the finer kinds you are most certain to get fine flowers. Of *Cattleyas* we have only one which is not worth growing, and that is *C. Forbesii*, yet that is better than many other Orchids in cultivation; therefore, let many begin to raise hybrids, not only with the view of obtaining finer flowers than we already possess—though that would be a real acquisition—but for the additional purpose of raising sorts that might succeed in cooler houses. *Odontoglossum grande* and many others, for instance, do better in a cool house than in a warm one. *Cypripedium insignis* will also thrive well in a greenhouse. If, therefore, we could cross this with some of the other kinds, such as *C. grandiflorum*, *C. hirsutissimum*, *C. Lowii*, or *C. barbatum* superbum, something good might be the result. There is also our hardy *Cypripedium spectabile*, which might be induced to play an important part in the operation. *Phajus grandifolius* and *Wallichii* are likewise two noble plants for winter decoration which do well in a warm greenhouse. Might not these be crossed with *albus* and *Bensonii*, the one being white, and the other lilac, and something new be realised, provided they could be had in flower at the same time? I am glad to be able to state that we have numerous Orchid-growers trying their hand at seedlings, and many of them have succeeded in raising some, and I hope to see something startling in that way before long. Moreover, *Lycaste* will do in a cool house, as, for instance, *L. Skinneri*, which is one of the finest."

CULTURE OF STOCKS.

HAVING been very successful in the raising of Stocks, I offer a few hints on the system I adopt.

I use rich friable soil, such as would grow a *Pelargonium* well, keeping the finer portion for the top. I then sow the seeds and cover slightly with the same compost, after which I give a good watering through a fine rose, and place the boxes in a vinery at work. I keep the soil always moist, and when syringing or bedewing the vinery they have their share.

After the seedlings have made their second pair of rough leaves I prick them out into other boxes, doing all the work in the vinery where they have been growing. I consider that it is by keeping them always moist that I am so successful, not losing one plant in the hundred. Gardeners err in keeping Stocks too dry.—G. Mc D., *Balclutha, Greenock*.

MY ORCHARD-HOUSE JOURNAL.

March 15th.—Dry, bright, and sunny, doors and ventilators all open; Peaches and Nectarines nearly in full bloom. The house is full of bees, yet there are no hives within half a mile, and but very few in the neighbourhood; they quickly load their thighs with pollen, and when they depart for home they seem much encumbered with their yellow balls. The diversity of blossoms in the different varieties of Peaches and Nectarines is most interesting, yet one seems to wish that all had the

nicely-shaped and brilliant-coloured large flowers of the Orange Nectarines and Grosse Mignonne Peaches, they are so very gay. It was pleasant to sit under the shade of the blossoms of a large standard spreading Peach tree, for there are no leaves, and the lively hum of the bees was so exhilarating that an hour or two passed quickly, the temperature 72°—perfection; and then, while looking at a host of seedling trees, one's eye caught a fine tree with large flowers marked, "From Coolidge's Favourite, crossed with the Stanwick Nectarine." The flowers of the Peach being small, and those of the seedling being large and beautiful, show that the cross has taken effect; in fact, the tree bore some fruit last year, which were noted as "large, delicious, with the true Stanwick flavour." Many other cross-bred seedlings show by their blossoms that the crossing has been effective.

March 16th.—The day cloudy, not a bee to be seen or heard. The early Cherries, such as Belle d'Orleans and Pigarreau Jaboulay, the earliest of the race, in full bloom.—T. R.

NEPETA NEPETOS (NEPETELLA?) AS A BEDDING PLANT.

THIS, like *Viola cornuta*, is an old border plant, but while one has been lauded the other is now never mentioned, yet of the two I think the *Nepeta* the more useful. No other plant of its colour can be used with such advantage in the flower garden. As an herbaceous plant it is pretty and graceful, and as a bedding plant it is equal to any. It will flower from the time of planting-out up to that of its being taken up in the autumn, no matter whether the days be rainy or bright, and when seen from a distance in conjunction with yellow *Caleolarias*, *Pelargoniums*, &c., it has a very pleasing effect, its habit being so different.

It is easy of propagation, and as easy to keep over winter, and if more of it were used we should not need to call out so much for a blue flower to come in for a third or a fourth line in our ribbon borders.

It requires a little clipping at the sides in summer to keep it from encroaching on its neighbours; but that is not more than the pinching and other attention required by a great many of our bedding plants.

Its treatment here is to strike cuttings in autumn in pans, keeping it over winter in any place from which frost is just excluded. It is potted early in the spring, placed in heat for a few days to root it quickly; is then hardened-off a little, placed out of doors, and finally planted about the middle of May.

So treated it is a most effective bedding plant, and of a colour greatly needed.—J. W. K.

THE MISTLETOE IN FRANCE.

I MUCH regret that owing to some unaccountable delay in the transmission abroad of some of the numbers of THE JOURNAL OF HORTICULTURE, I have only just been made aware of the inquiry which Mr. Robson had addressed to me on the 30th of January last. I lose no time in replying to it.

The Mistletoe is not found on the Oak in this part of France—in fact, it would be difficult for it to find a twig to grow upon, owing to the practice of cutting off all the branches of the trees for firewood.

The Poplars mentioned by M. Edouard André, which grow abundantly on the sides of the canals and rivers, and the cider Apple trees, are those it affects in the localities I have previously mentioned. It flourishes on nearly all the latter, young and old, healthy and unhealthy, on ground which has not been moved for years, as well as on that which was ploughed up or dug with the curious Breton spade, as it were but yesterday. The Apples are good of their kind and yield excellent cider, at least the Bretons seem to think so.

I cannot agree with M. Edouard André, that "everywhere in France this parasite is sought for and destroyed." Its only natural enemies seem to be the English sailors, who, when "Christmas is coming," may be seen with their wonted activity and daring, climbing the tall trees and robbing French orchards of their winter verdure, as, perhaps, in their boyish days they robbed English orchards of their autumn produce, more agreeable to schoolboy appetites. Except for purposes of exportation, I believe the Mistletoe would remain untouched for years.

"When western France shall be so carefully and indus-

triously cultivated as the home counties of England." When—when—will that be? In the depths of the remotest futurity lies the fulfilment of that anticipation. Judging, at least from the present state of agriculture, the hindrances to its advancement, the slow progress made, the friends of the dear old Mistletoe may take courage. If its extinction depend on a high state of cultivation, as it most probably does, many, many years must elapse before in Brittany, at least, it "will be lost to sight, and to memory, alone, dear."—A TRUE BRITON, *St. Malo, Brittany*.

ROYAL HORTICULTURAL SOCIETY.

FIRST SPRING SHOW.—March 14th.

Shows there have been, opening the exhibition season, both earlier and later in the spring than that held in the Conservatory arcades at South Kensington on Saturday last; but though some may have equalled it, many been favoured with finer weather, certainly there has been none to surpass it in the general excellence of the display. Hyacinths, Tulips, Crocuses, and Cyclamens were the principal subjects for which prizes were offered; but Roses, as beautiful and perfect as in the height of summer, along with Camellias, Azaleas, Rhododendrons, and forced shrubs of different kinds, increased the variety and enhanced the interest of the Show. The competition even, where the competitors were not numerous, was severe, and it was most pleasing to remark the greater number of exhibitors, and the improvement in the amateurs' classes. This alone would lead to the conclusion that the cultivation of spring-flowering bulbs is advancing, did not every window, every villa garden near London, bear evidence of the fact by the Hyacinths, the Tulips, and the Crocuses which are there displayed by the owner, and which afford quite as much gratification to the general public as to himself. On the road to London one gradually comes to take an interest in the window plants and gardens by the way, to note the success here, the failure there; the attention to the wants of the plant in the one case, the absence of it in the other; and to distinguish the real lover of gardening from those who keep plants merely from a feeling of ostentation.

Class 1 was for eighteen Hyacinths, and in this the competition for the first place lay as usual between Messrs. Cuthush, of Highgate, and Mr. William Paul, of Waltham Cross; both collections, it is scarcely necessary to remark, being of the highest excellence. Last year Mr. W. Paul took a long stride to the front, exhibiting spikes such as have never, we believe, been equalled, and which were as nearly perfection as could be conceived; but this year the opponents with whom he has had so many severe struggles proved victorious in a well-fought field, though in neither collection did we think the spikes so remarkable as last year. Messrs. Cuthush, whose spikes were most excellent, had of Blues, Marie, Baron Von Tuyl, Argus, and Grand Lilas; General Havelock, blackish purple with a metallic lustre; Haydn, a very fine mauve; of Reds, Von Schiller, Macanlay, Mrs. Beecher Stowe, Le Prophete, Florence Nightingale, Emmeline; Blush, Duke of Wellington, double, Gigantea, and Grandeur à Merveille; White, Snowball, Mont Blanc, and Mirandoline. Mr. W. Paul's eighteen was as follows:—Blues, Garrick, double; Charles Dickens, King of the Blues, Argus, and Lord Palmerston, purplish lilac with a white eye, and very effective; of the nearly black kinds, Fernck Khan and General Havelock; Reds, Garibaldi, brilliant dark crimson, Solfaterre, Von Schiller, Koh-i-Noor, Princess Helena, soft rose, Florence Nightingale; Blush, Gigantea, Seraphine, and Grandeur à Merveille; Snowball, white; and Ida, yellow. Mr. Cuthush, of Barnet, who was third, had very good examples of Charles Dickens, Fernck Khan, Duc de Malakoff, buff, Leonidas, Grand Lilas, Argus, and Marie.

In Class 2, for twelve Hyacinths of six kinds, the same three exhibitors competed as in Class 1, and took the same relative positions in the prize list. Messrs. Cuthush had very equally grown pairs of Baron Von Tuyl, Grand Lilas, General Havelock, Von Schiller, Macanlay, and Mont Blanc; and Mr. W. Paul had Garibaldi, Princess Mary of Cambridge, very pale blue, Snowball, Florence Nightingale, Koh-i-Noor, and Mont Blanc. These were also very fine examples of cultivation, and were arranged with great care to show a variety of colour. In the collection from Mr. Cuthush, of Barnet, the most noticeable were Haydn, Grand Lilas, and Mont Blanc. Mr. Macintosh, of Hammersmith, sent among others Victoria Alexandrina, bright red, very fine in colour, though the bells were small.

Class 3 was for six kinds, and for amateurs only. Here the first prize went to Mr. Steel, of Hammersmith, who had well-grown examples of Grandeur à Merveille, Charles Dickens, Robert Steiger, Grand Lilas, Gigantea, and Mont Blanc. Mr. Bartlett, also of Hammersmith, was second with a good six, consisting of Elfrida, Charles Dickens, Sultan's Favorite, Grand Lilas, Gigantea, and Queen of the Netherlands, white. Mr. Wilding, 2, Chesterfield Street, Enston Road, was third. Mr. Wiggins, gardener to W. Beck, Esq., of Isleworth, and Mr. James, North Road, Highgate, also sent good collections; and others came from Mr. Beech, gardener to C. J. Herries, Esq., Sevenoaks; Mr. Young, Mr. Hooker, Brompton; Mr. Burden, Mile End Road, Bow; and Mr. Higgs, gardener to Mrs. Barchard, Putney Heath.

Class 4 was for six kinds grown in pots in windows. Mr. James

was first with good examples of Garrick, Charles Dickens, Von Schiller, Macaulay, Mont Blanc, and Gigantea; Mr. Bartlett second, and Mr. Wilding and Mrs. R. Young, equal third. Mr. Steel, Mr. Turner, Portland Road, Notting Hill; Mr. Beech, Mr. Wiggins, and Mr. Barden were the other exhibitors.

Class 5 was for six Hyacinths, new kinds never before exhibited. The first prize in this was taken by Mr. W. Paul with *Clio*, bearing considerable resemblance to Lord Palmerston in colour, but with larger bells and broader in the segments; *Eclipse*, crimson, edged with rose, brighter in colour than Von Schiller; King of the Yellows, a great advance in its class, having a finely-formed compact spike, deeper in colour than *Ida*; Grand Monarch and Byron, in the style of Grand Lilas, with fine spikes and bells, and broad in the segments; and *Autocrat*, very dark purplish violet, fine spike. Messrs. Cutbush were second with *Vnlean*, almost black, loose spike; *Bijou Celeste*, white, good substance, broad segments; *Prince Alfred*, compact spike, good bells, glowing magenta crimson, shading off towards the edges; *Luna*, pale yellow; Von Siebold, dark blue, an improvement on Baron Von Tuyl in colour and form; and *Jesebo*, with a broad plum-coloured stripe along each segment, and a paler edge on each side.

In the next class, that for new kinds introduced since 1865, Mr. W. Paul was again first with *La Grandesse*, with a robust spike, white; *La Grande Ressemblance*, broad pale lilac bells tinged with blush; *Sir H. Havelock*; *Delicata*, double, pale blue, somewhat loose; *Mirandolin*, compact spike, small bells, rose striped with carmine, and having an orange tinge; and *L'Esperance*, dark blue with a purplish shade, fine. Messrs. Cutbush were second with *Goldfish*, yellow; *Prince Albert*, double, dark blue, close spike for a double variety; *Johnson*, good spike, purplish violet, with a light throat; *Arnold Prinsen*, much the same in colour as *Sir H. Havelock*; *La Mignonne*, double white; and *Sadowa*, with a dense spike of soft rose-coloured bells. In addition to his other fine exhibitions, Mr. W. Paul had in the miscellaneous class, a fine collection of about 120 pots of Hyacinths, and Mr. Bartlett one of eighty or ninety pots, in which were many excellent spikes.

Narcissi came next in the schedule. Mr. W. Paul was first with *Newton*, *Bazelman Major*, *Yellow Prince*, *Queen of the Yellows*, *Grand Monarque*, and *Gloriosa*; Messrs. Cutbush second with, among others, *Soleil d'Or*, showy yellow and orange; and *King of the Netherlands*, yellow and white. Mr. Cutbush, of Barnet, was third.

Of Tulips there was a good though not very large display, and with the exception of *Proserpine*, feathered and flamed yellow and bronzy rose, from Messrs. Cutbush, there was nothing very different in the varieties from those previously reported. Messrs. Cutbush were first with the above, *Fabiola*, *Proserpine*, *Vander Neer*, *Rubens*, and *Joost Van Vondel*; Mr. W. Paul, second, with *Keizerskroon*, crimson, broadly edged with yellow; *White Pottelbakker*; *Maas*, scarlet; *Proserpine*, *Vermilion Brilliant*, and *Moliere*. Mr. W. Paul also exhibited a splendid collection of Tulips, conspicuous among which were *Tourne-sol*, and *New Yellow Tourne-sol*, *Roi Pepin*, *Grootmeester Van Multha*, *Canary Bird*, and *Mianlus*, red and yellow. Mr. W. Cutbush, of Barnet, was third. In the amateurs' class, Mr. Steel was first; Mr. Bartlett, second.

Crocuses were unusually large and fine, both in the nurserymen's and the amateurs' classes. In the former Mr. W. Paul took the first prize; Messrs. Cutbush the second; and in the latter Mr. Bartlett and Mr. Steel held the same relative positions. The following varieties were very fine:—*White*: *Mammoth*, *Caroline Chisholm*, *Queen Victoria*, *Princess of Wales*. *Yellow*: *Golden Yellow*. *Purple* and *Blue*: *David Rizzio*, *Brunel*, *Perfection*, *Ne Plus Ultra*, *Prince Albert*, and *Lord Byron*. *Striped*: *Ida Pfeiffer*, *Princess Alexandra*, *Albion*, *Sir W. Scott*, and *La Majestense*.

Of Forced Shrubs only a few were shown, consisting of *Rhododendrons*, *Ghent* and other *Azaleas*, *Dentzia gracilis*, *Weigela rosea*, *Persian Lilac*, and one or two others. Mr. Willie, Oak Lodge, Kensington, was first; Mr. Earley, gardener to F. Pryor, Esq., Digs-well, second; and Mr. Steel, third.

Of Lily of the Valley, Mr. Howard, gardener to J. Brand, Esq., Balham, exhibited half a dozen potsful in beautiful condition, taking the first prize. Mr. W. Cutbush was second, with smaller potsful full of flower; and J. Brand, Esq., Balham, third. Mr. Salter, of Hammersmith, had the variety with beautifully striped leaves which is so ornamental, but it was not in full bloom. Good potsful of the ordinary kind were also shown by several other exhibitors.

In Cyclamens, Mr. Wiggins, gardener to W. Beck, Esq., made a most beautiful display with a collection of about 150 pots, and although the plants were not more than from sixteen to eighteen months old, some of the pots had not less than 140 or 150 blooms, and in one pot as many as two hundred had been counted, but in this case the corals were older. Mr. Wiggins well deserved the first prize which he obtained; the second went to Mr. Todman for a small collection of much smaller specimens.

Chinese Primulas of an excellent strain were shown in fine bloom both by Messrs. Dobson, of Isleworth, and Mr. Wiggins, who were first and second, and by Mr. Todman, who was third; also by Mr. Macintosh, of Hammersmith.

To the beautiful collection of Roses, from Messrs. Paul & Son, allusion has already been made. Among them were specimens in fine bloom of *Princess Mary of Cambridge*, *Alba Rosea*, *Gloire de Dijon*, *Madame Victor Verdier*, *Camille Bernardin*, *Madame Julie Daran*,

Lord Raglan, *Victor Verdier*, *Alfred Colomb*, *Marie Rady*, and *Manrice Bernardin*; but more remarkable even than the plants was the stand of a dozen cut blooms of *Marchal Niel*, some of which were upwards of 4 inches across, and all of them of the richest golden yellow. Not less beautiful was the companion stand of *Alba Rosea*, cream white with a delicate rose-coloured centre. In other boxes from the same firm were fine blooms of *John Hopper*, *Madame Victor Verdier*, *Virginal*, white and delicate pink, very pretty; *Xavier Olibo*, and others, and fine buds of *Madame Falcot*. Messrs. Lane, of Great Berkhamstead, likewise sent a numerous collection, mostly in small pots.

Foremost among miscellaneous subjects were the Camellias, of which Mr. W. Paul sent a numerous collection in small pots, and some, though in pots only 4½ inches in diameter, had four good-sized blooms. *Jubilee* was particularly fine. He also sent a very large specimen of *Donckelaari* in fine bloom, and a plant of *Eximia* of less size. Boxes of cut blooms were also shown by Messrs. Lee, of Hammersmith; Mr. Howard, of Balham; and Mr. Trussler, gardener to D. J. Kay, Esq., of Hoddesdon, who had *Donckelaari* very large and beautifully blotched and spotted with white. Mr. H. M. Kettlewell, Potter's Bar, contributed forced *Pelargoniums*, among which were *Belle Blanche*, a useful light variety, and *Monte Christo*; Mr. Laing, gardener to P. W. Flower, Esq., Tooting, tree *Mignonette*, about 5 feet high, with neat pyramidal tops; and Mr. W. Cutbush, Barnet, tree *Mignonette* trained on wire. Mr. Wilkie had a collection consisting of *Dracanas*, *Camellias*, *Epacris*, *Azaleas*, including two well-bloomed standards of *Iveryana* and *Criterion*, and *Hoteia japonica*, which has been frequently noticed as a very ornamental plant for spring decoration. Mr. Bull contributed *Bertelonias*, a fruiting *Aucuba*, *Camellias*, *Tricolor Pelargoniums*, *Cerasus Sieboldi rosea*, plena with large semi-double rosy lilac flowers, and *Glossodia major*, a terrestrial Orchid from Australia, having a purplish violet flower on the summit of a slender grass-like stem. Messrs. Lee had *Cyrtocentrum maculatum*, an old free-flowering winter Orchid, and *Odontoglossum Alexandrie*; and Mr. Burnett, gardener to W. Terry, Esq., Fulham, *Cologyne cristata* and *Dendrobium chrysotoxum*. *Neapolitan Violets*, very well grown and flowered, came from Mr. Roberts, Holmwood, Kent; and Mr. T. Ware, Hale Farm Nurseries, Tottenham, sent baskets of Alpine and spring-flowering plants. Mr. Earley showed two boxes of cut flowers, among which were *Acacias*, *Lilacs*, *Cinerarias*, *Azaleas*, *Thunbergia Harrisii*, and the lacework-like flower of, we believe, a *Snake Cucumber*, which would be lovely for bouquets, though not quite agreeably scented. Messrs. F. & A. Smith, of Dulwich, sent a collection of their fine new Variegated Zonal *Pelargoniums*, and Mr. Watson, of St. Alban's, baskets of *Miss Watson* and *Mrs. Dix*, two fine varieties, which he has frequently exhibited, together with a plant of *Annie Merry*, a promising sort with a well defined margin. Messrs. Paul & Son furnished a variety of *Dentzia crenata*, with pale green leaves prettily marbled with white, and *Dentzia gracilis variegata alba*, with the leaves variegated with yellowish white. Mr. Neale, gardener to P. A. Cartwright, Esq., exhibited a remarkably fine Smooth-leaved *Cayenne Pine Apple*, and Messrs. Lane an orchard-house *Plum tree*, which was between 4 and 5 feet high, and a mass of blossoms. For the above-named subjects several extra prizes were awarded, which will be found in the official prize list, published in another column.

Despite the unfavourable weather, there was a good attendance of visitors, among whom were their Royal Highnesses the Dukes of Cambridge and the Princess of Teck. We may also here call attention to the fact that the conservatory has at present a very gay appearance, the Camellias and several *Rhododendrons* being in fine bloom. Among the latter, *Rhododendron arboreum* is magnificent, and *R. nilagiricum* is covered with soft rose-coloured flowers.

FORTNIGHTLY MEETING.—March 17th.

FRUIT COMMITTEE.—G. F. Wilson, F.R.S., in the chair. On this occasion there was an unusually fine display of fruit, all of which was in admirable condition. Prizes were offered of 15s. and 10s. for the best and second best three dishes of dessert Apples. Mr. Tillery, of Welbeck, sent Cox's Orange Pippin, Rosemary Russet, and Mannington's Pearmain. Mr. Beach, St. Julien's, Sevenoaks, sent Blenheim Pippin, Winter Pearmain, or Duck's Bill of Sussex, and Ribston Pippin. Mr. Parsons, gardener to R. Attenborough, Esq., Acton Green, sent Braddick's Nonpareil, King of the Pippins, and Ribston Pippin. Mr. Cox, of Redleaf, sent Golden Harvey, Court of Wick, and Sam Young. Mr. Sidney Ford, of Leonardlee, Horsham, sent Ribston Pippin, Red Pearmain, and a variety erroneously called Scarlet Pearmain. He also sent a second collection, one dish of which was past and unfit for table, and was therefore disqualified. Mr. Whiting, of The Deepdene, sent Nickleham Pearmain, Cox's Orange Pearmain of delicious flavour, and Adam's Pearmain. Mr. Lynn, gardener to Lord Boston, sent Golden Knob, Sturmer Pippin, and Ribston Pippin. Mr. Dixon, gardener to Lady Holland, Holland House, sent Pile's Russet, misnamed Sam Young, Clunter Golden Pippin, and Royal Russet. Mr. Spivey, gardener, Hallingbury Place, Bishop Stortford, Greave's Pippin, Ribston Pippin, Cox's Golden Drop. On a very minute examination of all the dishes, it was decided that Mr. Whiting's collection was first, and Mr. Cox's second, and both were very fine samples in flavour, colour, and condition. In the competition for the best three dishes of kitchen Apples, Mr. Whiting sent Duncelov's

Seedling, Minchall Crab, and Alfriston. Mr. Cox, of Redleaf, sent Formosa Pippin, Dumelow's Seedling, and Scarlet Winter Pearmain, or Duck's Bill. Mr. Sidney Ford sent Sir William Gibbons, Royal Russet, and Norfolk Beefing. He also sent Flower of Kent, Wadhurst Pippin, and Beauty of Kent, misnamed Flower of Kent. Mr. Parsons, of Lyons, Sevenoaks, sent Hollandbury, Dumelow's Seedling, and Alfriston. Mr. Dixon sent Dumelow's Seedling, Yorkshire Greening, and Catshead. Mr. Lynn sent Dumelow's Seedling, Kentish Fillbasket, and French Crab. Mr. Spivey, of Hallingbury Place, sent Wadhurst Pippin, Kentish Fillbasket, and New Hawthornden. The first prize was awarded to Mr. Lynn, and the second to Mr. Whiting.

There was also a prize offered for the best dish of early Grapes. There was but one exhibition sent by Mr. Johnson, gardener to the Marquis of Aylesbury, Savernake Forest, and as they were very excellent and of good flavour, the first prize was awarded it. Mr. Whittaker, gardener to Lord Crewe, sent a bunch of Lady Downe's Grape which had been preserved by placing it in water containing charcoal, from which the air is excluded by sealing the cork. The bunch was somewhat shrivelled, and the flavour of the berries was watery, evidently caused by the absorption of the water in which the stalk was immersed, thereby diluting the saccharine juice stored up by the fruit. Mr. D. McKellar, of Colworth Gardens, Sharnbrook, Bedfordshire, sent a sample of Marguerite Strawberries, grown under the influence of Standen's manure, which were very fine specimens. Mr. S. Ford sent a fine collection of Apples, consisting of upwards of fifty dishes, and was awarded a special certificate. He likewise sent a dish of Uvedale's St. Germain Pear, under the name of Catillac, and one of Oranges. Mr. John Cadger, Luton Hoo Park, exhibited a Mushroom upwards of 7 inches in diameter, and which when gathered weighed 14 ozs. Though of large size, much larger specimens than this have been recorded. Mr. Dixon, gardener to Lady Holland, Holland House, exhibited two dishes of Mushrooms, seemingly excellent, but affected by a parasitic fungus.

FLORAL COMMITTEE.—Another very excellent exhibition of plants and flowers took place this day, and several certificates were awarded. Mr. Davies, Ormskirk, sent a neat dwarf-habited *Rhododendron* called *multiflorum*, with white flowers, a seedling from *R. virgatum*, and a second-class certificate was awarded it. Messrs. E. G. Henderson sent a basket of small plants of *Laminium maculatum aureum*, but they were too young for its merits to be decided upon; also a new *Cyperus*, *Lacouri*, a dwarf plant of very neat appearance—it received a second-class certificate. Messrs. Paul & Son, Cheshunt, exhibited an unusually fine collection of pot Roses in full flower. Rarely are such Roses seen at this early season. A special certificate was given them. From the same firm came three boxes of cut Roses, which were most lovely. There were several fine specimens of that gorgeous yellow Rose *Maréchal Niel*; a special certificate was awarded for them. Messrs. Veitch, who contributed largely to the show, had a very fine collection of Orchids, among them *Dendrobium crepidatum*, *Oncidium macranthum hastiferum*, and an extraordinarily fine specimen of *Cymbidium eburneum*, for which a special certificate was awarded. A special certificate was also given for the collection of Orchids. There were also some very nice plants of *Camellias* and *Azaleas*. A special certificate was awarded for the collection.

Mr. W. Paul sent small plants of *Deutzia gracilis variegata* and *Deutzia crenata marmorata*. Messrs. Smith, Dulwich, exhibited a collection of Variegated Zonal *Pelargoniums* of great merit. Among them were specimens of Sir J. Paxton, L'Empereur, Glory of Dulwich, Sultan, Marvellous, and Sunray. These were of the highly coloured Zonal section. Golden Circle, Gladiator, and Sybil, three of the Bronze Zonals, with a yellow ground, were extremely fine. A special certificate was awarded the collection. Mr. E. S. Williams sent a fine collection of Orchids. Among them an *Oncidium*, probably a variety of *O. obryzatum*, was awarded a second-class certificate. A special certificate was awarded for the collection of Orchids. Mr. Williams also sent a collection of *Cinerarias* and *Lilies* of the Valley, *Azalea Princess Helena*, and *Azalea Souvenir de Leon Mienhaut*.

Mr. W. Paul sent several new Hyacinths, which, although not producing such large spikes as usual, were of great merit. The following received first-class certificates:—King of the Yellows, Antocrat, very dark blue; Grand Monarch, pale silvery blue with shaded stripes; Clio, something of the same colour; Couronne des Bleus, pale delicate grey. J. Stone, gardener to J. Day, Esq., exhibited a fine specimen of *Oncidium Kramerianum*, resembling *O. papilio*. A first-class certificate was awarded it. Messrs. Osborn, Fulham, sent a very interesting collection of hardy spring flowers, consisting of *Scillas*, *Primulas*, *Ericas*, &c. A special certificate was awarded. Mr. Bragg, Slough, exhibited a large collection of Pansies, which were awarded a special certificate. W. Wilson Saunders, Esq., exhibited three or four Orchids, distinguished by their form or colour of flowers; one being *Zygopetalum crinitum*, of two varieties growing in the same pot, probably seedlings, one a remarkably fine flower with dark purple lip.

GENERAL MEETING.—W. Wilson Saunders, Esq., F.R.S., in the chair. After the election of thirteen new Fellows, and the announcement of several donations of plants and seeds, for which a vote of thanks was passed, the Chairmen of the Fruit and Floral Committees reported the awards of these bodies.

The Rev. Mr. Berkeley then said that on the last occasion he had directed attention to *Oncidium macranthum hastiferum*, of which at

the present meeting there was a specimen with eleven flowers from Messrs. Veitch, and one with five flowers came from Mr. Richards, Lord Lonsborough's gardener. Since the last meeting, Mr. Berkeley continued, he had been to Kew and examined Dr. Lindley's herbarium, in which he found several specimens of *macranthum*, which had been met with by a number of travellers in Peru, but none of *hastiferum*, though there was a pen-and-ink sketch of it by Reichenbach. He therefore could not say whether it was a distinct species or not. An unnamed *Oncidium*, shown by Mr. Williams, of Holloway, was then stated to be a mere variety of *Oncidium obryzatum*, which was also shown by the same exhibitor. *Zygopetalum crinitum*, exhibited by Mr. Wilson Saunders, was next referred to, as exhibiting two extremely distinct varieties in the same mass, one being much more handsome than the other. Whether this difference was the result of a sport, or arose from there being two distinct roots, he did not know. Mr. Berkeley then held up a spike of *Dendrobium*, of which the flowers were double; the divisions of the corolla were doubled, there were two columns, and two lips. This result he ascribed to lateral fusion. He next called attention to a matter of considerable importance in regard to two remarkable specimens of Mushrooms shown, and of which the gills were paler than he had ever seen before—a circumstance some might think was due to their having been grown in the dark and not developing their spores; but on close examination he had found that the gills were being gradually obliterated by a parasitic fungus. It became questionable, therefore, whether Mushrooms in this state were wholesome. For his own part he should not like to eat them, for, even if they were so, they had not that fine aroma which good Mushrooms ought to possess. No doubt the gentleman who sent the Mushrooms in question was not aware of their being in a diseased state; and when we hear, as we occasionally do, of deplorable cases of poisoning by Mushrooms, possibly such disasters may not be caused by the Mushrooms, but by the fungi with which they are attacked. With regard to the Grapes preserved by placing the stalk in water, it had been justly remarked that they were certainly not improved in quality. In the ordinary way of keeping, Grapes become something like raisins; but in this mode water was absorbed to the detriment of the flavour, and even with the addition of charcoal the water might get into a putrid state. The method was originally practised at Thomery, but it was universally acknowledged not to be a success. At the last meeting he had drawn attention to two kinds of decay, one being dry rot, the other a process of slow combustion. He had since been informed by a gentleman that he had specimens of wood which, if the latter process went on, might end in being pure carbon, and which, instead of being brown as with ulmates and humates, had become like anthracite. Mr. Berkeley then exhibited several specimens of wood attacked by fungi, and among others a drawing of one which had attacked teak at Madras, completely obliterating the medullary rays, and he said it frequently happened that these were completely destroyed in such attacks, while the longitudinal cells remained perfect. Wood was often affected by fungi, although there was no trace of their presence superficially. It might be asked of what interest was all this in a horticultural point of view; but he replied that it was of great importance to those about to put up houses. At Lord Fitzwilliam's a large range of houses had been put up with oak wood, which was in what was known as a "foxy" state—no specimen of such wood would be allowed in the dockyards—and the houses soon became very unsound. The reason of much of the wood in Northamptonshire being foxy was, that instead of being produced by trees raised from seed, very often old stools which were generally full of fungus were cut down, and the resulting wood became affected likewise. It was of great importance to ascertain before buildings were put up that the wood to be used was free from the mycelia of fungi. The next subject to which he would call attention was a model sent by C. Wykeham Martin, Esq., M.P., of Leeds Castle, Kent, showing a system of heating which was described by him in the first two parts of the Society's Journal (an account of this was given by Mr. Robson in THE JOURNAL OF HORTICULTURE, Vol. xi., pages 361 and 362). This mode of heating offered the advantages of but a small quantity of fuel being required to heat a large area; almost any kind of fuel might be used—Mr. Martin burnt faggots, and even sawdust; and it was extremely cheap, the expense of constructing the foundations and arrangements for heating a house 15 feet by 10 having been only £17 12s.

The Chairman said that those who were at the last meeting would recollect that a medal—the Lindley medal—was voted to Mr. Marshall for his exhibition of Cattleyas; but as it was a rule that members of the Council could not take such awards, though Mr. Marshall might have the honour of its being presented to him, he could not, in consequence of that rule, accept it. With regard to the *Zygopetalum crinitum*, referred to by Mr. Berkeley as exhibiting two kinds of inflorescence appearing to come from the same source, his impression was that two seeds had been dropped close together and sprung up. Now, if the same pod of seed produced the two conditions of the plant, he wished to know why we do not import seeds of Orchids instead of bulbs. The Cattleyas in Mr. Marshall's collection were all, he believed, the result of the seed of one species under different conditions, and it would be a great gain to horticulture in this country to import seed and raise plants from it, and in doing this he did not know that there would be any difficulty. Another subject taken up by Mr. Berkeley—dry rot—was of vast importance. He (the Chairman) had seen large portions of ships entirely destroyed by dry rot. Hundreds of thousands

of pounds were thus at stake, and many lives. With reference to teak, it was one of the most durable and finest of woods for ship-building, and how was it that dry rot attacked it? He believed that a great deal lay in the teak wood, when cut, not being properly seasoned and full of essential oil; but how dry rot could penetrate into the pores we did not know. We know that when a lot of timber is put together in an unseasoned state dry rot is sure to follow, and now in ship-building large air holes are left to prevent it; but so long as there is any dampness in timber, so long is there a tendency to dry rot.

Mr. Berkeley remarked that if any structure was made of unseasoned timber and painted when full of sap, it was sure to be attacked with dry rot. He would just add that *Dendrobium Bullerianum* is the same as *D. gratiosissimum*, which was published in *Botanische Zeitung* in 1855.

CARTER'S ASH-TOP FLUKE POTATO.

WE observe your correspondent, "D.s," remarks (page 182), respecting the above Potato, and have no doubt some of the many of our customers who have given it a trial will fully endorse the high character we have given it. We continue to receive the most encouraging reports of its excellence, whilst the rapidly increasing demand, notwithstanding the price being the same as last season, is to us the most substantial proof of its merits. Judging from your correspondent's general report, we should be inclined to surmise that his trial must have been under circumstances particularly unfavourable for Potato crops, as old kinds of established repute are condemned in common with the Ash-top Flake.—JAMES CARTER & CO.

NEW BOOKS.

A History of Variegated Zonal Pelargoniums, with Practical Hints for their Production, Propagation, and Cultivation.
By PETER GRIEVE.

THIS little volume contains all that is known about its subject, and as its author has been engaged in raising Variegated Pelargoniums ever since 1848, when Mr. Kinghorn produced *Flower of the Day*, he is entitled to the place of a first authority. He says—

"It was in 1853 or 1854, that my attention was first directed to this subject. By fertilising blooms of *Flower of the Day* with pollen taken from the well-known *Tom Thumb*, I succeeded in raising a variety which was named *Culford Beauty*. This was succeeded by several sorts of more or less merit, conspicuous amongst which was one called *Rainbow*, which proved the most vigorous, and possibly the best of the silver-variegated Zonals that had up to that time been introduced. This sort, however, fine as it was, was at last superseded by the more beautiful variety known as *Italia Unita*, which, up to the present time, is, perhaps, not surpassed by any other silver-edged variety.

"To return to the variety named *Rainbow*, this variety was of a somewhat remarkable origin. One of my seedlings of that period was produced by an old, dark-zoned variety called *Cottage Maid*, which had been fertilised by the pollen of Kinghorn's *Attraction*; and in the result, this one plant yielded me three distinct varieties—viz., *Rainbow*, a silver-variegated Zonal; *Empress of the French*, a marbled-stemmed variety, in the way of *Corse Unique*; and a dark-zoned, strong-growing sort, which was named *Emperor of the French*, and which, like its great prototype or namesake, appeared destined to play a very important part in the development of its race, inasmuch as it was instrumental in originating the now famous group of *Golden Variegated Zonal*, or *Golden Tricolor-leaved* varieties, which at that time had not been heard of, and, in fact, were not then in existence.

"About this time, 1855, it occurred to me that, considering the great advance that had been made in the way of improving the silver-margined varieties of the *Zonal Pelargonium*, something similar might possibly be effected with the golden-margined sorts, or rather sort, for at that period I believe *Golden Chain* was the only yellow-margined variety in existence. As to the date of the origin of this variety, there may possibly be some uncertainty; but that it is a sport from *Pelargonium inquinans* I think there can be little reason to doubt. In a very interesting paper communicated to the Royal Horticultural Society by Mr. Wills, of Houtroyde, the origin of this variety is put at about 1811. But I am inclined to think that it originated long previous to this date, for I have been informed that the late N. S. Hodson, Esq., of the Botanic Garden, Bury St. Edmunds, was in possession of a somewhat large and apparently old plant of this variety as early as the year 1822 or 1823. I can myself testify that about the year 1817 or 1818, the late Mr. D. Eaton had commenced to use it with excellent effect as a bedding plant, at Shrubland, near Ipswich.

"In the summer of 1855 I fertilised blooms of the old variety named *Cottage Maid* with pollen taken from *Golden Chain*, and the result of this cross was two distinct varieties, both of them improvements upon their pollen parent. They were named respectively *Golden Tom Thumb*, and *Golden Corse Unique*. During the following summer,

blooms of the *Emperor of the French* were fertilised by the pollen of *Golden Tom Thumb*, and this produced a variety which was named *Gold Pheasant*, a decided improvement upon its pollen parent, and inferior only to Mrs. Pollock, which last, together with *Sunset*, were the produce of the two following years, and were obtained between *Emperor of the French* and *Gold Pheasant*, making the latter the pollen parent. Again, using *Emperor of the French* and some similarly zoned seedling varieties as the seed-bearing parents, and using pollen taken from Mrs. Pollock and *Sunset*, the result was the production of the beautiful varieties named *Lucy Grieve*, Mrs. Benyon, *Lady Cullum*, &c."

Coleoptera Hesperidum, being an Enumeration of the Coleopterous Insects of the Cape Verde Archipelago. By T. VERNON WOLLASTON, &c. London: John Van Voorst.

THIS contains not merely an enumeration but a description of the species of *Coleoptera* of the Cape de Verde Islands.

ENTOMOLOGICAL SOCIETY'S MEETINGS.

THE second Meeting in February was held at Burlington House, the President, W. H. Bates, Esq., being in the chair.

Mr. MacLachlan exhibited a living specimen of the Stag Beetle, *Lucanus cervus*, together with the earthen cocoon in which it had recently been found, which also contained the cast-off skins of the larva and pupa states.

Mr. Ianson, on behalf of Mr. Latham, exhibited the nest of a social species of *Bombus* (*Anaphis reticulata*, Walker), from Natal, enclosing a great number of hard cocoons packed closely together, enveloped in a silky substance; also a number of the movable larva cases of a species of *Moth* allied to *Psyche*. Mr. Trimen stated that he had noticed the former nest to be very common in Port Natal, and that the perfect moth was yellow with four dark bars across the wings; the latter cases he had seen hanging by hundreds in *Acacia* trees in the same country.

Mr. Stainton read a few observations on the synonymy of *Tinea* (?) *alpicella* and *Zelleria Saviraga* (n. sp.), and *fascipennella*. Mr. Pascoe exhibited and described a curious new genus of *Cucujidae* from New Zealand, having only four joints in all the tarsi. An elaborate paper on the structure and homologies of the different parts of the ovipositor of female insects, especially in the order *Neuroptera*, was read by Mr. Eaton.

The President read a letter which he had received from Mr. Charles Darwin, requesting information from the members on the subject of the secondary sexual distinctions among insects, as well as upon sexual selection, and on the numerical proportion of individuals in the two sexes of various species of insects. Mr. Moore stated that males only of the *Tomius villosus*, a species which bores into and injures oak wood, had hitherto been seen. Of the curious *Tomius* dispar, the males of which are strikingly unlike the females, the latter were exceedingly rare. On the other, Mr. F. Smith stated that of *Tenthredo cingulata*, a species of Saw Fly common on Fern, the females might be taken by hundreds without a single male being seen; and of one of the Gall Flies he had reared thousands of specimens without having ever seen a male; and the male of *Eriocampa Abii*, another Saw Fly, was even still unknown. It was suggested, however, that the observation of insects in a state of nature was very difficult, and could scarcely be relied upon, as the habits of the different sexes of the same species were in many instances quite distinct, and that it was necessary, to ensure precision, that the species should be subjected to direct observation by being reared in captivity. Thus Mr. Stainton stated, that although in many species of minute moths the females were rarely to be seen at large, yet on being reared artificially there were at least 70 per cent. of that sex to 30 per cent. of males. Mr. MacLachlan stated also that of the curious *Forcas hymnalis* the females were sufficiently common, but that he had only seen four specimens of the male.

The March meeting was held on the 2nd inst., the President, H. W. Bates, Esq., in the chair. The President alluded to the lamented decease of Mr. Arnistead, a gentleman whose attention had long been directed to the study of the natural history of the various species of galls upon different kinds of plants.

Mr. Edward Saunders exhibited a number of species of *Euprestidae*, the nomenclature of which had been greatly confused, and which he had been enabled to unravel by the examination of the typical specimens in the Banksian collection, now in the possession of the British Museum which had served as the originals of the descriptions of many species by Fabricius.

Mr. Pascoe exhibited and read descriptions of an interesting new genus of *Prionidae* from Cape Coast Castle, and a new species of *Oxyecyrus* from South America. Mr. F. H. Wood exhibited several interesting chrysalids of *Sphingide* and nocturnal *Lepidoptera* from Sierra Leone. One of these, belonging to the *Bombycide*, of large size, was remarkable for having two deep excavations near the extremity of the body. He also stated that the long spiral tongue of *Sphinx Lignastri* is twice folded back within the tongue case of the chrysalis.

Mr. Stainton read a further communication from Mr. C. Darwin, requesting information relative to the numerical proportions of the sexes in insects, as well the effect of the brilliant colouring of the

under side of all the wings, or the upper side of the under wings alone in various Lepidoptera, considered as a secondary sexual character, instancing the Fritillary Butterflies, in which the under side of the wings is marked with silvery spots. The President, however, suggested that this peculiarity in these butterflies could not be regarded as connected with the sexual development, as the females were as much ornamented as the males. Mr. Weir stated that he had noticed a curious fact in connection with the brightly coloured under wings of the common *Triphena*, which seemed to indicate that this system of coloration was of no use to the insect in deceiving birds which invariably endeavoured to seize the moth by its very conspicuous hind wings on its attempting to escape by flight, many instances of the moth with torn hind wings having been observed by him. Mr. Stainton read letters from Mr. Henry Doubleday and the Rev. Mr. Hellins relative to the numerical proportion of the sexes in specimens of moths reared by them individually. The former of these gentlemen affirmed that

the males were decidedly more numerous than the females, and that in the whole of the Microlepidoptera he had never observed an instance in which the females preponderated; whilst Mr. Hellins as decidedly stated that there were more females than males produced in the majority of the species which he had reared; and Mr. F. Bond and Mr. MacLachlan stated that in the large Bombycidae, they had reared the two sexes in nearly equal numbers. It was important that the observation should be derived from reared specimens, as in a state of nature it often happened, from the different habits of the two sexes, that only specimens of one sex would be noticed by ordinary observers; as, for instance, in the common May Fly (*Ephemera vulgata*), it is only the males which unite in the beautiful dances in the air which every one must have observed. The President also called attention to a memoir just published by Dr. Kiesenwetter, in which he has applied the Darwinian theory to the development of distinct and permanent races in various species of insects, especially Chrysomelidae.

A RIBBON BORDER OF PELARGONIUMS AND VIOLA CORNUTA.

I DIFFER from your correspondent, "M. H., *Acklam Hall*," in the *Journal* of February 27th, anent a little favourite of mine, yclept *Viola cornuta* (I detect little difference between the rival queens of that ilk). *Viola cornuta* Purple Queen might be said to have swayed a regal sceptre last year over the accompanying little kingdom or queendom of *Flora*, and right royally did she discharge her office, albeit not clad in sheen of crim-

son or gold; not gaudy certainly; but with a quiet loveliness all her own did she entwine herself round the hearts of her beholders, her ermined companion, the tomentose *Cerastium*, acting well as a foil for her beauty. Very chaste indeed was the combination, lightened up by the bright yellow variegation of the circles of Cloth of Gold Pelargonium, and the brilliant shades of scarlet of the other circles.

1. *Viola cornuta* Purple Queen.
2. *Cerastium tomentosum*.

3. Cloth of Gold Pelargonium.
4. Imperial Crimson Pelargonium.

5. St. Fiacre Pelargonium.
6. Baron Nicasoli Pelargonium.

7. Cybister Pelargonium.
8. Lord Palmerston Pelargonium.

This chain border occupies the centre of a long strip of grass, bounded on one side by a shrubbery, and on the other by a terrace wall some 6 feet high, clothed with Roses, Jasmines, &c. On the top of this retaining wall, from the level of the terrace above rises an ornamental parapet wall of dressed open-work Bath stone 3 feet high. From this terrace and the end grassy platform a bird's-eye view of the border is obtained, the windings of the cable being distinctly traced, and the

general effect last year, planted as indicated above, was greatly admired. I daresay a better effect would have been produced had some good dark-foliaged and bright-coloured Pelargonium alternated time about with the Cloth of Gold; but the arrangement, though a show of uniformity was kept up, partook somewhat of our whilom Mentor, poor Beaton's pincushion beds, inasmuch as expediency dictated in a measure the materials employed.—W. HUDSON, *Chase Cliffe, Derby*.

BOILERS FOR HEATING BY HOT WATER.

At a recent meeting of the Leeds Professional Gardeners' Friendly Benefit Society, Mr. R. Featherstone, gardener, St. Ann's Villa, Burley, Leeds, read some notes on boilers used by himself or known by him for heating garden structures. We readily publish these notes, and would do the same gladly with any notes which a gardener would send us, relating facts on any horticultural subjects, whether in his own experience or observed by him in the practice of others. Such records of facts are among the best additions to knowledge.

"Where there are many houses, and a continued high temperature to maintain, no doubt the hot-water system is found far superior to the old flues. Granted, then, that to secure the best boiler suited to our purpose must be the first consideration.

"We have at St. Ann's Villa a kind called the Pocket Boiler, five of which are now heating fourteen houses very effectively; and believing that they are not in such general use as their merits deserve, I thought the accompanying sketch of one

FIG. 1.

a, Flow pipe; b, return pipe.

(fig. 1) would be of interest, as affording some means of comparison to others perhaps more extensively used.

"It will be seen that they are very simple in construction, and being all of cast iron are, therefore, very durable; also that they bear some resemblance to the old saddle boilers, but, perhaps, more to one I have seen advertised as the terminal saddle, and which I have no doubt is a very good boiler.

"A neighbour of mine (Mr. Wright), has had one of them put in place of a more complicated boiler, which failed after being in use only a very few years. After a few weeks' trial he speaks well of it, though I fancy one defect in it is the flaps or sides of the saddle not being deep enough to admit of its holding more fuel; and as the firebars are hollow and part of the boiler, the fireplace cannot be made larger by setting the boiler on a course or two of bricks, which is an advantage of the Pocket Boiler.

"I object to hollow firebars, as tending to prevent thorough combustion — a matter I hold to be nearly as important as utilising the heat; indeed, in our case, where we have to burn a low quality of fuel, consisting of cinders that fall through the bars of iron-puddling furnaces, it is of the first importance to ensure thorough combustion.

"About three years ago my employer, Mr. Butler, bought one of Clarke's Patent Water Jacket Boilers to heat the front hall, passages, &c.; but it fails entirely when it is attempted to burn the same quality of fuel as we burn in the garden. I attribute this to the hollow firebars and water jacket, as it is called.

"Our Secretary (Mr. Sunley), has in use one of Marriott's boilers, about which there were some inquiries a short time since in *THE JOURNAL OF HORTICULTURE*. He says that he is perfectly satisfied with it, and would not exchange it for any other kind of boiler.

"Other two neighbours of mine have boilers like fig. 2, with which they are both highly satisfied. For small places, to burn any quality of fuel, and to need little attention, I strongly commend them. Not the least of their recommendations are their low price, simplicity of construction, and durability.

"Another boiler which I have proved to be good is *Monro's Cannon*; but I scarcely think it will be found so durable as the *Pocket Boiler*. In short, after twenty years' experience with many kinds of boilers, I give my verdict in favour of the

Fig. 2.

a, Flow pipe; b, return pipe.

Pocket Boiler where there are numerous houses to heat. It would be better, on the score of saving labour, that instead of having five boilers there should be only two of twice or thrice the size of those we have; but, whatever kind and size of boiler be used, I urge the paramount necessity of using plenty of piping, the want of which the best boiler cannot compensate for."

NOTES AND GLEANINGS.

As a further step towards the advancement of the education of young gardeners, the Council of the *ROYAL HORTICULTURAL SOCIETY* have decided to commence forthwith a course of instruction in land-surveying, measuring, and ground work engineering to the students at Chiswick under a skilful engineer. They have also decided to open a class for instruction in drawing, which shall be open to all on the payment of a small fee. This class young gardeners residing within convenient distances of Chiswick, as well as the Chiswick students, will have the privilege of attending, and we trust that all who have the opportunity will avail themselves of the great advantages that such instruction affords them. All particulars relating to the drawing class may be obtained by applying to Mr. Richards, Assistant Secretary, South Kensington.

— On the 9th instant, at Margate, died Mr. EDWARD TUCKER. As a naturalist he was well skilled and liberal in imparting information; as a man he was kind and truthful. He first recognised the fungus causing what is emphatically called "the disease" of Grape Vines, and it is named after him *Oidium Tuckeri*.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Celery, the early sowing must be pricked out as soon as the seedlings have formed two rough leaves. The last of the *Cauliflower* plants should also be planted out from their winter quarters; and if any of the autumn-sown *Cabbages* remain in the seed beds plant them out, and fill up any blanks in the youngest rows. Where young *Cabbages* are in demand throughout the season, a few seeds should be sown every fortnight or three weeks until the end of June. *Corn Salad* or *Lamb's Lettuce*, sow now for a summer supply, either thinly broadcast in beds, or in lines about 1 foot apart, and cover lightly with fine soil. *Peas*, make a successional sowing of the *Champion* of England, *No Plus Ultra*, or any of the earliest wrinkled Marrow varieties; also of Johnson's Wonderful Long-pod *Beans*. When the plants of the early sowings of *Peas* are about 2 inches high, draw the soil neatly to them, and apply stakes of about the height to which the variety grows. Spruce fir or other evergreen branches will afford a useful shelter to early crops. As soon as the plants of the early crop of Broad *Beans* appear above ground the soil should be carefully ridged-up round them, and branches of evergreens stuck rather thickly on each side of the rows to protect them from frosty winds. *Salsify*, if a supply is wanted early in summer, sow a small quantity now, but for the main crop the end of April or beginning of May is early enough, for the plants sown earlier are apt to run to seed. *Skirret*, sow now, if the ground is in a fit

state for working, in lines 15 inches apart, covering the seed with the finest of the soil to the depth of an inch. Turnip, sow in a warm sheltered situation a small breadth of the Early Dutch for the chance of an early crop.

FRUIT GARDEN.

If the weather continues dry, and free from gales and sudden changes which generally occur about this time, the blossom of Peach and Apricot trees will stand much cold and yet set freely; coverings should be at hand to put over them in case of hard frost. Any trees or bushes transplanted this winter should not remain much longer without some mulching, if not already secured in this way.

FLOWER GARDEN.

Ply the broom and roller vigilantly, both on the lawns and walks, and, above all, cut the grass well into the "bottom" before the middle of next month, or you will be troubled with it throughout the season. Where rockwork is covered with plants it is one of the most difficult things in the garden to manage, so as to avoid destroying the plants on the one hand, or giving it a stiff formal character on the other. In regulating the plants avoid everything like formality; and while you keep each plant in due bounds, do not, if you can possibly avoid it, distort the symmetry of Nature. A little fresh peat or leaf mould may be added as a top-dressing to the more choice of the alpine plants, and a few seeds of trailing annuals may be sown in any vacant places. The boisterous winds of March are anything but congenial to florists' flowers, and the frosts that may be constantly expected must be guarded against with redoubled care, for every florist knows that more havoc is made amongst collections during the present month than at any period of the year. The *Auricula* is very susceptible of cold when expanding its blossoms, and should the temperature of the frame be too low, it is extremely difficult, and with some sorts wholly impossible, for them to bloom. When the nights are likely to be fine the frames ought to be left open so that the stock of *Carnations* may be hardened preparatory to their removal into blooming pots. Very few *Ranunculuses* ought now to be out of the ground. Seed may still be sown with success. Pinks appear to have been rather affected by the late winds. All cracks in the beds must be closed, and the plants looked over after frost and fastened. *Polyanthuses* are rapidly growing; care must be taken to trap snails and other insects injurious to the forthcoming blossoms.

GREENHOUSE AND CONSERVATORY.

The temptation to collect all plants in flower into the conservatory being great, you may be led into error by crowding them too much at this early season. Crowding plants in winter is a matter of necessity, and when the plants are in a dormant state this is of less consequence; but now that they are in active growth, unless they have room so as to allow of the admission of light and air amongst them, they soon spindle up out of all shape and proportion. Except in fine days little air is necessary for this house in March, and much might prove very injurious to tender flowers. *Camellia* blossoms are as soon affected as any by cold currents; damp the paths in the evening, and light gentle fires at night while the weather continues cold, and do not let the temperature fall below 40° for the season. The same routine of potting and propagating must be proceeded with in the greenhouse for some time yet, and the house must be kept damper and warmer. Syringe in the mornings, and damp the paths only in the evenings.

STOVE.

Propagation and potting will occupy the greater portion of the time here for the next six weeks. Attention must also now be directed to training and regulating the young growths of climbers and other free-growing plants. Newly-potted plants do not want much water until they are more established in the fresh soil. Bulbs of the *Amaryllis* tribe brought in for forcing may be potted, if they require it, when their leaves are half grown, but never pot them when they are at rest. The temperature here should now range from 60° to 65° in the morning, and air should be admitted as soon as the sun heat raises it to 70° or 75°. More frequent syringings and a moister atmosphere should now be kept up.

PROPAGATING PIT.

Dahlias and *Chrysanthemums* should now be propagated in order to produce stout early plants. Every young shoot of the *Gardenia* should be propagated. There is scarcely a sufficient number of them in any establishment. Any shelter that will do for *Fuchsias* will suit them in winter, and they force all the better if kept cool in winter. Bulbs of *Amaryllis* or other tribes brought in for forcing often make fine large leaves

but show no blossom, and on that account any out-of-the-way place is thought good enough for them afterwards; but the less these are disposed to bloom the more care is necessary to expose their leaves as much as possible to light, and to see that they have neither too much nor too little water, and that the pots are well drained. Turfy loam with a little leaf mould and sand suits a great many of these; peat is injurious to some of the more delicate sorts, whilst the most tender of the Iridaceæ will live only in light peat. Always keep up a moist growing heat of from 60° to 80° in these pits from this time, and fumigate them as soon and as often as the green fly appears, and avoid strong doses; better smoke often and give a little at a time.

PITS AND FRAMES.

Many of the established and more hardy plants in these structures may now be removed to temporary pits to make room for the spring-struck stock, now being daily potted-off. Do not permit any vacant space in the propagating frame until you have more plants than you require for bedding-out. It will be necessary to keep a genial heat in the cutting frame, and to top all cuttings that have taken root and are beginning to grow.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

The soil with us was too wet to permit of sowing seeds of the main crop of Onions, but sowed a few to keep on, also beds or rows of Lettuces, Radishes, and Spinach. We lately mentioned the efficacy of soot sown over the rows of Peas and Beans in keeping away mice and rats, but the soot not being renewed, after being washed by the rains, some rows had a number of vacancies in them, the Peas being cut over below ground just as they were coming well above it. A fresh dusting, and some tempting *poisoned baits* put in the way of the vermin, have rendered their visits since inconspicuous. This baiting when it can be done is more effectual than trapping. In wheeling away the dung from an old hotbed the other day, we found the remains of many huge rats that had died in their runs. Whatever material is used, the chief secret of success is never to touch the bait with the human hand. We generally mix all, and lay down securely where domestic animals, and even game, are not likely to go, using only a wooden spatula.

Moles.—These have been very troublesome of late, not only in the park but the lawn. One thing in favour of the steel and other traps is, that generally the mole when caught is killed at once. We were never great adepts at catching them, even when we used thick gloves to keep away the taint of the hand. One man who has taken it in hand, and been very successful, rubs the trap and part of the run with the skin of a dead mole.

General work has been much the same as in the previous fortnight, only we took thirty large pots, filled them with rough hay inside, except a small open space in the centre, and put them over *Sea-kale* in the open ground, after placing some ashes round the crown. As we may want to cover a good deal more placed a cone of ashes over the crowns, and a little litter, as this vegetable is not easily blanched white, if it once is allowed to become green. The packing of hay or of clean litter inside, prevents the shoots being over-heated, or cooled too much, and does away with any necessity for placing litter outside of the pots. Now is a good time to make fresh plantations. One-year seedlings do well, and if scarce, pieces of the roots 4 inches in length answer very tolerably, only they do not become so strong generally in one year. If to remain, the ground for this and Asparagus can scarcely be too well stirred, or too much enriched, if the manure used is sweet and decomposed, where it is near the roots. Rich surface dressings are eagerly enjoyed, and so is sowing the surface in summer, which also drives all slugs and snails to a distance, if it does not destroy them outright.

FRUIT GARDEN.

The chief work has been regulating Vines, thinning-out the superfluous shoots in the earliest house, allowing the next to come on gradually, thinning the shoots in the Peach house, giving all the air possible in the orchard house, and using a rough fan, made of a thin board with a handle, in calm days when there was a little sun. All brushing with camel-hair pencils, fanning, and shaking the trees, so as to assist in the dispersion of the pollen, is of but little use, unless the sun lends his aid. A few hours' sunshine in spring will next to secure a crop under glass. The pollen then becomes so light and easily diffused. We recollect, many years ago, having a Peach

house in bloom some weeks before Christmas, and although the bloom was fine, and seemed at first to set fairly, a great many of the young fruit dropped afterwards, long before the stoning period, and on cutting up scores of them, they were black at the heart, showing that though the germen had increased in size, fertilisation had never properly taken place. From the time of the bloom opening to its dropping the trees had not half an hour's sunshine if all the five minutes now and the five minutes then were added up together. A few hours' sunshine in a mild day, with a gentle breeze when the trees are in bloom, and the pollen boxes opening, almost makes sure of plenty of fruit setting. However, as it is always well to avoid reflections afterwards, the dispersing of the pollen by the modes adverted to may be resorted to. As giving data for comparison we may state that on this, the 14th of March, a few blooms are opening in the latest house, but the great bulk of the buds are strong and clustered together like strings of Peas. By all the air possible we will keep this house back, but the coming warmth will beat us, and our chief care at present is to see that the trees are not overdry, as that might cause them to drop their buds, and not to be flooded with water, as that, from the extra stimulus given, might be attended with a similar result. Hence when trees in such circumstances are in pots, it is always advisable to thoroughly moisten the soil—not at once, but at two or three waterings, with a couple or more days between them.

In the earliest house now in full bloom we give less air and shut up earlier, and when once the fruit is set we shall give air early in the morning, increasing if it wants it, and shut up and sprinkle early in the afternoon, taking advantage of the sun to do what forcing we there want. In this house the trees on the back wall were coming into bloom a week ago, and none of the buds were opening on the trees in pots in front in the border. As for several reasons we did not wish the pots to be much behind the walls, we curtailed the front air more, and that has helped them on. It has also caused two rows of Strawberries, placed near the front, to grow strongly. These houses since their washing in spring have not been touched with the syringe, and the trees will not be interfered with by watering overhead until the fruit is set. If very bright parching weather should set in, we will sprinkle the pathway and floor with the syringe to prevent the atmosphere becoming too parching. There has been no necessity for anything of the sort as yet, and Peaches when in bloom like the air to be rather dry, provided the moisture has not been dried out again by a sharp frosty east wind. Peaches and Nectarines also do very well if the house is shut up at night; but Plums, Cherries, and especially Apricots, should always have a circulation of air, however little the openings may be, until after they are fairly set. A little frosty air does little harm to them under glass so long as the blooms are dry. A close confined atmosphere, though not warm, will almost insure the dropping of the finest Apricot blooms, and also when just fresh set. Even when Plums and Cherries are to be forced they do best with a low temperature, and plenty of fresh air until safely set, and then they will stand a higher temperature gradually applied. As to Pears and Apples under glass, we have ripened them, and found the flavour, especially of Apples, very saccharine and delicious; but when much is done in this way it is the best plan to have the fruit set with plenty of air under glass, and then take the plants out in a dull day, and plunge the pots where water and mulching can be given to them. The slightest shade might be needed for a few days, especially if bright sun succeeded the dull day on which they were moved.

Melons.—Planted Melons in the box in which we raised and potted our spring Cucumbers, and left a number more to be planted out as soon as possible. As we cannot yet empty a pit full of cuttings striking, we gave the Melons left a larger pot to prevent their becoming stunted. We have frequently described our method of Melon culture, as to training, stopping, &c. We prefer single plants instead of turning out two or three plants from one pot. As saving labour and all trouble of future earthing-up, we may mention that in general we place the necessary quantity of soil in the bed at once. Our frames are so shallow, that to afford the foliage full room the soil is only an inch or so above the level of the bottom of the frame. This distance is kept all along, for as the dung bed sinks the frame sinks equally with it. In making the bed, therefore, the frame being 6 feet in width, a trench from 20 to 24 inches deep, and from 24 to 27 inches in width, is left in the centre, with a slab back and front, to confine the earth that is put in to this trench, with the exception of a

sprinkling over the dung at back and front. The soil in the trench thus soon becomes warm, but never so hot as to produce what is technically called burning, and yet the dung on each side preserves a mild genial heat a long time, and this amount of soil we have found sufficient for the generality of fair-sized Melons, and there is no trouble and no checks from future earthings-up. We use soil much stiffer for Melons than for Cucumbers, and in the case of the former we tread the soil firm before or after planting. When we grow Cucumbers early in frames we adopt much the same system of giving only a limited amount of earth for the roots; but in their case, if kept long in bearing, we top-dress with rich compost several times during the season. We were first induced to limit the soil by growing Cucumbers very successfully in pots and boxes.

ORNAMENTAL DEPARTMENT.

First Sowing of Seeds.—"A." cannot see the reason why we wish the ground to be dry and aired before we sow main crops out of doors, with the directions for draining, filling, pressing, and watering the soil in pots before we sow in them, to be placed under glass, or in a hotbed; and one other thing puzzles him very much, that one pot will scarcely yield a plant, whilst another pot sown at the same time from the same packet will come thickly all over, though the one pot had as much seed given to it as the other. In the first place, we like a rather dry bed for our seeds out of doors, because stiff soils, when moist, are so apt to crust the seeds, as to seal them up from the action of the atmosphere, and then no germination would take place. Again, sowing when the ground is wet, is apt to "poteh," and batter the soil, and it will take nearly a season before it again becomes so that the rains will pass easily and freely through it; and, lastly, because sowing when the surface is pulverised and dry, though giving the seed at once a good bed, makes sure it will have moisture enough from the damp beneath the seed, and which will rise all the more freely the more the sun acts on the surface.

The same principle is acted on and advised, when sowing particular seeds in pots. The drainage and the rougher soil below, and the finer soil above, will secure perviousness to air and moisture, and the previous watering secures moisture to cause the seeds to swell; the dusting with drier soil before sowing gives the seed a good bed, and the covering makes all secure, and then the shading will cause little watering to be needed before the seedlings appear. The reason for all this is twofold. Some seeds are very impatient of much water as they germinate, and immediately afterwards. If these seed pots are plunged beyond keeping the surface rather moist, much watering will not be required, and thus one element of safety is secured. Then many seeds are very tender, just when they are on the point of becoming plants, and having come to this state, even though not appearing above the soil in the pot, they are very apt to shrivel-up with dryness. Of course this should not be allowed; but who is so perfect as to attend to all things, and if a few pots should be missed, the well-drained moist soil beneath the seeds will act as a safeguard in securing just the requisite moisture. At any rate, with a powerful microscope we have found in seed pots in which stems were never produced, plenty of seeds, that showed they had been arrested after germination, by the shrivelled-up rootlets. So much for the reasons for the mode of preparing seed pots recently given.

As to Cuttings.—"B." wishes to know what is the use of silver sand placed on the surface of a cutting pot, and wants to know if other sand would not answer as well. The chief use of sand mixed with the soil in a cutting pot is to give free egress to the little rootlets, and equalise in the best manner, after drainage, &c., the requisite moisture. Its use on the surface of the pot is to keep the base of the cutting firm, and also to keep that part especially from being exhausted by evaporation into the atmosphere of the place. For very tender small cuttings, either a bell-glass or a little frame will be needed in addition to the glass roof, to prevent the cutting becoming exhausted by the free transpiration. Hence, for many cuttings, such as Heaths, this silver sand is a great advantage, and for general purposes it is also the best, as it is the purest; but for commoner purposes, pit, river, and road-drift sand may be largely used, and that will be the best that has least earth or other impurities. Almost all common sands may be improved by washing. When it can be had silver sand, the best, should be carefully used.

Another correspondent and his neighbour, amateur beginners, cannot see how it is possible to take a cutting from a growing plant, and yet keep the cutting growing, and so that it will scarcely show the lopping to which it has been sub-

jected. Well, we would rather not boast of the possibility of doing so, we will be perfectly satisfied if our random remarks shall show these and our other readers that the result would be at least a desirable consummation, and one which would set adrift the too common practice of letting cuttings wither and fall down, and then go to much trouble to make them stand upright again before they they can do anything to make plants of themselves. Be assured much will be gained if the cutting never shows the lopping-off from its mother plant. This can be managed even with tender plants by reducing the foliage a little so as to lessen the transpiring surface, and covering with a bell-glass, and shading in sunshine, so as to force the cutting to absorb as well as perspire. In the case of such plants as Verbenas, Lobelias, Calceolarias, &c., at this season hundreds and thousands may be struck in a moderate hotbed without any bell-glasses, with nothing but the sash of the frame, and yet never show a flagged leaf, and if 18 or 24 inches from the glass will rarely require the least shading. Of course such cuttings will not strike in half the time they would do in a strong heat under bell and other glasses, in addition to the glass roof of the place in which they are growing; but they will be sturdier, and require less time to harden-off so as to stand in the open air at last.

One remark more. Shading will prevent the flagging of a cutting, because it will lessen the evaporation of its juices; but bear in mind that shading prevents rooting, and the more you give of it, the more will the cutting be drawn out, lengthened upwards, without forming roots in proportion at the other extremity. Never, therefore, let shading remain longer than it is absolutely necessary. In many cases where the cuttings are exposed to the atmosphere of the place, and a fair distance from the glass, we prefer in sunshine gently to dew or sprinklo with a syringe their foliage, instead of giving them shade, because the shading is so apt to be left on too long.—R. F.

COVENT GARDEN MARKET.—MARCH 18.

The demand is slow, and does not keep pace with the supply, for in many articles we are overstocked. Cucumbers are abundant for the time of year. Heavy consignments of foreign goods, as well as from the Channel Islands, have again come to hand this week, comprising Asparagus, Broccoli, Artichokes, Salads, and Green Peas.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

LYCHNIS.—Miss King's note was forwarded to the writer of the communication.

LOCAL FLOWER SHOWS (Alpha).—We cannot afford space for reports of any except the most extensive of the country shows. There are several hundred of such exhibitions.

ALLOTMENT GARDENS (J. H.).—We know of no rules required except that the tenants shall pay their rents regularly, and keep their plots free from weeds. If you call at our office as you propose, there is a pamphlet awaiting you. We recommend you to look at "Allotment Farming," which is only 3d. in price.

WHITEWASH (S. P.).—To prevent its rubbing off dissolve plasterers' size in the water. A little washwoman's stone blue added imparts a good tone to the white and improves the appearance of the interior of a greenhouse.

FLOWER SEEDS.—"J. H." wishes to know where he can obtain seeds of the following plants:—*Tussilago petasites*, *Salvia nemorosa* (of Sir James Smith), *Origanum humile*, *Origanum rubescens* (of Haworth), *Cuscuta sinensis*, *Andropogon populifolium*, *Nepeta Mussinii*, and *Phacelia tanacetifolia*.

VERBENAS OF DISTINCT COLOURS (F. J.).—*Purple*.—Purple King and Admiral of the Blue. The latter is a bluish purple with a white eye. *Scarlet*.—Firefly, and a very dwarf-growing scarlet is *Melindere splendens*. *White*.—Le Grand Bonlie de Neige and Snowball. *Rose*.—Etoile des Roses, Crimson, and Crimson King.

WOOD TRELLIS (Idem).—It is quite unnecessary to have the laths placed across each other obliquely so as to form oblong lozenges as by your second plan, and we do not approve of your first plan by which they are placed vertically. We would have them horizontal. The latter will do 6 inches apart; that is a very good distance for the plants you name.

OTAHUTE ORANGE LEAFLESS (A Constant Subscriber).—These Oranges generally produce flowers and fruit very abundantly and but little foliage. This is mainly due to the plants being allowed to carry all the fruit that sets, and we have seen a score of fruit upon a plant, for which half a dozen would have been enough. We would thin the flowers, reduce the fruit when it is set, and give the plants the benefit of a moist and rather warm greenhouse so as to encourage free growth. A temperature of from 50° to 55° at night, and from 65° to 70° by day will, no doubt, give you growth, and, of course, better foliage.

TEMPERATURE FOR PLANTS (Idem).—*Pteroma elegans* and *Statice Bolfordi* are warm greenhouse plants. You would see what Mr. Douglas stated with respect to their cultivation in page 182. *Gesnera cinnabarina* and *Hibbertia* are stove plants and cannot be grown in a greenhouse. They are of easy culture. Some excellent hints on the management of *Gesnera cinnabarina* were given in page 149 of the Journal for February 20th.

SEEDS OF NEW ZEALAND PLANTS (O. W. P.).—We do not know the native names of New Zealand plants, and cannot, therefore, assist you.

CORNEA CULTURE (Idem).—You do not say what size your plants are; we will, therefore, take for granted that they are young plants and in small pots. They must now be potted (unless they are in flower), in pots 2 inches wider than those they are now in, using a compost of two-thirds sandy fibrous peat and one-third loam from rotted turves old and mellow, and silver sand equal to about one-sixth of the whole may be added, and a like proportion of bits of charcoal or small crocks, which will keep the soil porous. The fresh pots should be thoroughly clean inside and outside, and good drainage should be provided by placing potsherds at the bottom, and to the extent of one-fourth the depth of the pot, and upon these may be placed a thin layer of moss or turfy peat. The plant being turned out of the pot, remove the old drainage and any loose soil that comes away easily, but do not disturb the ball beyond loosening the outside a little with a pointed piece of wood; place enough soil in the pot to raise the collar of the plant within half an inch of the rim; introduce the plant in the centre of the pot, fill up around the ball with the compost, making it rather firm about the old ball, give a good watering through a fine-rosed watering pot, and place the pots in the warmest part of the greenhouse, but near the glass. A temperature of 45° at night and 55° by day from fire heat will be sufficiently warm. The plants should not be allowed to suffer from want of water; indeed, after the roots are working freely in the fresh soil they should be well watered, and a gentle syringing overhead morning and evening will be more advantageous than too much water at the roots until they recover from the potting. The soil must not be saturated with water, nor should it long remain dry, and it must never become so dry as to affect the foliage. They may be kept rather close for ten days or a fortnight after potting, and a slight shade may be given from bright sun in the early part of the day; but when they become established they cannot have too much light and air, but avoid cold drying currents. Abundance of air and close proximity to the glass are necessary to secure compact growth. By June the plants will have filled the pots with roots, and when that is the case they may be potted in 8-inch pots; but not unless they have made good growth and filled the pots with roots. The same compost as that previously used may be employed, and a good watering given. After potting place the plants in a cold frame or pit if at hand (if not return them to their old quarters), and keep close and shaded from bright sun for ten days, but admit a little air every morning and shut up early in the afternoon, giving a gentle syringing morning and evening, but avoid anything like heavy waterings until the plants are fairly established in their fresh pots, when a more liberal supply of water will be necessary. It should, however, be given with care, and air should be admitted freely. In warm weather the lights may be drawn down at night, and drawn on in the morning, tilting them high at back, and if very dry hot weather a slight shade from hot sun will be beneficial. The growth being now vigorous, any straggling side shoots should be cut or pinched back and a close pyramid formed. This should not be practised after the middle of July. In August the growth will be complete; the plants may then be fully exposed night and day except when the weather is very dry and hot, then a slight shade will be very beneficial, and during heavy rains the lights may be drawn over the plants but tilted at the back. In October the plants should be removed to the greenhouse, be placed near the glass, and in a position which is not shaded, affording them an abundance of air, and to keep them from becoming one-sided the pots should be turned halfway round occasionally. Avoid cold draughts of air, give water rather sparingly and very carefully in dull, damp weather, and, as a rule, water will not be required more than once a week in winter, but the soil must be kept moist, and when the plants are in flower a liberal supply will be necessary. After flowering in spring place in a cool situation for a fortnight or three weeks, then cut them in rather closely, shortening back all the straggling shoots, and set the plants in a rather close and moist atmosphere. When the fresh shoots are an inch long repot, giving a liberal

shift, the same compost being used, and the same course pursued as in the previous year. If the plants are old they may be slightly disrooted every year, and repotted in the same size of pot. Correas are rather subject to red spider, but it may be kept under by a free use of the syringe, and they are sometimes attacked by scale owing to their being kept too warm. Exposure in summer is the best remedy for it.

PLUMBAGO STARTING (A. L.).—The plant of *Plumbago capensis* should now be pruned and started into growth, and when it has made shoots a few inches long it should be repotted. The *Stephanotis floribunda* should not be started until the beginning of May; and the *Bougainvillea spectabilis* should be retarded and kept in a cool house until the beginning of June, but we very much question your having it in flower at the time named—the middle of July.

STRIKING CUTTINGS OVER A FLUE (A Subscriber).—We fear your chance of striking cuttings by placing them upon the greenhouse flue is very small, as the heat will be so fluctuating. We would advise your placing a flagstone or thick slates upon the flue, and have a box made about 3 feet long and from 18 inches to 2 feet wide, according to the width of the flag or slate bottom placed on the flue. The box may be 15 inches deep at back and 1 foot in front, and should have a glazed frame or light covering it. The light may be hinged to the box at back, or it may slide; it is always best to have it moveable. You may then place the box upon the flag, place 3 inches of coarse gravel at the bottom, and then from 4 to 6 inches of sawdust or other loose plunging material, in which you can plunge the pots containing the cuttings. The light being put on, you may secure a moist and close atmosphere. A thermometer placed inside you may rise to 60° or 70°, which will be sufficient heat for the cuttings you name; indeed they will strike well if you cannot command more heat than from 50° to 55° at night. Any excess of heat or moisture may be disposed of by raising the light. Shade will be required from bright sun.

FUMIGATING WITH TOBACCO (Idem).—For a house the size you name half a pound of tobacco paper will be sufficient. Your best mode of fumigation will be to take a flower pot, make the hole rather large, and place two pieces of wood on the floor or on a slate in front of the house, so that the pot will stand upon them and air pass under the pot, the hole being left free. If the tobacco paper is rather dry half of it should be made damp, but if it is all wet half of it must be made rather dry. It should be torn in pieces about the size of half a crown, and the damp and rather dry be kept separate. Choose a calm evening, and, having the foliage of the plants dry, shut the house up closely, and place a few lumps of charcoal in the fire, and when they become red hot put them at the bottom of the flower pot. Two or three lumps about the size of a walnut will be sufficient of lighted charcoal to place in the pot, which without delay should be set upon the pieces of wood; and upon the charcoal should be put the rather dry tobacco paper, placing it lightly over the charcoal. When it commences to smoke put on more of the rather dry paper, and then the damp tobacco paper. You may repeat the fumigation the next night but one, and again in a week. We think this will destroy the green aphids.

ODOUR FROM LIQUID MANURE (S. S.).—We would not recommend the disinfecting of the liquid manure, for the odour of which you complain is quite as stimulating to the leaves as the liquid is to the roots of the plants. Liquid from sheep's droppings is more powerful than that of cows, but is not so unpleasant, and it does not clog the watering cans. Only place a peck in a tub, and pour over it thirty gallons of water, and stir well up and frequently until dissolved. For a greenhouse, in consequence of the smell of liquid manure being objected to, we have employed soot water made by pouring thirty gallons of water over a peck of soot, stirring well up, and letting the liquid stand for forty-eight hours, and then stirring again previous to use. We do not say this is equal to liquid from sheep droppings, but it is a good liquid manure. We have added thirty gallons of water and one peck of sheep droppings to the soot water above named; or put one peck of soot and one peck of sheep's droppings to sixty gallons of water, and have not had any complaints of the smell.

LIQUID MANURE (Newcastle).—The liquid from night soil is a very powerful manure, and is good for all the plants you name, but should be diluted with not less than six times its bulk of water when applied to plants, and for ground where seeds are to be sown it may be poured on undiluted some time previous to sowing the seeds. Night soil mixed with an equal quantity of dry soil is very beneficial to a kitchen garden, and a very valuable addition to the manure heap.

SOWING GRASS SEEDS (Idem).—Early in April is the best time to sow grass seeds. We would spread a little fine rich soil over the ground previous to sowing, and scratch it well with an iron rake. 2 lbs. lawn grass seeds will be sufficient for the extent of ground you mention. After sowing roll well; or, if you have not a roller, beat well with the spade, taking care that the soil does not clog to the spade. The seeds are best sown when the ground is dry.

CUCUMBER BED MAKING (Idem).—We think the time you name would be very suitable, as you need not then make so high a bed; one 3 feet high will be quite sufficient to make in the middle of April. Horse dung is certainly best for hotbeds; but we have used straw cow dung successfully, and should prefer it if you could obtain it for late hotbeds, as it does not heat so violently as horse dung. If you use horse dung—which we should in your case prefer, as it will be the best for your soil when done with for hotbeds—take care that it is turned over once or twice before being used, in order to secure a milder heat and its parting with the rank steam. If very dry, water should be thrown over it at each turning. It should be made regularly moist throughout, to give a good enduring heat.

TREATING GROUND FOR ONIONS (G. P.).—It is indispensable for a crop of Onions that the ground be firm, and especially in the case of light soils. It cannot be made too firm, but avoid making it so when it is wet. Your other question was answered in the Journal of March 5th, page 191.

PIMELEA HENDERSONI COMPOST (E.).—For the plants you name, in addition to that now mentioned, the following compost will grow them well—namely, two-thirds sandy fibrous peat, one-third well-reduced loam, from rotted turves torn in pieces with the hand, rubbed, and made fine, but not sifted, one-sixth silver sand, and a similar quantity of pieces of charcoal from the size of a pea up to that of small hazel nut, the whole well mixed. Good drainage must be provided.

WATERING LAPAGERIA ROSEA (Q. G.).—Your plant will require water every day when it is in free growth, and may have a three-gallon watering

poiful of water at each watering. The soil must be very well drained. You should not cut off any of the stems, but let all grow. We imagine the plant is a large one, if not, half the quantity will suffice; and, if newly planted, every other day will be sufficient watering until the roots are working freely in the border.

VIOLA CORNUTA NOT FLOWERING (S. S.).—We fear you have not the true variety. It is so very free-blooming that we could hardly credit its not blooming, had we not had similar instances. In one case we had it from seed, and the plants produced but few flowers for a year or two; but after they were propagated by cuttings or division of the old flowerless plants we had an abundant bloom. Having the true variety, you cannot grow it without having a mass of bloom; but we find that sometimes it does not flower very freely, particularly after a period of drought. Old plants do well for early summer-flowering, but for summer and autumn young plants from cuttings in autumn or division in spring are best. We would advise your trying plants from cuttings or division. If your soil is light, water well during dry weather. *Phacelia tanacetifolia* may be had of most nurserymen.

STRAWBERRY FORCING (Roland Quis).—In ordinary seasons the Strawberries would ripen in the frames by the second week in June. If to be fruited in a Strawberry house we would move them into it in the first week in May.

MUSHROOMS (W. S.).—We should judge by your description that the Mushrooms from the lawn are wholesome. Owing to the snow during the severest frost, we would not be surprised if Mushrooms came early out of doors this season. We should have been surer of the Mushrooms had you sent us a specimen.

SETTING THE BLOSSOM OF ORCHARD HOUSE PLUM TREES (C. P.).—In weather in which plenty of air can be admitted, we do not consider it necessary to use a camel-hair brush for either Plums or Peaches in our orchard house. As you have used it to the latter, all well, and if the weather is dull and sultry use a fan, or a thin flat board waved backwards and forwards among the trees; but with abundance of air, a fair amount of sunshine, and a gentle breeze, even this may be dispensed with.

TEMPORARY PROTECTION FOR BEDDING PLANTS (W. R. C.).—In ordinary weather your old druggist will be sufficient to protect the bedding plants in the box 9 feet by 6 feet, and 18 inches deep. In severe weather a little more may be required. The worst of the druggist is, that in a very cold or very wet day your plants would receive little light with the druggist on. We would prefer calico strained tightly. We have used calico, glazed when bought; we have used it rendered more transparent with oil and driers; but the result of our experience is, that it is best to use a cheap thin calico, unbleached, fix it on a pole at each end, and stretch it tightly by strings back and front. This we leave on night and day, until within a week or two of planting-out time. In your 9-feet length you would, in addition to the two ends, require three rods at equal distances crosswise in the centre, to keep the calico from drooping down to the plants. Your druggist would be useful in March, at any rate over the calico at night. 3½ yards, 2 yards wide, would do for your place. We will cover our cutting beds for some time yet with mats. In fact, for all hotbeds we generally cover until June.

POTATO SETS (Thunderbolt).—Drying the sets, but not so as to shrivel them, is a very good plan. If the place where they are grown is warm enough to induce them to sprout, all the better. Do not rub off the sprouts, but plant with the sprouts upwards. Such treatment promotes the early ripening of the crop, which is the best mode of avoiding the disease.

ACUCUA BERRIES GATHERING AND SOWING (F. J.).—The proper time to gather *Acucua* berries is when they part freely from the plant after having become quite red, and remained in that state on the plant for some weeks. They may remain on the plant for ornament until they begin to shrivel, when they will either fall or may be removed. Now is a good time to gather and sow the berries. Sow in light soil, and place the pot or pan in the greenhouse or in a mild hotbed. The vase, from what we have seen of it, is very strong; it is sold by Messrs. Hunt & Pickering, of Leicester.

FIXING CANVAS TO PROTECT WAIL FRUIT TREES (J. N. P.).—The way we fix our netting for protecting fruit trees is very simple. We have some larch poles sawn up into battens 2 inches square, and of such a length that they will reach from the ground to the under side of the coping, and be 1 foot longer than that—namely, for a wall 12 feet high the poles are 13 feet long. Holes are made in the ground 2 feet from the wall, and the pole introduced, the upper end immediately under the coping, and the other in the ground, making it fast by filling in with soil. The poles are fixed 3 feet apart, and all on the same slope, the foot of the poles being 2 feet from the wall at the ground. Small brass or galvanised iron rings are then sewn on the netting at top, the first at the end, and others at 18 inches apart along the upper edge. Galvanised hooks are driven into all the poles at top, and midway between each in the wall, small gas-pipe hooks being excellent. The rings are placed on the hooks, and the netting or canvas let fall. Two or three rings will be required at each end, and hooks in the wall to secure the covering to. If the covering reach to within 18 inches of the ground that will be sufficient. At every pole a ring should be sewn on the canvas, and a hook driven in every post, and so low that when the rings are placed over the hooks the covering will be drawn tight. The covering will be secure against wind, and be kept at such a distance by the poles as to prevent injury to the blossom. In uncovering the trees we first of all place a number of bricks upon the top of the wall, one at every 6 feet. After breakfast, if there has been frost during the night, and if there has been no frost, before breakfast, the rings are slipped off the hook along the bottom, and at the ends as far as can be reached. This done, we get upon the wall, and commence folding or rather rolling the covering up, and it is placed upon the wall, and bricks above it to prevent its being blown off. The covering is let down at night, and secured to the hooks, the whole being but the work of a few minutes to an active person. On frosty days the netting is not taken up.

ANTS ON A LAWN (Miss Harvey).—The best remedy is to place on it a hen with a brood of partridges, putting the hen in a coop close to a bush on the lawn. A brood of pheasants, or even chickens with the hen, near the spot will do much to keep down ants. If you do not like this you may sprinkle guano over their haunts, and it will drive the ants away. Ammoniacal liquor from the gasworks will also drive them away.

WIREWORMS IN CUCUMBER COMPOST (E. S. Y.).—We would advise you to scatter soot over the compost, commencing at one end to turn it, and sprinkling the soot over the compost as it is being turned. In addition to this we would make the holes 3 inches deep all over the bed, at about 6 inches apart, and drop in each one-fourth of a raw Potato. You may examine these twice a week, and you will no doubt find the enemy, and may then destroy it. The Potato baits will certainly keep the wireworms from the Cucumber plants.

ASPARAGUS FROM SEED (J. M. Dublin).—You may obtain as good beds of Asparagus by sowing the seed, and thinning the plants out to a proper distance, as if you were to put in plants. It is not necessary to transplant the seedlings; they will answer well left where sown for the permanent crops or beds.

PLANTS FOR SUSPENDED BASKETS (O. C. G.).—Pretty plants for suspended baskets in a vinery are *Alyssum variegatum*, *Nierembergia gracilis*, *Tradescantia zebrina argentea*, *Rhodochiton volubile*, *Thunbergia alata*, *Convolvulus mauritanicus*, *Lithospermum fruticosum*, *Saxifraga sarmentosa*, *S. Fortunei variegata*, *Lobelia Gordoniana*, *L. speciosa*, *L. faxoniana*, *ivy-leaved Pelargonium*, *Pelunias*, and *Heliotropes*. These will do well for greenhouse or cool vinery. For a heated or warm vinery we would have of Ferns (the preceding being flowering plants):—*Acerophorus hispidus*, *Pteris serrulata*, *Platynerium alciorne*, *Nipholobos rupestris*, *Nephrolepis exaltata*, *N. tuberosa*, *Microlepia hirsuta angusta*, *Adiantum assimile*, *A. setulosum*, *Davallia bullata*, *D. dissecta*, *D. canariensis*, and *Drynaria pustulata*, and *Lycopods*, as *Selaginella denticulata* and *S. coccinea*; of Orchids *Cymbidium aloifolium*, *Aceropora Loddigesi*, *Maxillaria Harrisoni*, and *Stanhopea oculata*, *tigrina*, *grandiflora*, *Devoniana*, and *saccata*.

SELECT PERENNIALS FOR A TOWN GARDEN (Idem).—*Alyssum saxatile*, *Ajuga reptans*, *Agrostemma coronaria* vars., *Adonis vernalis*, *Alströmmeria aurantiaca*, *Iberis saxatilis*, *Iris reticulata*, *I. germanica*, *Lilium colchicum*, *candidum*, *martagon*, *chalcidionum*, and *hancifolium* vars.; *Hepatica angulosa*, *H. triloba* in variety, *Lychnis Haageana* and its variety *splendens*, *Lythrum roseum superbum*, *Mimulus ruscus pallidus*, *Paeonia alifolia* and *officinalis*, *Polmonaria corniculata*, and its variety *variegatum*, *hercaceous Phloxes*, *Polmonaria corniculata*, and its variety *variegatum*, which is the finest of all hardy variegated plants, *Primula acaulis*, double lilac, purple, crimson, white, and sulphur varieties; *P. auriculata* vars., *Pulmonaria officinalis*, *Pyrola* vars., *Salvia nemorosa*, *Scilla sibirica*, *Spirea filipendula plena*, *Thalictrum aemoneoides plenum*, *Trollius europaeus*, *T. napellifolius*, and *T. asiaticus*, *Tritoma Burchelli*, *T. nvaria* and its variety *glaucescens*, *Tussilago farfara variegata*, *Vincula elegantissima*, *Hesperis matronalis flore-plena*, *Geum coccineum grandiflorum*, *Fritillaria imperialis*, *Galanthus nivalis* and *G. plicatus*, *Erigeron grandiflorus*, *Draba aizoides*, *Dodecatheon meadia*, *Dielytra spectabilis*, *Pinks*, *Carnations*, and *Picotees*; *Delphinium formosum*, *D. Belladonna*, *D. alopecuroides*, *Convallaria majalis*, *Chrysanthemums*, *Cheiranthus Marshalli*, *Campanula aggregata*, *C. pulla*, *C. carpatia*, *Aubrietia deltoidea grandiflora*, *Antirrhinum*, *Columbines*, *Anemones*, *Arabis albidia*, and *A. bellidifolia*.

COLEUS VERSCHAFFELTI (A. Subscriber).—The plants you saw at Kew were in all probability this. It is extensively used there, and beds of it edged with *Cineraria maritima* have a charming effect. *Coleus* out of doors shows little, if any, yellow in the colouring of its leaves, it being much better and darker-coloured out-doors than in a house.

LAPAGERIA ROSEA CULTURE (Idem).—From seed, plants flower about the sixth year, and young ones now obtained will not flower to any extent until they are four or five years old. Turfy peat is the most suitable compost. You will find full particulars in No. 357, page 90, to which you are referred for treatment.

ELIGHIA SAPIDA (Idem).—*Elighia* or *Cupania sapida* (Akee-tree), is an evergreen tree attaining a height of 30 feet. It is a native of Guinea, and has been transplanted to the West Indies and South America. The fruit, which is highly esteemed in Africa, is reddish or yellowish, about the size of a hen's egg, and with an axil of a very grateful sub-acid flavour. The flowers are white. In this country it requires a stove temperature, and a compost of rich turfy loam.

SULPHATE OF AMMONIA (H. S.).—The chemist is quite right, a solution of sulphate of ammonia so strong would kill the slugs, and might be used for the purpose on vacant ground, but it would kill plants. We are not aware that the paragraph you mention appeared in our Journal.

PAPER ENVELOPES FOR FLOWER POTS (I. I. W.).—These are sold by the Association for Promoting the Welfare of the Blind, 210, Oxford Street, and 127, Euston Road, London.

LIME WATER (Julia).—If you look in the "Cottage Gardeners' Dictionary," which you refer to, you will find the information under the head "Lime Water."

OILING TREES (B. H.).—Painting the trees with train oil, including the buds, was a great mistake. We would, as you suggest, soak the buds well with a solution of washerwoman's soda, and the next day syringe them with water.

FERTILISING ACUCUA JAPONICA.—"F. H." would be obliged by Mr. Sayers, of Rockville, stating what is the utmost distance at which a male *Acucua japonica* might be placed from the female plant with a fair chance of success.

NAMES OF PLANTS (J. C.).—Your *Rhododendrons* are all florists' varieties, and we cannot undertake to name them. (*H. Dalton*).—We cannot undertake to name Hyacinths or any other florists' flowers. They are too numerous and so slightly differing. (*Durham*).—1, *Justicia assergens*; 2, *Dadalucaanthus* (*Erauthemum*) *nerosum*. (*H. M. E.*).—*Cheilanthes birta*. (*J. B.*).—1, *Aphelaxis humilis*; 2, *Centradenia rosea*; 3, *Acacia argyrophylla*. (*P. S. M.*).—*Lonicera*, probably *L. biflora*, but specimen too young to be certain. (*W. F. H.*).—*Narcissus jonquilla*. (*Improve*).—1, *Acacia leprosa*; 2, *Geuista canariensis*; 3, *Better specimen required*; 4, *Coronilla coronata*; 5, *Geuetychia triplicata*; 6, *Polygala oppositifolia*, var. *grandiflora*. (*J. T. Sinclair*).—*Lathra autumnalis*. (*B. C. H.*).—You must send a flower as well as a leaf of the *Spirea*. (*Nemo*).—We cannot name plants from mere leaves. If your Japanese seedlings flower, and you send us specimens of the flowers and leaves, we will endeavour to identify them.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending March 17th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

GAME FOWLS' TAILS.

GAME hens and cock chickens after fighting and being beaten always close and droop their tails, and carry their wings high up, while those that have just beaten them carry their tails up and fanned, and have their wings lowered and shielding their thighs, which is their most spirited attitude. Game fowls that habitually carry their tails low and folded, and their wings too high, are generally of a quiet and tame disposition.

My remarks on the whip and switch tails are in Nos. 300, 302, 324, and 328 of the Journal, and this, if "EXETER" had perused them, he would have known as a matter of course.

As to fighting qualifications the form of tail is, perhaps, of the least importance of any one of the qualifications, and at exhibitions great neatness seems to be chiefly aimed at in the form of tails. I look chiefly at the fighting qualities, and care little for exhibition birds in comparison, and still less for the judges' awards, unless they are really well-known first-rate Game judges.

I may also here deny the statement made by "EXETER," that I acknowledge Brown Red cocks with black-marked breasts, and black-bodied Brown Red hens, to be the general favourites. I never stated this at all, though at the last Birmingham Exhibition I believe the black-bodied Brown Red hens took all the prizes in their class. I think, on the contrary, that the Brown Red cocks with the brown-streaked red-brown breasts are the favourites, and next, these with clear red-brown breasts; and that the pencilled dark Brown Red hens are in general the favourites, striped-hackled of course. Black marks on a Brown Red cock's breast show the Black-breasted cross in them, and are, undoubtedly, a sign of impurity. The pencilled Dark Brown Red hens are also in my opinion much more beautiful if with the coppery-red dark hackles than any black-bodied hens, and so many others think. The black-bodied Brown Red hens with the yellow hackles are also inferior to dark-red-hackled hens; both are striped-hackled of course. The willow-legged strains of the Brown Reds are also cross-bred mongrel birds from the Black-breasted willow-legged breeds, and are inferior in hardness and gameness to the blackish-legged strains. The willow-legged Brown Reds appear to be coming into fashion at exhibitions, and although too soft are often fast birds, though none of them true-bred Brown Red Game.—NEWMARKET.

HENS LAYING IN WINTER.

I BELIEVE hens will usually lay in winter if well fed. Good barley, tail wheat, and white peas, will assist them. In Sussex, where chickens are raised all the year round, the farmers' and cottagers' wives make their hens lay by liberal feeding. Even if pullets lay, they do not care to sit their eggs. The hens need not be very old, I have several laying now, and some sitting. I do not keep mine so well, as I do not rear chickens for the market. Mine have a gallon of barley in the morning, divided among Ducks, Turkeys, and fowls, about fifty in number. I send to the mill two bushels of oats, and one of barley, and have them ground together; this, mixed with bran or pollard, makes a good meal for the afternoon. It is best given warm, wetted with hot water, or water that has been used for cooking purposes.—L. B.

ACCRINGTON POULTRY SHOW.—We have received a prize schedule of the Poultry Exhibition that will be held in the

first week in April, and it proves to be a very liberal one. To each class there are three prizes of 30s., 15s., and 5s., respectively; but to the class for Single Game cocks there are to be awarded a silver cup of five guineas value, or the money, and £2 and £1 as second and third prizes. To the Single Game Bantam cock class will be awarded £5, £2, and £1, and to the best pen of Hamburgs of any breed, a silver cup of the value of three guineas. In the Pigeon classes the prizes will be 10s. and 5s. to each variety. The rules state "all poultry and Pigeons will be exhibited under cover, on the same elevation, and in equal light; and all prizes will be paid within seven days of the Show." Under such favourable provisions we may anticipate the entries will be numerous, and the quality of the birds superior.

SOMERSET COUNTY POULTRY ASSOCIATION—EXCESSIVE RAILWAY CHARGES.

"BRAHMA" in an article in your Journal of the 12th inst., denies the correctness of my statement of the 5th inst. I beg again most distinctly to state, that "BRAHMA" was not charged 5s. 3d. by the Somerset County Poultry Association for the conveyance of his fowls from the railway station to the show-yard.

I paid the Bristol and Exeter Railway Company £15 18s. 7d. for the carriage of fowls to the Exhibition, the said amount being charged in 261 different items; and from the accurate mode in which their accounts were rendered, I find that each item so charged had reference to the number on the respective hampers, and some for further reference contain the name and address of the reputed owners. I have before me the railway company's receipt and in it I find the following entry, "Baskets of poultry from Paddington to Weston-super-Mare (name of owner which we will call "BRAHMA"), 4s. 11d., and for delivering and collecting 4d.—5s. 3d.

I challenge "BRAHMA" or any other exhibitor of fowls at our late Show, to prove that the smallest named fraction of a penny has been charged them by us beyond what is charged in the railway company's receipt. If there has been any excessive railway charge, the aggrieved parties have a redress by making application to the Bristol and Exeter Railway Company. I have offered various exhibitors to help them to get repaid, if they will send me a receipt that the carriage was previously paid by them, but not one has done so. "BRAHMA's" idea that my not replying to Mr. Percivall's article confirms the truthfulness of Mr. Percivall's statement is absurd, the charges made upon Mr. Percivall and "BRAHMA" were under precisely similar circumstances.—BENJAMIN COX, *Hon. Secretary*.

[Here this controversy must cease from our columns. It is now a mere personal matter.—EDS.]

PRIZES FOR DUCKS.

I NOTICE in your impression of February 13th, a complaint respecting the preference shown by the Judges in awarding prizes to the ornamental varieties of Ducks over the useful. Poultry shows profess to be for the improvement of all kinds of domestic poultry, and this is generally so stated in the schedules. This being the case, are judges justified in giving prizes to those fancy Ducks which are not domesticated, and leaving out the domesticated and useful kinds, such as East Indian, Grey and White Call, &c.?

At Manchester they have a class for Ornamental Water Fowl, and if other shows would add such a class (either domesticated or undomesticated), I think it would meet the require-

ments of the case, as there is no denying they are very beautiful, and a great attraction in any show; but so long as committees of shows offer prizes only for domesticated poultry, let domesticated poultry have the prizes.—G. K.

A GUIDE TO CANARY BREEDING.—No. 2.

BEFORE proceeding to put up breeding stock, a few words about breeding cages.

The most useful for all purposes are what are called "two-couple" cages—that is, containing two compartments. Many breeders use cages with a greater number of compartments than this, ranging from ten to twenty or more. Such cages are, however, nothing more than a multiplication of the smaller one, with the disadvantage of being more cumbersome. It is, perhaps, only a question of taste, but the smaller cages have the advantage of being more easily moved, and more readily cleaned—a great desideratum. The simpler the construction the better. To a practical man there is a wide difference between the appearance of a cage which looks like business, having every necessary appliance but no more, and one which, while it may be a creditable specimen of the cabinet-maker's skill, is only a useless ornament, altogether unfitted for the purpose for which it is intended.

The best cage is simply a box 3 feet long, 18 inches high, and about a foot from back to front, divided in the middle in the direction of its width by a fixed or moveable partition, having a small door in the centre, which, revolving on a single screw, will open or close an aperture serving to connect the two compartments. The door of each division should be made large enough to admit the hand and allow it free motion in the inside for the purpose of whitewashing, an operation necessary at the beginning and end of each breeding season. A still better plan is to have the front attached to the cage with screws, so that it can be removed at pleasure, a method which affords greater facility for thoroughly cleansing than by means of the door.

The wires may be half an inch apart. There must be a water hole at either end, and four seed holes in the middle, two on either side of the partition, giving access to the seed hopper, which must in the first place be covered so as to prevent the birds throwing out the seed, and also be divided into two parts by an upright partition, as the cocks, being very pugnacious while the hens are incubating, will exchange a passage of arms through the seed holes, if they can reach each other. There are a great many contrivances for seed hoppers, all more or less ingenious. Simplicity is, however, a great essential. The main objects to be attained are a regular and certain supply of seed, so protected that it cannot be wasted, and still accessible to the bird without injury to its head, an important matter with crested birds. A sliding bottom to the cage, with a raised rim to hold the sand, with which it should be freely sprinkled, will be found a simple and clean arrangement.

Having procured such a box, proceed to give the interior a good thick coat of whitewash, formed by mixing common whitening and milk—a mixture which will not easily rub off. Be very careful to fill every crevice. This is of extreme importance, as the red spider, a parasite which persecutes the Canary more or less at all times, but particularly when nesting, and which is the great bugbear of breeders, to exterminate which is their constant aim, and to effect which object various nostrums are prescribed, will establish itself in countless numbers in the minutest cracks, leaving its hiding places after night-fall to prey on the very life blood of the young birds, and retreating to its fastnesses at break of day. Having whitewashed the interior, coat the edges of the box thickly, and white each screw in the front, taking care that it fits closely, the whitening acting as a cement behind it.

The rest of the apparatus consists of nest boxes of various sizes. Wooden boxes are most in vogue in the south; in these the hen will construct her own nest from a supply of moss and doe hair, which must be furnished her. In the north, however, tin nest boxes fitted with artificial nests of felt are generally used. A few egg troughs of tin or earthenware, a box about 6 or 8 inches square and 2 deep, having a bottom of perforated zinc for passing hard-boiled egg through a piece of felt such as is used for stuffing saddles, and a bath, which is a small cage about 8 inches square, entirely open on one side, and containing a zinc or earthenware trough, with, a few water fountains, about complete the necessary appliances.

A few other trifling accessories may suggest themselves as occasion requires, but with these necessities the beginner may "put up" his birds, one pair in each compartment, giving them in addition to their usual supply of food (which should be a mixture of Canary seed and summer rape, with occasionally a little linseed, millet, or maw seed by way of variety), a little chopped egg and crushed hempseed every day. This being very stimulating assists in getting them into high condition.

A nest formed by cutting a piece of felt into a circular shape, and splitting it in halves, as it would otherwise be too thick, should be tied into a No. 1 size nest box, and the tin suspended by a small nail at the back of the cage between the two perches, which, by the way, should not be like those small affairs sold in ornamental song cages by ironmongers, but nearly half an inch square, and only slightly rounded off at the edges, affording the bird a secure resting place for its food without having to contract its toes in an unnatural way to grasp the perch.—W. A. BLAKSTON.

LIZARD CANARIES.

AFTER perusing Mr. Blakston's very sensible remarks on Canaries, I would like to ask the opinion of fanciers how to determine the essential qualities of a show bird in the Lizard classes, and I believe I am right when I state that no other variety of Canary is so imperfectly understood, or regarding which there is so much diversity of opinion among fanciers. I would receive thankfully the opinions of fanciers on the following questions, and also any extra remarks.

1. Is depth of colour as much an object in Lizard as in Norwich or Cinnamon Canaries?

2. Is a bird with golden spangles intermixed with silver, or silver-tipped spangles, to be considered a show bird; and in which class ought it to be entered—gold or silver, or neither?

3. In what class should a bird be entered that in ground or body colour is almost yellow, with a cap as high in colour as one of the best Mealy Norwich cocks, yet its spangles are all silver?

4. Is it a fault or point of excellence for a Lizard to have a spangled appearance on the breast as well as on the back?

In the latter part of 1866 a friend of mine had two Silver-spangled Lizard cocks, both good-sized and excellent birds, of about equal quality in size and regularity of spangles, and each bird had well-shaped caps; I will term them Nos. 1 and 2. No. 1 was a bird of a good buff colour on body and cap. No. 2 suggested my third question, for the ground or body colour was a very high mealy colour, almost as good as a yellow, with a cap as high in colour as a prize Mealy Norwich cock. The birds were exhibited four times together in one class at some of the very best shows, the bird No. 2 taking the first prize on two occasions. There were different judges at each exhibition. On the other occasions on which they were shown No. 1 was very highly commended at one show, and took a prize at the other show; but in both cases No. 2 was not even commended when one of our most noted judges officiated, though at each place assisted by different persons. On one of the latter occasions the bird had the appearance of having been tested, to ascertain, I suppose, if the colour was spurious. These two Lizards have been exhibited many times besides those above mentioned, when I believe I am right in stating they always took prizes.

I noticed a Lizard last season, that with the exception of having both gold and silver spangles on its back, and with body colour of a palish yellow, is, in my opinion, a very good bird, and has taken prizes at some of our largest shows in the Golden Lizard class. This bird comes under my question 2, yet I do not think it can be termed a Golden-spangled Lizard. R. HAWMAN, 94, Marston Road, Middlesbrough.

CONSEQUENCES OF MISMANAGEMENT.

MAY I ask if you think it desirable for me to feed my Ligurians now, as I find them very weak? I have never had any honey from them, and I should have thought they might have collected honey enough last season to keep them till summer again, as the English bees have done, but I am rather frightened about them.

The English bees are now working well, but those horrid Ligurians only come out in the finest part of the finest days. They appear to be few and languid. As they cost so much, and are said to be so good, I should like to keep them if possible, hoping for better times. Why are they so much more

lazy than the old John Bulls? Are they very tenacious of cold? It is very tantalising to hear of their doing so well with other people, and so badly with me, and they have been well treated. They swarmed three times last summer, very weak swarms, two of which are dead.—S. S., *Tiverton*.

[You have omitted to state that you last year drove a large artificial swarm from those well-treated (?) Ligurians at a time when they were unable to provide themselves with food, and then suffered them with the original and pure queen at their head to perish miserably by starvation! From this ill-advised proceeding have arisen all the subsequent misfortunes of which you now complain; the stock, which was at the outset an amazingly strong one, having been completely ruined by mismanagement. If it now possesses a fertile queen, something may yet be done to promote breeding by the judicious administration of food, but the recovery of a colony which has once been reduced to so low an ebb can at the best be but slow, and the ultimate result is extremely uncertain.

To satisfy yourself that the present languid condition of the Ligurians is entirely owing to paucity of numbers, and not to their being susceptible of cold, you have only to recall to mind their energetic activity at this season last year. It was unfortunate that the stock should have swarmed naturally after the forcible abduction and destruction of its ill-fated queen, and the great bulk of its hapless population, but such swarms must necessarily have been very weak and could scarcely be expected to survive the winter. They should, indeed, have been at once returned to the parent stock, which in this case might probably have recovered from the effects of your previous ill-judged manipulations.]

BEES NEGLECTING ARTIFICIAL FOOD— PRUNING COMBS, &c.

Why do my bees refuse to feed now? They have not much honey—not more than 2 or 3 lbs.—and yet they are very active, not at all weak in numbers for the time of year, being almost as strong as they were at the commencement of winter. I feed them with loaf sugar and water, and yesterday I smeared the feeder with some peppermint water, thinking the smell might attract them to it, but all to no purpose. Do you think the bees can get any honey from the flowers yet? We have only the apricot trees in blossom, though pear trees are nearly ready to flower. The bees carry also a good deal of pollen into the hive, which I think they have from the elms.

What do you think of the mode of cutting-out comb in the spring as practised in Russia? Do you think it is of any use, or does it only give the bees extra trouble?

Can bees be placed near a house without causing trouble? Are they likely to come into the rooms?

Do bees thrive as well in an open space as under the protection of a wall or hedge?—CAROLUS.

[The fault is not in the food, but in the mode of administering it. If you discard your present feeder, and adopt the inverted bottle, your bees will speedily emulate our own, which are now appropriating food in any quantity that we think fit to indulge them with. Bees cannot as yet collect sufficient honey to maintain themselves, although in exceptional seasons we have known them build combs in March. It is so very seldom advisable to prune combs in spring that it is better entirely left alone. Bees rarely enter rooms, except by accident, unless enticed to do so by the exposure of honey or other sweets. There is no doubt that they thrive better in a sheltered than in an exposed situation.]

FORMING AN ARTIFICIAL SWARM IN A UNICOMB HIVE.

I HAVE an empty unicomb hive into which I wish to introduce an artificial swarm: would you let me know how soon I can set to work? I wish to put a piece of brood comb for a Ligurian hive into the unicomb hive, and place it on the old stance of a black hive in order to make the black bees rear a Ligurian queen, and after the bees are settled in the unicomb hive, and the queen has been raised, I wish to remove the hive into the conservatory. Do you think this plan will succeed?—ALFRED FINDEISEN.

[The proposed experiment is very unlikely to succeed, as a unicomb pure and simple is the worst possible hive for the

operation. Your best plan will be to have the unicomb hive fitted with moveable comb-bars in the manner first invented by Mr. Woodbury, get a box made to take these bars ranged side by side in the usual way, and in this make your artificial swarm early in May. As soon as the young queen begins egg-laying, the combs and bees may be shifted to the unicomb. When removing a brood comb from the Ligurian stock for the purpose of forming an artificial swarm in the manner you describe, you should take with it the adhering bees, but make certain that the queen is not amongst them by first ascertaining her presence on another comb. The box should also be furnished with worker combs, for if any are built before the queen is hatched they will be sure to be drone combs. "The Gardener's Almanack," which contains Mr. Woodbury's Bee Calendar, may be had post free from this office for thirteen stamps.]

OUR LETTER BOX.

BOOKS (*D. Williams*).—Brent's "The Pigeon Book." You can have it free by post if you enclose twenty postage stamps with your address.

SPRING CHICKENS—FOWLS (*Georgie*).—Spring chickens should be about twelve weeks old when killed, fowls from sixteen to eighteen weeks when put up to fatten. Fowls will grow more and become more mature in fourteen weeks in the spring and summer than in eighteen in the winter.

CRÈVE-CŒURS (*Young Beginner*).—Fowls without beards are not Crève-Cœurs. They should be square, short-legged birds, with top knot and beard, and small comb in front, resembling somewhat a cloven heart. They take their name from it.

MARKING FOWLS—BUCKWHEAT FOR POULTRY (*Tyro*).—The best plan of permanently marking fowls is to perforate the web of the wing with a red-hot iron. Buckwheat is not good food for fowls, nor do they like it. They like nothing of an oleaginous nature. Asphaltum is a very bad thing for the flooring of a poultry house and yard. Birds will never do well upon it, nor will they be healthy.

HATCHING GEESSE—KERRY COW (*Z.*).—A hen would hatch a Goose's eggs, although she would have to incubate nearly a week longer than if sitting on her own eggs. They ought to be sprinkled with water daily. A Kerry cow would repay you, if you have the conveniences and keep useful for a cow of any kind; but you should keep two.

ULCERATED INTESTINES (*Canker*).—What is called in Staffordshire "canker" in fowls, is an ulceration of the intestines and other viscera. There is no medicine known to cure the disease. When a fowl mopes about, the only chance of saving it is by giving bread soaked in ale to keep up the bird's strength. If the ulcers become numerous there is no hope.

BUCKWHEAT (*A Constant Reader*).—Buckwheat may be purchased of any of the principal seedsmen who advertise in our columns. It is sown in May.

FOWLS VERY FAT (*Trotters*).—Poultry if kept too fat will not lay, and, perhaps, the introduction of a young and lively cock in perfect health, about two years and a half old, would give a good supply of eggs. Giving fowls too much barley is as bad as giving them too little. Give them a change of food—oats, barleymeal, and green food, such as lettuce, hoiled carrots, and parsnips; also scraps of animal food about twice a week. Mashed potatoes mixed with a little bran are good as a change of diet.

POULTRY BREEDING.—We have received Mr. Volkman's reply to Messrs. Ure and Stuart, but through pressure of other matter we are unable to insert it in this number. It shall appear next week.

PIGEONS (*J. Spence*).—You will see in our columns by degrees the information you need. If you consult "The Pigeon Book," which you can have from our office free by post if you enclose twenty postage stamps, you will find what you require about Jacobins.

PARROT WITH TUMOUR (*H. T. Toy*).—For the Parrot having a tumour under its eye we fear there is no immediate remedy. It may be from cold, or through the bird having pecked the brass of the cage, or that the feeding boxes have not been properly cleansed. Give it some bread and milk, scald the bread first, also a few chillies, and if it will not eat them sprinkle a small quantity of Cayenne pepper amongst the seed. Touch the parts of the eye and tongue affected with warm water two or three times a day, using a camel's-hair brush, and about an hour afterwards with a little cold cream (which is to be had at any chemist's), not sufficient for it to swallow. Give it also a piece of bread soaked in very weak rum and water; also try a little warm tea, and give plenty of fresh water.

CANARIES SINGING (*Trotters*).—Cock Canaries hatched in July last ought now to be getting into song, if they have been kept in a room with other singing birds, but if they have been kept by themselves they would only twitter a little. The throat of a cock swells when he twitters, but that of the hen very little.

POULTRY MARKET.—MARCH 18.

Our supply of poultry becomes daily less. The winter birds are getting hard. The birds of this year are not forward enough. We hear good accounts of the early broods.

From observations taken near London during the last forty-one years, the average day temperature of the week is 53.6°; and its night temperature 33.9°. The greatest heat was 75°, on the 27th, 1830; and the lowest cold 16°, on the 1st, 1838. The greatest fall of rain was 0.76 inch.

RAMBLINGS IN GREENHOUSE, GARDEN, AND WOODS.

I CAN testify to the soundness of the advice given to "A SUBSCRIBER" in the Journal of the 13th ult. relative to striking cuttings over a flue. If he carry out the instructions there given, I am sure he will acknowledge the usefulness of such a miniature propagating house. I have a similar place in use here. The flue from a plant stove runs across the end of a span-roofed greenhouse. The greenhouse stage is flat, and

about 18 inches above the flue. From the floor up to the stage is closely boarded, enclosing the flue. The whole of the heat is thus directed upwards through the stage, on which is placed a glass case, opening at the top with a hinge. A few slates are placed inside to prevent the sawdust, in which the pots are plunged, falling through the stage. The heat communicated is abundant and sweet; scarcely anything which I put in fails to strike quickly; in short, the place is invaluable, always ready for work, and the heat quite under command by simply having a slide in the boarding which encloses the flue. Water must be poured on the sawdust to keep it uniformly moist: a mere sprinkling on the surface is not sufficient. Avoid dryness at the bottom of the sawdust, and success is certain. I may add that the house in which this case is placed is always gay with flowers, and so far from the case being an eyesore, its manifest utility claims a meed of praise from all visitors, who ever evince an interest in its crowd of little occupants, and the progress they make from day to day.

I will now take a ramble in the open air, and spend a few minutes amongst Potatoes. I can offer no remedy for the disease. The mystery remains as profound as ever. Observation of the time of the visitation of the disease, however, has been of some use to me. Of the varieties of Ashleaf I have taken up for seed, I may safely say that for the last eight years not more than 1 per cent. of the tubers has been affected with the murrain. I took my cue from an old shoemaker, who for many years prided himself on producing early Potatoes a week before his neighbours. His secret was this:—"Take them up when the tops are quite green; never mind their slipping their skins, they will soon grow new ones." "Will they keep if treated thus?" was my first question. "I never had a bad one in my life," was his reply. "Come and see my stock." This was in a year when the disease was unusually virulent, and Ashleaves were nearly exterminated in the locality. I went to see, and believed. He alone in the village had a fine stock of healthy tubers. I have practised the method ever since, but each time leaving a few in the ground for experiment and observation. Every year has given the same results. Those taken up when the tops were quite green have kept perfectly sound, while those left longer in the ground, until the haulm died naturally, have rotted more or less according to the season. The idea of procuring an earlier produce by this plan I think but little

of. It is the man's fancy, and he has a right to exercise it. The keeping of the Potatoes is of greater moment, especially as the produce, as sets, is in no respect deteriorated. A village shoemaker's shop is a notable rendezvous; "chaff" there predominates, and the shoemaker was provided with a goodly share about his skinned Potatoes; but he has a victorious reply when their keeping properties are assailed. He then slyly opens his drawer, bringing out an old friend, with the observation, "Show me one older than this, then I'll give in." I saw this specimen three years ago. If he has it yet it is in its teens. There is no semblance of romance here. I believe the man is still living, and any one can have his address through the Editors, and they will find what I have stated bare uncoloured fact.

My plan is now this: About the second week in June, when the atmosphere is in a highly electrical condition, and a thunderstorm occurs, I take a scrutinising ramble amongst the crops, and when I detect the very first speck of disease on the foliage I take the Potatoes up at once, leaving in the ground a few only for daily use, or even if I see any disease in the neighbourhood the warning is sufficient, and I set to work immediately.

In 1866, when on a visit to a neighbouring gardener, I saw the disease undoubtedly at work. I took my main crop up the next day, and every tuber kept well; a few by the side of them, and left in the ground some time longer, went bad at the rate of 50 per cent. Last year I again took timely warning, and up to the present time I have not found one decayed tuber. A few I purposely left for observation—parts of rows from which the above had been taken—and the majority of them rotted either before or after being taken up.

I am led into this rambling by the remarks and queries of "HAWKINS" on page 149. I will now take text from the latter portion of his letter, and look at late-ripening kinds of Potatoes. My rambles here will be general, and to a great extent speculative. I am decidedly of opinion that the Onions had nothing whatever to do with the exceptional soundness of the Potatoes which had come up amongst them. I have seen Onions, intended for seed, grown amongst Potatoes, and the Potatoes were worse rather than better of their company. The immunity from disease I trace solely to the fact of the foliage not being allowed to develop itself until late in the season, and after the deadly scourge had in a great measure expended its activity. I have at various times planted exceptionally late, and the crop has in a great measure escaped the disease; but then the produce was poor, and the quality poorer. The natural inference from these remarks will be, that I believe the murrain to be communicated by atmospheric agency, and through the medium of the foliage.

The Potato, like most other plants in the early stages of its growth, is dependant chiefly on its roots for its supply of food. In the development of leaf-formation another all-important source of supply is unfolded. When the plant is in full vigour the leaves are performing important functions, not only in elaborating the sap obtained by the roots, but also in inhaling the constituents of the sur-

rounding atmosphere. It is by this means that the plant supplies itself with the requisites for its perfection; or, on the other hand, receives into its system elements directly inimical to its wellbeing. Thus its very efforts to sustain health and life may, and indeed do, often result in disease and death. Now, whatever the roots of plants may do in the matter, it is certain the foliage does not exercise a power of selecting atmospheric food. Plants can no more reject a poisonous inhalation than the collier can the noxious gas which proves so terribly fatal; but it is when the plants are in an advanced stage of growth that they receive the greatest injury from the poisonous state of the air which for the time being surrounds them. Their organs of respiration are then fully developed, and in active operation. In the absence of, or whilst these organs are imperfectly developed, which is the case when the plant is in its earliest stages of growth, it will in a great measure escape a passing atmospheric scourge. This has been demonstrated to most, or I may say, all gardeners. When the air of a dung frame is saturated with poisonous gases evolved during the decomposition of manure, and plants of any kind are put in, they will be speedily killed. But it is not the leaves lately expanded—the youngest and, as we might think, the most tender parts of the plants which are first injured—no, it is the fully developed foliage which first succumbs. It breathes the poisonous air, and death ensues. My attention was first attracted to this subject before I was the age of the shoemaker's Potato. It set me thinking, and I have continued to think and watch, until I imagine there is some analogy to the Potato disease here.

The cottage where I was born is now razed to the ground. If its date of erection was not antecedent to the introduction of the Potato into this country, it was at any rate sufficiently remote to warrant us in a belief that the site of the cottage had never produced a crop of Potatoes. Here, then, was a fresh piece of ground, and it was planted accordingly. The mud walls and rubbish from the building formed the soil, to which were added a few loads of sand. The crop was prodigious, but considerably affected with disease, except a few early Potatoes taken up in July, and a late-ripening pig Potato, which was also nearly exempt from it. Now, where did this disease come from? It could not well be in the soil—perhaps it was introduced with the sets. Well, it might have been so, though I do not think this was the sole cause, or why did not the tubers turn bad which were taken up early? The immunity from disease which late-ripening kinds seem also to some extent to possess is becoming more and more acknowledged. A fact not to be overlooked is, that the working classes and cottagers are generally discarding mid-season varieties for the greater certainty of sound crops of the later kinds. With them quantity is the primary consideration. Late Potatoes as a rule are inferior in quality. If Paterson's Victoria possesses all the excellencies which it is credited with, it is a step in the right direction. I know nothing of it, and so leave it and all the rest just for a short ramble in the woods, where so many of my boyhood's happy hours were spent.

I can confirm "A SOMERSETSHIRE PARSON'S" plan of sticking elder round the young trees to protect them from rabbits. The plan is effectual, and, fortunately, any other kind of sticks with which the ground happens to be strewn will answer well. My father was for many years woodman on an estate where some thousands of trees were annually planted, and the rabbits and their ravages were a constant source of anxiety to him. He tried several modes of protection, but sticking round the trees with whatever was most handy he considered the most effectual and economical plan. He considered it was only allowing a man six days to put in a given number of trees instead of five. The last time I looked carefully through a piece thus protected I did not see one tree injured. In this instance the sticks used were dead Larch and Spruce. This was his plan after thirty years' experience and anxiety.—J. W.

[We insert the above, but we totally dissent from what our correspondent says relative to plants inhaling noxious gases.—Eds.]

REMOVING LARGE TREES.

In compliance with Mr. Flitton's request, I have to state that I obtained much benefit by the use of old netting, such as has been used by fishermen, for wrapping up the ball of earth before attempting to move the plant, and securing the same by cords. By this means the ball is secure, and can be shifted without loss of soil; and in most cases the net may in part

remain on the ball, as it will soon rot away. I have found this advantageous in transplanting large Portugal Laurels, as they will not live if the ball is cracked or severed in the least degree.—WM. THOROLD, *Thorpe Bower, Norwich.*

BUSH FRUIT TREES.

THE letter of "C. C. E." (see page 198), is a word in season. How much I wish he had a thousand imitators, so that we might learn the great difference that soil, climate, and management make in the success or non-success of fruit-tree culture in gardens.

Before I go into further particulars I must promptly clear myself of what would seem, according to "C. C. E.," to be a little misrepresentation. I repeat with great confidence that an active man can lift and replant one hundred trees in a day. I have always made it a point not to report on any experiment till I had tried it. This was the case with the lifting and replanting of dwarf trees, for I found some years ago that one of my active labourers would finish off twelve in one hour, and so I modestly put the number at one hundred per day. I must, however, confess that when I saw the assertion of "C. C. E.," that it would require two good men to do the same work, I felt a little shaky, and quite thought that my memory had been at fault when writing the paragraph. I soon ended my trouble, for I at once called one of our active workmen, and told him to bring his treddle spade. This is an implement made here of enormous leverage, and with which, if I descended to hetting, I should back a man accustomed to use it to remove three trees while another with a "garden spade" would remove one. It is odd to find so near London so much of the old country customs and prejudices that exist in this neighbourhood. Our workmen's favourite Vulcan lives some four miles off, and although there are five smiths in this large parish, they declare that not one of them can make a good spade. This home-made spade is heavy, is always sharp, and by the clever workmen is wiped clean at night, and kept bright as silver on both surfaces. It measures 15 inches from its lower edge to the upper part of the treddle, and, consequently, can be thrust into the ground to that depth.

I must return to my tree. My man shouldered his spade and went with me to my one hundred trees of Cox's Orange Pippin Apples on the English Paradise stock, which have been planted six years and twice removed. I directed him—my watch in hand, unseen by him—to dig a trench a spit deep about three-fourths of a circle round the tree selected, and 9 inches from its stem, leaving a portion of earth solid. Into this solid portion, after digging the trench, he thrust his spade in a slanting position so as to go under the roots of the tree, he then with strong arm lifted it with nearly all its roots intact, for only two or three small ones were fractured. No root-pruning was required, for owing to the tree having been lifted two years ago its roots were compact. He then made a slight hollow in the place it was taken from, replaced the tree, trod the earth firmly round it, filled-in and levelled the loose earth, and not till then did I look at my watch to ascertain the time it had taken to do all that I have described. The hand was at ten when he commenced, and when all was finished it was exactly three minutes past ten, or as we now write, 10.3. (What a concentration of strength and energy there is in a skilful English labourer! I have never yet seen his match.) Well, the tree was, I repeat, finished in three minutes. Now, I wish to be liberal, and so I allow two minutes in the absence of "master" for back-stretching, and this will give five minutes for each tree, or twelve trees in an hour, and this is easy work; but it must be understood that it is only Pears on the Quince, Apples on the Paradise stock, and Plums, all under occasional removal, that can thus be operated on so quickly, their roots being compact and requiring no pruning. There is, however, so much difference in soils that it is difficult to estimate the labour required, for in some soils a tree left undisturbed for two seasons will make long shoots and long straggling roots, so as to require some care in lifting and replanting.

All the varieties of soils here, whether tenacious clayey loam, dark vegetable soil resting on gravel and clay, or light sandy loam resting on sand, are highly calcareous, and I feel almost assured it is owing to this that every kind of fruit tree is inclined to early fruitfulness if checked in its growth. Thus a vigorous "maiden tree" (a tree one year old), of a Pear on the Quince, or an Apple on the Paradise, or a Plum, if taken

up and replanted, say in March, will the following season be a mass of blossom buds, and destroy itself by overbearing. I have under my eye a border some 14 feet wide and upwards of 100 yards long, planted with bush Pear trees, one thousand in number. They are about 18 inches in height, were planted last March, and now every tree is a mass of blossom buds.

I must confess that my love for bush fruit trees increases annually. I admire a fine well-managed pyramid, of which I have a goodly number, but there is here a great evil attending their culture. Our Atlantic gales or westerly winds which blow over the whole surface of our little island of Great Britain with such intensity, and are unknown in the interior of the continent, are terrible disturbers of pyramidal Pears on the Quince stock, as these do not root deeply. I have some, now twenty-five years old, which if they were not supported by a stout prop on the eastern side of the tree would be nearly prostrated. These necessary props are hateful in my sight. A bush tree however old and loaded with fruit is never disturbed. I ought to add for the comfort of those who have planted pyramids, that those I allude to are planted in an exposed place with no sheltering hedge or wall.

With regard to the distance from each other that bush trees should be planted, the matter is quite worthy of consideration; very fortunately I am able to throw some light on the question, owing to my having some plantations of bush Pear and Apple trees from ten to fifteen years old. In another place I have recommended a sort of nursery fruit garden, the trees, Apple bushes on the Paradise, to be planted 3 feet apart; or in case the plan were carried out extensively by market gardeners, to plant the required number of stocks, 4840 per acre, and to graft them.

It is now six years since I carried out the idea by planting one hundred Cox's Orange Pippin Apple trees on the English Paradise, 3 feet apart, row from row, and 3 feet apart in the rows, intending to carry out my suggestion of removing every alternate tree at the end of seven years, and after the lapse of a few more years to remove every alternate row so as to leave the trees 6 feet apart as the permanent distance. I have just looked over this plantation, and find that the trees that have been twice lifted are compact and will soon be perfect nosegays of blossom. They may to a certainty remain two more years before there will be any necessity to remove every alternate tree to a fresh plantation. This will make a period of eight years in which they have remained 3 feet apart without being crowded, so that I was quite correct in my suggestion that bush trees could be planted at the above distance with a good result. I ought to mention that this close planting is better adapted for very small gardens, and for market gardeners who would wish to have their ground occupied with fruit trees without any intermediate crop.

I ought to tell everything pertaining to my experimental plantation, and must refer to one row of trees in it. These have been lifted only once, they are full of blossom buds, but are double the size of the others, and must be thinned-out next autumn by removing every alternate tree. In another plantation of bush Apple trees, four hundred in number, sixteen years old; and in a plantation of bush Pear trees, five hundred in number, ten years old, the trees are 4 feet apart in the rows, and 4 feet apart row from row, and this I believe to be the proper distance to plant bush trees in gardens, unless it is wished to crop between the rows and to allow the trees to grow without being occasionally lifted, and then 6 feet will be the most eligible distance.

The mode I have adopted with the above plantations is to lift any tree that seems inclined to grow vigorously, and not show symptoms of bearing, leaving those that grow more slowly unmoved for three, four, or more years, or till they are inclined to make growth rather than fruit. I have reason to believe, from long observation, that the occasional removal of garden fruit trees tends greatly to their well-doing in this country; or, as a pomological friend writes from the north of England, it is the "life and soul of fruit culture." With some kinds of trees and in some soils root-pruning without lifting is equally efficacious; but while writing the above I have had in my mind only such fibrous-rooted trees as Pears on Quince stocks, Apples on English Paradise Stocks, and Plums.

It may give some gleam of comfort to "C. C. E." to be told that in 1866 I had but a scanty crop of Cox's Orange Pippin on my bush trees, and in 1867 not a single fruit. They were masses of blossom, but the frost of May 25th destroyed all. The scourge was so effectual that, although I have in some seasons had from two to three hundred bushels of Sturmer Pip-

pins, last year not a fruit was gathered; in fact, I never saw one. It is very charming and hopeful to see the fruit trees this season so crowded with blossom buds; but alas! we must bear with our uncertain but healthy climate, the glittering blossoms may and probably the greater portion of them will, be cut off. One seems almost to envy the climate of the French gardeners, who, towards the south-western districts of France, have but little anxiety about their fruit crops.

With respect to diagonal cordon training on wire fences, the height of 4 feet is given as the minimum, to be increased according to position. Here it seems to be a pleasant height for the cross walks in the interior of a garden, as it does not interrupt the view. For a boundary in any convenient place, 8, or even 10, feet is not too high. I am a great lover of fruit-tree culture in all its modes. I delight in all the cordons, except the single lateral, which now always seems to me incomplete, and I feel a mischievous tendency to paraphrase Pope, and say, Each branch should have its brother; but my great and increasing love is for bush Pear trees on the Quince stock, ditto Apples on the Paradise, and Plums, they are all so easily managed, and their blossoms protected. The trees, as is well known, have no leaves while in bloom—give them leaves in the shape of dry hay or branches of evergreens.

If "C. C. E." would kindly give the nature of his soil and subsoil, and the site of his plantation, whether high or low, also whether he lives north, east, south, or west from London, he would add much to the value of his communication.—THOS. RIVERS.

WHY ARE AURICULAS NEGLECTED?

As a lover of the Auricula, and one of that select few who grow the flower, I think I have a just cause of complaint against our two great Societies for the manner in which it has been this year treated. Some few years ago it was becoming almost an unknown flower. About the metropolis there were a few who grew it. The mantle of poor John Dickson, of Acre Lane, had fallen upon Charles Turner, of Slough. Mr. Butcher, of Camberwell, and others still retained their love for it, though General Tom Thumb and other vulgarities had so pushed Auriculas on one side, that people were almost ashamed to acknowledge that they grew a collection of them; but the spring exhibitions of the Royal Horticultural and Royal Botanic Societies once more introduced them into notice. The prizes offered were indeed small, but they acted just as a sufficient stimulus to induce growers to come forward. We had our boxes made for bringing the plants up to the exhibition, and we were rewarded by seeing the interest shown by nearly every one who took the trouble to examine them. Then we had the National Exhibition of Auriculas, which brought together growers from north, south, east, and west, and for many years such a sight had not been seen in London. Well do I remember the unfeigned astonishment of the visitors, who asked what could these flowers possibly be. And I do not wonder at it. There is no flower at all like them. There is a refinement, a richness of colouring, and quaintness of appearance about them, that must, I think, strike every one who has not previously seen them. For myself, I know there is no richer treat in the whole floral year than a good look at collection of Auriculas, whether in my own garden or elsewhere.

I was hoping that the Auricula was about to take its place as an exhibition flower; but I turn to the schedules of the two great Societies, and alas! all my hopes are disappointed. The Royal Horticultural Society offers prizes for them on May 9th, if I read the schedule aright, while the Royal Botanic Society's Spring Show is fixed for March 21st. It would have been impossible to have fixed two dates which would more thoroughly exclude the flower than these. Of course there may be reasons, and sufficient ones, for these arrangements, but they are not the less to be deplored; while in the case of the Royal Horticultural Society it seems to be a piece of bad arrangement, for there is a Show to be held on April 18th, which is about the time they are in bloom. When the National Exhibition was held on April 30th, it was then found that for the southern growers it was all too late, and yet now they are expected to come forward on May 9th! What the result will be it will not be difficult to tell. In an immense collection like that of Mr. Turner, of Slough, there will, of course, always be found some in bloom at almost any time from the middle of March to the middle of May; but he, I venture to say, will be the only exhibitor. Amateurs will, I fear, be excluded altogether, and thus the encouragement given is now withdrawn.

It is these capricious alterations which do so much harm to floriculture. "Letting well alone" seems to be unknown in the arrangements of the schedules, and I have yet to learn that this constant state of change is conducive to good. If a thing works well why meddle with it? if badly, let it be altered.

Another thing I must as a clergyman protest against—the holding of the shows on Saturdays. It leads, and must lead, to a large amount of Sabbath-breaking for masters and men, and effectually excludes us who live at a distance from town from being present.—D., Deal.

HEDGES, AND SHRUBS SUITABLE FOR THEM.

(Continued from page 218.)

MAELURA AURANTIACA (Osage Orange).—The expectations formed ten or twelve years ago of this plant have certainly not been realised, and its hardness is not so well established as could be wished; for, although few plants of it may be killed by our most severe winters, still fewer escape altogether, as the tips of the shoots, being in a more or less unripened condition when winter sets in, are destroyed down to the firmer wood. The plant is also more straggling in its growth than the White-thorn, so extensively planted in this country, but its thorns are quite as formidable; its shoots likewise are very robust, and in summer the leaf is rather pretty. About ten years ago I saw a hedge of it planted by a gentleman well versed in new shrubs and trees; the hot, fine summers of 1858 and 1859 favoured the growth and ripening of the wood, great expectations were formed of it, and nurserymen advertised it as a plant for ordinary fences; but the trying season of 1860, so fatal to the expectations of those who were experimenting with semi-tropical plants, gave the death blow to their hopes of this, and it has not been much heard of since. As an ornamental plant it has little to recommend it, and when planted in shrubberies its only qualities seem to be the unpleasant remembrances it gives to those who unthinkingly approach too closely its formidable spines, while it sends its loose, straggling branches to a greater distance from its stem than is always noticed by those who have duties to perform amongst shrubs. By way of experiment the *Maclura* may be tried as a hedge plant, but it must not be classed as an ornamental one, and for utility it is unquestionably inferior to the Whitethorn.

ARBOR VITÆ.—This offers a marked contrast to the last, being an evergreen of compact and quick growth, which bears cutting. It also has the advantage of being perfectly hardy, bearing transplanting well even when it is of large size, and suffering little from breakages by the weight of snow, so destructive to other shrubs. The Chinese species (*Thuja orientalis*), is more compact in its growth than the American (*T. occidentalis*), and the kind known as *Thuja Warreana* is also of very close growth. As the Arbor Vitæ is often planted where a quick growth is required, large plants may be procured, and a hedge made at once. Dry ground, not too shallow, suits it best, but it is not particular, and good specimens may often be met with in a soil and situation just the reverse of those indicated. To look well this plant ought to be trimmed with the knife, and not with the shears, and excepting in certain special cases the top looks better not evenly cut, but as if in a growing state, with portions a little higher than others. August is a very good time to trim it.

BERBERIS DARWINII.—Although I have not seen this plant much used as a hedge, yet from my experience and observations of its growth, it seems well adapted for the purpose, and if it can be fairly established as a hedge plant, I know of nothing more desirable. A close, compact growth, with now and then a shoot or two running out 2 or 3 feet beyond the rest as if they were the pioneers of others, is its general character, and no plant presents a greater amount of foliage, every shoot being thickly studded with leaves, and these, too, of a pleasing bright green. Added to this, the handsome flowers which it presents us with early in spring claim for it a place in the front rank of flowering shrubs, almost equal to that of the *Rhododendron*, and in fine autumns it not unfrequently furnishes a supply of bloom as well. As a hedge plant it possesses the required sturdiness, and I believe will bear cutting as well as any other evergreen. It also produces berries in great abundance, the colour being much the same as in those of *B. aquifolium*, or as it is generally called, *Mahonia aquifolium*. The resemblance in fruit, though not by any means a close one, is the only resemblance the plants possess, the character of the

flower, size of foliage, and other features, giving *B. Darwinii* a stamp of its own unlike others of this remarkable family, with the exception of *B. Wallichii*. I therefore anticipate we shall often hear of its being used as a hedge plant, and so far as I have tried it, it promises to become a handsome and useful one. A dry soil abounding in stones seems to suit it best, but it is by no means fastidious, and with me grows twice as fast as *Mahonia aquifolium* in the same soils and situations.

IVY.—This is certainly not a hedge plant, I expect some one will say, and rightly, too, in one sense; but it forms an excellent screen, and when a sort of framework is put up of any reasonable height, and Ivy planted against it, there is nothing which so quickly effects the double purpose of a partial fence and screen; and as it is known that Ivy is not very particular as to situation, we have the further advantage of possessing in one of our finest-foliaged plants the means of speedily erecting a shelter, or shutting out anything ugly, whether in the distance or close at hand. The species and varieties of Ivy are numerous, and many are of great beauty, but the common Irish Ivy is, perhaps, unsurpassed for quick growth, general hardness, and the deep glossy line of its foliage. As plants of it are plentiful enough, I would advise any one who may be about clothing his premises with evergreens, to turn his attention to Ivy. It will accomplish its work sooner, and continue longer in the same condition than anything else I know. Apart from its beauty as a climber, some of its varieties are so dwarf that their yearly growth does not exceed that of the *Laurustinus*, or similar shrubs. Where, however, a series of arches or other framework is to be covered with Ivy, the low-growing variety is the best to plant, and few plants bear trimming so well, or continue so long in beauty—in fact, the death of Ivy, excepting from accident, is unusual. Although it does not possess the sturdiness necessary to support itself, I nevertheless regard its claim as a hedge plant too good to be overlooked.

WILLOW.—This certainly ought not to take its place amongst hedge plants destined for ornamental positions, yet I have seen it occupying a prominent place in a flower garden of no mean pretensions. The situation being an exposed one, and it being desirable to have some shelter at the earliest possible period, Willow poles about 2 inches in diameter at the top, and long enough to be 8 feet above the surface of the ground, were planted, about 18 inches apart, in a ditch or trench prepared for them. They speedily struck root, and formed branches from bottom to top, supplying a high hedge or screen in a very few weeks after being fixed in the ground. This afforded sufficient protection for the summer, which was all they were planted for. Willows, however, are sometimes planted for the more definite purpose of a fence, but they are only to be recommended in a wet, swampy place, where they thrive best, and where nothing else will do so well. Perhaps the best kind is that called the Plum-tree Willow, from its leaves resembling those of the Plum tree, as it furnishes itself best at bottom. Most of the tree Willows with lanceolate leaves become very naked at bottom, and must often be headed-down. By the sides of ditches or ponds, or in very wet places, the Willow may be planted as a fence, and by frequent cutting-down and plashing, it may be made serviceable, but it cannot be said to be ornamental.

ELDER.—This is worse than the Willow, so far as appearance is concerned, and it has not the advantage of growing where other and more ornamental plants will not thrive, but it grows faster than anything else, and it has the merit of not being attacked by rabbits in places where these abound. The Elder will also sustain itself when competing with other trees and shrubs, and, in fact, is more likely to outgrow and overtop everything else than succumb to opposition. As a plant for a hedge, however, its merits are of a low order, and it is only mentioned here as some writers have a partiality for it. An old plant in flower looks very well, but no amount of trimming can make a graceful hedge or fence of this offensively-smelling tree.

FURZE OR GORSE.—Although of indigenous growth this plant now and then suffers from severe winters, and when planted as a hedge it does not bear clipping and trimming so well as many others. It is seldom advisable to plant it as a fence, unless for some special purpose, when its appearance is desirable, as it requires to be allowed more width than other plants, and looks better as an irregular mass than in a trimmed condition; indeed, the latter cannot well be maintained long. For a very exposed stony soil it may be necessary to try this plant, but where others will succeed, let this be banished to its proper quarters—viz., wastes and coverts. The double-flowering Furze, and the upright Irish variety, are,

nevertheless, ornamental; and deserving a place in most shrubberies.

HAZEL AND MAPLE.—Often found in old hedges that appear to have been formed out of the natural growth of the place, but neither desirable to have as a hedge plant. They have the merit of thriving in most soils; and the Hazel, especially, presents a close, compact bush, not easily penetrated by cattle. It is certain, however, that the advanced cultivation of the country is fast driving these plants from their established abodes, and but few, indeed, are planted. As we possess much better hedge plants than either, their removal will be no loss.

—J. ROBSON.

(To be continued.)

PROPAGATING AUCUBA JAPONICA.

A FEW remarks on the *Aucuba japonica* may, perhaps, be useful to some of your readers.

In September, 1864, I bought two small plants of *Aucuba japonica* vera, and planted them out at once. They both flowered in the spring of 1866, and with pollen gathered from them I impregnated a large plant of the common variety; the result was several dozens of berries, which were green and unripe on the plant during the severe frost in January, 1867, when the thermometer was below zero. Notwithstanding this, the berries ripened well, and changed to bright scarlet three or four weeks afterwards. I know that they were quite ripe, because I sowed the berries on the 28th of March in a pot containing sandy loam mixed with a small portion of peat, and every one of them germinated. I placed the pot in a shady part of the plant stove, but it was from three to six months before the young plants made their appearance. They are now fine little plants, and have just been potted-off singly into 60-sized pots. They nearly all partake of the character of the male plant, only one of them being spotted like the female.

In March and April, 1867, there were a great many blossoms on the two male plants. I therefore prepared a dozen small plants of the common *Aucuba* in various sized pots. These I placed in the orchard house, and as the flowers expanded I dusted them with pollen. My mode of proceeding is with a pair of Grape scissors to clip off the male blossoms, letting them fall on a small sheet of clean paper, and to convey them at once to the spot where the plants intended to be operated on are placed. One male blossom will dust from four to six of the others. Some of these small plants in pots are now very pretty objects, and have been a distinct feature in the greenhouse for the last two or three months. They look as well as ever at the present moment. One neat little plant in a 7-inch pot has 120 of these large bright scarlet berries on it, and several of the others have nearly as many. One large plant growing out of doors, which was also operated upon artificially, is covered with clusters of the berries.

I cover the male plants with glass as soon as the first flowers expand, as they are growing in a very exposed position, and are liable to be very much damaged by the wind and rain; but notwithstanding this precaution, and the fact that I cut the flowers off as fast as they expand, nearly every female plant in the garden has a few berries on it. The bees, I have no doubt, found their way under the glass covering, which is raised on bricks in order that the air may play freely round the plants. The greatest distance from the male plants at which I found berries was 180 yards, so that I have no doubt when plants of the male *Aucuba* become more numerous, berries will be common enough everywhere through the agency of the bees.—J. DOUGLAS.

MESSRS. CUTBUSH'S SHOW OF SPRING FLOWERS

AT THE ROYAL BOTANIC SOCIETY'S GARDENS.

This commenced on Saturday, will continue throughout the present week, and is altogether an excellent display, the extent of which will be judged from the fact that it fills a span-roofed tent adjoining the conservatory 150 feet in length and 16 feet in width. There is a 10-foot path up the centre, over which are suspended baskets of flowers, and on the side next the conservatory there is a stage with a row of Tulips in front, and a row of Hyacinths at back. Opposite this is a mixed bank of Camellias, Azaleas, Heaths, Epacris, Cinerarias, Cytisus, Crocuses, Narcissus, Lily of the Valley, Cyclamens, double *Prunus sinensis*, and other flowering plants, interspersed with a few *Draenas*, *Indiarubber* plants, and other subjects ornamental by their foliage; and at one end is a similar bank, whilst at the other

there is a plant of *Cyathia dealbata*, flanked by two quarter-circle wire flower stands.

Of the quality of the Hyacinths and Tulips which are the real objects of the display, the other plants being merely the adjuncts, the success which Messrs. Cutbush have achieved, both in the present and past years at the London and Liverpool shows, is a sufficient guarantee; in fact, many of the pots were in the collections shown at these exhibitions this year.

Of Hyacinths we remarked magnificent spikes of Baron Von Tuyl, Haydn, Marie, Mimosa, Charles Dickens, Von Schiller, Princess Clothilde, Macaulay, General Havelock, Grand Lilas, Gigantea, double Duke of Wellington, Van Speyk, and Mont Blanc. Of Tulips there are fine pots of Vermilion Brilliant, a most effective variety; Keizerskroon, Rex Raborum, Pottbakker of different colours, double Tournesol, and Couleur Cardinal, all of which are well known; Proserpine, rose; Brutus broken, red and yellow, very fine; Cottage Maid, white and pink; Chrysolora, yellow; Fabiola, white and rosy purple; Van der Neer, purplish violet; Thomas Moore, coppery orange; and Duchesse de Parma, deep crimson edged with yellow.

The conservatory itself also presents a gayer appearance than usual. Rhododendron arboreum and Camellias being covered with flowers, in addition to which there are Azaleas, fruiting *Aucubas*, *Cinerarias*, and various flowering plants. One large vase is very effective, being filled as follows:—Outer circle, Amy Hyacinth, red; second circle, Staten General, white; third circle, Lord Nelson, blue; then there is a double row of Grand Monarque Narcissus, with *Calla aethiopica* in the centre.

COCKSCOMB CULTURE.

I FIND great difficulty in getting seed of those which really produce fine combs. A neighbouring gardener grows them exceedingly well, and has a fine strain. I have just procured a little seed from him, and have sent a portion of it to the continent to be grown, hoping thus to obtain a good supply; and as I shall visit the country where it is grown during the summer, I shall see how it is doing then.

Mr. John Burnell, the gardener I have referred to, writes—“I have tried many plans to grow them well, and the best mode which I have found for growing dwarf and large Cockscombs is, to pot them from the seed pan into 60-sized pots, grow the plants in these until the combs are well formed, and then repot.”—WILLIAM DEAN, *Bradford Nursery, Shipley*.

NEW GLASS STRUCTURES FOR GROWING FRUIT.

SOME twenty years since, no difficulty was experienced in growing Peaches and Nectarines on outside walls, and I can recollect thirty years ago it was not at all unusual for a bushel of this fruit to be picked at a time in one of our gardens. Now these trees begin to decay after a few years, and, gradually dying away, require to be constantly renewed. They seem to have no constitutional strength. What is the cause of this? and is there no remedy, for it is a general complaint? Cannot we learn something from the management of these trees in the orchard house, where they invariably set their fruit, ripen it thoroughly, and do not die away? I have a house, 72 feet by 30 feet, in which the trees have borne excellent crops of fruit for the last eight years. These trees, forty-five in number, are planted in the soil, which is hard, and seldom receives any manure. They are watered occasionally, when a good drenching is given from a hose with a pressure of 50 feet. The pruning takes up about as much time as the training of a large tree on a wall. This, with the painting the trees in the autumn with Pooley's tobacco powder and methylated spirits, embraces the whole treatment. The crop keeps the trees from too luxuriant growth. Every tree is now in full bloom, and will bear a large crop. Twenty dozen of Peaches (Royal George) were gathered from one tree.

I have tried for several years to grow Plums and Apricots in the same manner, but having never succeeded, was obliged to give it up. I can grow large crops of this fruit in pots, but not in the soil. I have therefore had recourse to a plan I conceived some years since, which has more than answered my expectations. I also tried experiments last year with Peaches on the same system, and found that it answered equally well with them. I have now twenty-three Peach, Nectarine, Plum, and Apricot trees under experiment. They are now in bloom, though out of doors. They are surrounded with glass walls, open at the top, if we except a woollen net to keep off frost, and, in the autumn, insects.

Formerly, we used to consider Peaches and Nectarines as hardy. Now, I think we must consider them as only half-

hardy, and if so we must adopt a less rude treatment than in former years. A wall heated while the sun shines on it, and a wall rendered cold by wind and evaporation when the sun is off, does not seem to suit these now tender plants; neither does too great an amount of moisture to the roots, especially in autumn, agree with their delicate constitutions. Cold, moisture-absorbing winds cause a chill. Bringing the trees in too close contact with walls by nailing cripples them, and lowers their temperature to that of the wall, especially a stone wall. All these difficulties may now be overcome by very simple means, and probably we shall again be able to grow these fruits for ten years to come in the same perfection as formerly, by which time we may be obliged to introduce some other method if these plants become gradually more tender.—OBSERVER.

FLOWERS LOVELY, THOUGH COMMON.

I wish that those who grow only bedding-out plants because they desire "masses of colour," and so for the sake of a blaze of blossom during five months are content to have bare earth to look at during the other seven, could see my little flower bed for March this year. It has five rows of plants:—

1. In front, near the Box edge, are patches of Snowdrops, yellow Crocuses, dark and light purple Crocuses.

2. Behind these follow Dog's-tooth Violets, white and purple, of which it is hard to say whether the blossom or the leaf is the more beautiful, varied with groups of the tiny dwarf Daffodil, interspersed with that most valuable early white Hyacinth, now in full bloom, but of which I do not know the distinctive name.

3. Then follow Primroses, single and double, of various colours, making a very gay and effective row, with clumps of blue and white Squills at intervals.

4. Next, Hepaticas, white, pink, and blue, with bunches of *Orobis vernus*, a plant too little known, and Venus's Navelwort with its Forget-me-not-like bright blue flowers.

5. Lastly, in my back row come *Daphne mezereum*, Christmas Rose, still in bloom, and *Saxifraga crassifolia*, with *Jasminum nudiflorum* here and there on the stems of some fruit trees, and a few pink Ribes, now sheets of blossom to the great delight of my bees.

It would be hard, indeed, with any amount of bedding-out plants to produce anything more effective than this bed has been on all our bright days; its value, too, increased tenfold by its heralding to us the approach of summer, and gladdening us now at a time when flowers are generally scarce. When I add to all this the intense pleasure which it has been to me for weeks past, day after day, to see one after another of these, my favourites, peeping above the ground—sometimes, perhaps, helped by my own hand when I am tempted to look for my old friends in their accustomed places, and to remove the too heavy superincumbent lumps of our ungenial clay—I confess that I am at a loss to account for the apathy of so many to all but those plants which are grown by thousands under shelter through the winter, and bedded-out by the gardener in June.

Our old English perennials will, if carefully selected, afford the colour so much desired, and when not in blossom the plants themselves will always at every period of the year be a source of real pleasure and interest to any true lover of gardening and of flowers.

I have given in this letter an idea of what may be done in March. Possibly, if you think well to grant me space, I may send you an account of my April flower bed hereafter.—W. J. MELLISH, *Orston Vicarage, Notts.*

[We will grant the space, and we wish that many such communications reached us, "there's heart in his purpose."—EDS.]

THE INNER TEMPLE GARDENS.—Mr. Broome has just now three Leicester vases and a score of small beds filled with about five hundred Hyacinths, which, though not yet in perfection, nevertheless promise to be most satisfactory for an out-door London garden. In addition to the Hyacinths there are Crocuses now in very good bloom, Tulips to succeed the Hyacinths, and Virginian Stocks and other early-flowering annuals to furnish a further succession, and which are now just above ground. These will give place to bedding plants which, in turn, will be succeeded by Chrysanthemums, carrying on the succession of bloom to Christmas. Mr. Broome plants his Hyacinths in October in cocoa-nut fibre refuse, under a west-aspect wall,

removes them in January, either by hand or with a hand-fork, taking care not to break the roots, and plants them in the decayed refuse.

WOODEN-FRAMED HAND-LIGHTS.

Is it generally known carpenters can make very serviceable hand-lights for all general purposes about a garden? It is well known that hand-lights are in general made of cast iron; this renders them very heavy. One of the objections which some have to using cast-iron hand-lights is their very great liability to be affected by the weather; in hot days when the sun is powerful they become very hot, and in frosty weather the reverse takes place.

What I would recommend may be used for nearly all the purposes to which cast-iron hand-lights are applied. Any carpenter can make for a hand light a wooden frame 1 foot 9 inches long by 15 inches wide, or 2 feet long by 18 inches wide, and from 6 to 8 inches deep at the sides, having a spau-shaped roof rising to 16 or 18 inches high. Let a tolerably stout piece be employed to pass between the tops of the ends or gables; and if one piece of glass be objected to as being used on each side, let one or more ribs be used, nailing them under the upper ridge of wood. As I have already remarked, this ridge of wood ought to be tolerably strong, as it has to bear the handle which lifts the whole light when made. Fig. 1 represents the end of one of these very useful hand-lights; fig. 2 is a side view, having the handle by which the light is lifted.

For many purposes, especially during winter, these lights are very useful, as for placing over Cauliflowers in any convenient place, or many other things which are the better of

slight protection. The glass in these is not so liable to be cracked by frost as in the cast-iron hand-glasses. In order to give air to plants under them, I place a brickbat or knob of wood the size of the clenched fist close by them; and thus by only moving the light 1 inch backwards or forwards I have it either off or on the brickbat. They will be found not to be half the price of the cast-iron hand-lights; this in itself is a consideration with most people.—G. Dawson.

LOBELIA SPECIOSA AS A DECORATIVE PLANT.

It may surprise some and interest others to know in what manner this plant is so, but not for summer garden decoration; nevertheless, when it is grown well it is a most splendid plant for early spring conservatory decoration. My employer is very fond of it as a table ornamental plant, and most graceful it is for the purpose.

It is very easily grown, and requires but little attention. I have it in bloom about seven months in the year, and I find, more especially towards the summer, when blue is rather scarce in-doors, that it greatly enhances the in-door decoration.

I only bring this under notice that some who may not have tried it may venture on a pot or two, and I am sure they will not repent of the little time and labour devoted to it. Plants in a 32-sized pot, and covered with bloom all round and to a depth of 2 feet or more, will well reward any one.—NEMO.

CHECK TO THE SLUG AND TURNIP FLY.

A LITTLE gnatow sown broadcast over the surface kills or banishes slugs. It is equally effective against the Turnip fly if sown on the surface at the rate of 2½ cwt. per acre. It answers a double purpose, for it not only keeps away the fly, but serves as a top-dressing. Its effects were proved here last

year on a piece of Turnips. Part being treated in the way I have described was a good crop, but the part not so treated was completely eaten up by the Turnip fly.—C. J., *Acley*.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

THUNIA BENSONII (Mrs. Benson's Thunia). *Nat. ord.*, Orchidaceæ. *Limn.*, Gynandria Monandria.—Native of Rangoon. Flowers purplish lilac and white. Lip darker purplish lilac, with yellow-crested disk.—(*Bot. Mag.*, t. 5694.)

BEGONIA GLANDULIFERA (Glandular Begonia). *Nat. ord.*, Begoniaceæ. *Limn.*, Monoclia Polandria.—Native of Trinidad. Flowers white.—(*Ibid.*, t. 5695.)

DICENTRANTHERA MACROPHYLLA (Large-leaved Dicentrantthera). *Nat. ord.*, Acanthaceæ. *Limn.*, Didymia Angiospermia.—Native of Fernando Po, and banks of rivers in Western Africa. Flowers rosy purple externally, whiter internally.—(*Ibid.*, t. 5696.)

ODONTOGLOSSUM ALEXANDREI var. **GUTTATUM** (Spotted variety of Princess Alexandra's Odontoglossum). *Nat. ord.*, Orchidaceæ. *Limn.*, Gynandria Monandria.—Flowers white spotted with dull crimson; lip yellow at the base.—(*Ibid.*, t. 5697.)

VERNONIA (STENGELIA) CALVOANA (Signor Calvo's Vernonia). *Nat. ord.*, Composite. *Limn.*, Syngenesia inapalis.—“This magnificent composite plant” is a native of the Cameroons Mountains, in the Bight of Benin, at 7000 feet elevation. Ray florets and involucre scales white; disk florets purple.—(*Ibid.*, t. 5698.)

COLA ACUMINATA (Kola-nut Tree). *Nat. ord.*, Sterculiaceæ. *Limn.*, Monoclia Monadelphia.—Native of Tropical Africa. The nuts are universally eaten by the natives there, and in the West Indies, as a condiment. They are also used as a medicine, and to sweeten putrid water. Flowers yellow.—(*Ibid.*, t. 5699.)

PELAGONIUM. *Andrew Henderson*.—“Submitted last autumn to the Imperial Horticultural Society of France, and awarded a first-class certificate for its superlative merit, this very beautiful double-flowered variety of Zonal Pelargonium, may well commend itself to our notice. M. Carrière in advertising to it, remarks that, had the raiser flowered it soon enough to have been able to exhibit it at the Great Paris Exhibition, it would have been universally admitted to be greatly superior to all other known varieties in its class.

“One of its chief features of excellence consists in its style of growth, the habit and texture of foliage being more like those of the majority of the fine single-flowered varieties of English gardens, than of the robust, coarse, vigorous double sorts of the *P. inquinans* section, previously known. The colour of the flowers also differs from that of all preceding varieties, being a clear deep scarlet lake. The truss is of extraordinary size, larger than in any previous double variety, taking a globular outline, and bearing from sixty to eighty expanded blossoms, which are well proportioned, very double, and regularly imbricated like a *Ranunculus*, thus again differing from the sorts already known, which more nearly resemble the *Hollyhock* in the arrangement of their petals.

“This brief description sufficiently indicates the distinguishing features as well as the great merit of this novel variety, which we may safely recommend for conservatory pot-culture, and also to form select specimens for garden decoration. The variety was raised by M. Lemoine, of Nancy, and a great portion of the stock has been acquired by Messrs. E. G. Henderson & Son.”—(*Florist and Pomologist*, 3 s., 1, 19.)

EMIGRATION.

The communication in the *Journal* of the 20th ult., from a correspondent in New Jersey, calls for comment. He endeavours to argue that “*WILTSHIRE RECTOR*” is wrong in teaching contentment, and attempting to dissuade his countrymen, and those of them who are gardeners or garden labourers in particular, from leaving a certainty in their own favoured land for an uncertainty in a new and strange country, and goes on to show the advantages to be obtained by a residence in the United States. He states that his labourers each receive 1 dol. 60c. per day for their work, which if they were every day employed would amount to 9 dols. and 60c. per week, and if they paid 5 dols. a-week for board and lodging, there would be left a balance of 4 dols. and 60c. with which to provide clothing

and other necessities. Now, how far will this go even with an unmarried man, when a respectable suit of clothes, such as an English gardener would like to appear in, will cost from 10 to 50 dols., and a good pair of boots 8 or 10 dols.? Then, again, the cost of provisions is enormously high, and, if necessary, I could give a list of prices which will prove that fact, and show that the cost of living is proportionably greater than in England.

The fact of the shipment of broadstuffs, &c., from New York to England is no argument at all. There is a surplus of Wheat, flour, cheese, &c., in the country that could not be disposed of at any price at home, and must be exported for a market. Most of these productions come from the Western States and Canada, and when the cost of production and the price received are taken into account, it will be found that there is very little for the producer, and that the railway and other carriers obtain most of the profits.

I have warned “gardeners by profession,” of the vicissitudes of the climate in the temperate parts of North America, and your correspondent's story tends to prove me right. Although “John,” judging from his vernacular, must have been a very poor specimen of the professional, yet we cannot believe that his “flowers” came to grief altogether through his inexperience and negligence. They were a total failure, and as the master seems to have supplied the plants it must be presumed the “sort” was all right, and the season must have had some effect on both the “flowers” and the Cabbages. If this be not the case, then gardening in America must require a vast deal of American experience.

At the present time the United States is a tax-ridden country. Even a halfpenny bunch of matches is pasted over with an internal revenue stamp of the same value as the matches. Then it must be remembered that little or no work can be done in the winter, and a labouring man must lay up enough of his summer earnings to provide for him during the unemployed days of winter. I know a hardworking industrious old man, and a good kitchen gardener, who has been in business for himself in America for some years, and who has often told me that while working in a nursery near Exeter for 9s. per week he was better off and much happier than he has ever been in his adopted country, as the winter always eats up all he can lay by during the growing season.

After a residence of eighteen years in foreign lands, and much of the time spent in various parts of North America, I say most emphatically, *Stay at home*, and as a pendant to this advice would add the following extract from the *London Scotsman*, and say that not only ironmoulders to whom it particularly refers, but all others, and especially the members of the “*Journal*” circle, will be more happy and prosperous if they take good “*WILTSHIRE RECTOR*’s” advice.—W. T. GOLDSMITH.

“CAUTION TO PURPOSED EMIGRANTS.—The sanguine promises of plenty of work and high wages in America, held out to members of the Scottish Ironmoulders’ Society a few months ago, have not been realised. Three members of the union, who went to the United States last November in the hope of finding plenty of work, have sent home a melancholy warning to their comrades, in which they state that they have been ten weeks in Pennsylvania and ‘have not yet found a lion’s work.’ They complain in very severe terms of the officers of both Scotch and English societies ‘for withholding information relating to trade in America.’ The member at home, they say, ‘have been continually kept in the dark. All kinds of work are equally scarce; we are nothing but starvation before us, and hundreds of our fellow-moulders who have come here as we did, are in a like, or even worse condition.’ The President of an Ironmoulders’ Union in Philadelphia corroborates the statement of the unfortunate Scottish emigrants. ‘Fully three-fourths of the entire labouring population of the States are now out of work,’ he says, ‘and there seems to be no prospect of improvement. He denounces the emigration scheme promoted by the officers of the English and Scotch trades’ unions as a ‘direct outrageous fraud’ practised upon their own members, and a gross imposition upon the American people. If the leaders of trade societies can make no reply to this, they ought to be severely punished in some way or other.”

ORNAMENTAL AND FLOWERING SHRUBS.

(Continued from page 204.)

DRYAS REZARUM.—Flowers pink, small, numerous, sweet-scented, appearing before the leaves. January to March. 3 to 4 feet. Seeds. A well-known and highly ornamental shrub. There is a variety with white flowers.

DRYAS CRENATA HOGG-ELLING. — Flowers white, double, highly ornamental, in May and June. Cuttings and layers. 2 to 3 feet.

DRYAS GRACILIS.—Flowers white, in clusters, very handsome, and

very profuse-blooming. 2 feet. Cuttings and layers. One of the very best shrubs for forcing.

DEUTZIA SCABRA.—Flowers whitish, in clusters, in May and June. Succeeds in shade, and is of quick growth. 6 feet. Cuttings and layers.

DIERVILLA CANADENSIS.—Flowers yellow, small, June to September; leaves shining. 3 feet. Suckers, layers, cuttings, and seeds.

EGONYPUS LATIFOLIUS.—Flowers green, succeeded by red fruit ripening at the end of summer, and which are its chief attraction. 10 feet. Seeds, cuttings, and layers.

FORSYTHIA VIRIDISSIMA.—Flowers yellow, appearing before the leaves, which are dark green. It flowers from February to May. 6 to 8 feet. Cuttings and layers.

HALESA TETRAPTYCH (Snowdrop tree).—Flowers white, drooping, small but numerous. 8 to 10 feet. Suckers, layers, and cuttings of the roots.

HAMAMELIS VIRGINICA.—Flowers yellow, profusely produced in autumn and winter. 10 feet. Layers.

HALIMODENDRON ARGENTEUM.—Flowers purplish, from May to July; leaves white and silky, the shoots being spiny and grey. Grafted on the Laburnum, it forms a neat head. 6 feet.

HEPHERAE RHAMNIFOLIA.—Flowers apetalous, succeeded by numerous orange berries. It succeeds admirably planted near the sea. 8 to 12 feet. Layers, suckers, and cuttings.

HIBISCUS SYRIACUS (*Althæa frutex*).—Flowers large, single or double, and in different varieties, white, red, purple, or striped. They appear in August and September, and are very showy. 6 feet. Layers, and seeds of the single varieties sown in heat, the seedlings being well hardened-off.

HYDRANGEA HORTENSIS.—Flowers in large dense heads, pink changing to blue, and sometimes blue. June to August. 3 to 5 feet. Should have a sheltered situation, and light rich soil well supplied with water during the growing season. Cuttings and layers.

HYDRANGEA QUERCIFOLIA.—Flowers white, in dense clusters in summer. 5 feet. Cuttings and layers.

KERRIA JAPONICA.—Flowers yellow, very profusely produced in spring and early summer. The double variety is that most generally cultivated, and is very ornamental. 6 feet. Suckers and cuttings.

JASMINUM FRUTICANS.—Flowers yellow, small but numerous, June to September. It requires a warm sheltered situation and a dry soil, otherwise it does not succeed. 6 feet. Suckers and layers.

LEUCOSTEREA FLORENS.—Flowers purplish, in June, succeeded by purple berries. It requires a warm situation. 6 feet. Cuttings in slight heat or under a hand-glass, also seeds in heat.

LONGICHA TATARICA.—Flowers reddish, in April and May. It thrives well under trees. Cuttings and seeds.

LONGICHA ILERICA.—Flowers orange, in May. 6 feet.

LONGICHA PYCNANTHA.—Flowers white, in May. 6 feet to 8 feet.

LONGICHA XANTHOPHYLLA.—Flowers yellow, in May and June. 6 feet to 8 feet.

All the shrubby Honeysuckles thrive under trees, but not in deep shade.

LIGUSTRUM VULGARE.—(Common Privet).—Flowers white. Very valuable for planting under trees, for hedges, and as a screen. 6 to 10 feet. Cuttings and seeds.

MYRTICA GALE (Sweet Gale).—Red catkins in May; leaves oblong and sprinkled with yellow dots. Where the *Rhododendron* grows this will thrive, otherwise it requires a peat soil. Layers, cuttings, and suckers. 4 feet.

PAVIA DISCOLOR.—Flowers large, yellow and purple, in June. 6 to 8 feet. Grafting on the Horse Chestnut.

PAVIA MACROSTACHYA.—Flowers white, sweet-scented, in July and August. Thrives in a shady situation, and does well in moist ground, hence it is very suitable for planting near ponds and sheets of water. 8 to 10 feet. Layers.—G. ARBELY.

(To be continued.)

PHALENOPSIS SCHILLERIANA.

THROUGH the courtesy of Mr. Robert Warner, of Broomfield, near Chelmsford, we have been permitted to see the finest collection of *Phal. nopsis Schilleriana* in bloom that exists anywhere out of their native region. Rare as the plant is, Mr. Warner can show no less than forty-two fine specimens, some of which are hitherto unrivalled in this country. It is gratifying to have to state that Mr. Warner is sufficiently generous not to reserve the pleasure entirely to himself, but is willing to share the privilege of admiring to all who are interested in their culture.

WORK FOR THE WEEK.

KITCHEN GARDEN.

It is advisable to run the hoe over every part of the kitchen garden and slips whenever the ground is in good condition for the work. *Asparagus*, the beds should now have their spring dressing, if not yet finished; fork them over slightly, and rake

the soil even. Cut and trim the edges of the beds. *Artichokes*, if not yet done, lose no time in giving them their spring dressing; thin out the suckers, dig in a good quantity of dung among them, and plant a few rows of the spare suckers to succeed the general crop. *Broccoli*, a few seeds of Grange's Early should now be sown. *Cabbage*, continue to sow a few early sorts every fortnight. *Peas and Beans*, go on with successions of these every other week. *Potatoes*, in many parts of the country people put off planting their Potatoes until too late; the whole crop should be in before the middle of the month, and the sooner the better. *Endive*, where the last autumn-sown plants have stood the winter they will now require to be tied up in succession, like Lettuces, to blanch; they will come in very useful with the early Lettuces, a few of which should also be tied up if they are opening too much in the heart. *Chives*, no garden should be without this useful little plant; a row of it planted along an alley, will be a substitute for young Onions all the year round. *Onions* sown last August should have the soil well stirred between the rows; let one bed of these Onions remain to be drawn before the spring-sown Onions come in, and transplant the rest. *Spinach*, the August-sown should have the soil well stirred between the rows.

FRUIT GARDEN.

Run the hoe between the Strawberry rows, or if the ground was dug early in winter, you had better stir it with a fork. Hoe also between the Raspberries, Currants, and Gooseberries, if only to loosen the surface of the ground. Watch carefully the state of the weather while the Peaches and Apricots are in blossom.

FLOWER GARDEN.

The weather has been so mild, that we appear almost on the verge of summer before the spring has fairly commenced. All new ground work, such as planting, turfing, &c., must be finished as expeditiously as possible, and as soon as all rubbish has been cleared from the borders, grass, &c., prepare for turning the walks, and making all clean for the season. This, though an operation readily performed, is frequently hurried over, and badly executed. A walk after it has been turned, leached, and a facing of new gravel laid upon it, should remain in that state three or four days for the gravel to bleach, and not be rolled until it has had a shower of rain upon it. The utility of this plan is, the gravel becomes washed before it is rolled down, and a clean bright walk at all times is obtained, instead of one sticking to the feet, and falling into holes in wet weather. This delay causes a little inconvenience for a time, but it is fully counterbalanced by the excellence of the walks throughout the season. Birds are very troublesome to newly-germinating seeds, and where it is inconvenient to cover with netting, it will be well to sprinkle the beds with sand made wet with spirits of tar. The transplanting of all autumn-sown annuals should be completed without delay, also of biennials. Prepare for a sowing of the latter a piece of ground which must be slightly enriched and dug to a good depth. Amongst shrubs the work for the season will be finished, except attending to those newly planted, and watering them when necessary. Take care that all newly-planted trees are properly staked before they begin to make new roots, and mulch them with short grass occasionally when the lawn is mown. The flowers of Auriculas are putting on an improved appearance, still keep the plants warm at night by mat coverings, and as they are growing fast they should have a moderate supply of water. The potting of Carnations has commenced in many parts of the country, and when the plants have been brought up hardy, the sooner they are out the better. As a precaution, place a slice of potato between the layers, if two are planted in a pot, so that they may have a chance of escaping destruction, should a solitary wireworm be in the soil.

GREENHOUSE AND CONSERVATORY.

To keep the conservatory now in proper order you must go over the plants daily, or at least every other day, and take out such as are beginning to fail. Pick off all dying flowers and leaves, and also distorted flower buds, or, indeed, any small or ill-arranged flower which does not look well. Change the plants in sitting-rooms often. If they are worth preserving afterwards, see that the more common sorts of plants brought in merely for their flowers or fragrance do not crowd on the good specimen plants. Azaleas, and many other plants, are now making their young growth, and if choked up with a profusion of forced plants of little value save for their flowers, it will soon injure them. It may be necessary soon to use blinds to guard the flowers from strong sunshine, but this should be deferred as

long as possible. Fuchsias represent that class of greenhouse plants which do best to be shaken out of their pots annually, but as the strong varieties of them are gross feeders, you may use a rougher compost for them than is recommended below for stove plants under the same treatment. A few of the smaller plants of the common Cacti may be now forced to make an early growth, this will enable them to flower early next spring. Potting and propagation, with a more liberal supply of water and less air, must be attended to.

STOVE.

In potting stove and other plants a distinction should be made between the preparation of the composts for permanent woody plants, and for those softwooded kinds which are annually shaken out of pots. *Justicias*, *Vineas*, and some of the *Clerodendrons*, form part of the latter class. After these are done flowering in autumn, they should be close-pruned, and left partially dry during winter. In spring the soil should be shaken from their roots when they are put into small pots, to be shifted into larger ones as they advance. The compost for this potting should be made quite fine, in order to let the roots occupy every particle of it in a few months, while the compost for permanent woody plants can hardly be too rough.

PITS AND FRAMES.

The bloom of the *Hydrangeas* introduced into the forcing house in January will now be advancing; if you have any doubt of its being blue, water the plants regularly with water impregnated with alum to the extent of 1 oz. to every quart, and keep the plants standing in feeders or saucers to prevent the loss of water. Brompton Stocks in pots, may be planted out, surrounding the ball with rich soil, and spring-flowering Ten-week varieties may be left unprotected, so as to prepare them for bedding-out about the middle or end of April.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Onions.—Sowed the last of the main crop in rows, covering the seeds with light soil riddled, from beneath the potting-bench; trod slightly in, and levelled by raking in the same direction as the rows. The ground is still rather heavy and damp for rolling, but as soon as it is dry enough we will run a light roller over it. We find it a good plan to do this just as the seedlings begin to appear. This secures a firm surface, and then a slight hoeing between the rows does not interfere with the general firmness, whilst it keeps the ground cool and prevents its cracking with fierce sun heat.

Carrots.—Sowed some out of doors, but the chief work as respects them has been preparing the ground by frequently turning it. The same remark applies to Beet, Salsafy, and Scorzonera.

Peas.—Sowed successions, planted out what had been reared under protection, placing laurel twigs on each side to keep them warm, and staking as the work proceeded. We have been obliged to net those coming through the ground out of doors, to preserve them from various intruders. The covering of root kept away mice, &c., until the seedlings began to appear. The dwarf Peas in pots in the orchard house must have a few little twigs stuck round them the first wet day.

Sowed Spinach, Radishes, Lettuces, and Turnips, the last in the open air and also under protection. When Turnips are wanted early they should be sown under glass and over a slight hotbed in the beginning of the month. One reason why they require protection when sown early is, that the frost will not greatly injure the appearance of the plants, but it will cause them to bolt, and then farewell to a crisp, succulent Turnip.

Potatoes.—From want of material at the time we could not give any bottom heat to our earth pit, which we planted some time ago, and owing to a deficiency of sun heat to warm the soil, the crop will not be so early as we expected. We have, therefore, planted two or three frames having a mild heat below them with good plants from pots, and also some taken up with balls from a Mushroom house, which will come in soon and succeed those grown in pots. Before this shall have been printed we shall also plant at the foot of the walls, and in well-pulverised borders those thus set growing in the Mushroom house, as much experience and observation testify that plants thus started and rooted will come in weeks earlier than those planted without that preparation. The sets are placed on old Mushroom dung and leaf mould, and covered about an inch, and the planting should take place when the tops are not more than an inch above the covering. If the sets be placed 3 or 4

or more inches apart they may be lifted with a mass of roots imbedded in the rough material, and if the day is sunny and the warm surface soil is placed round the roots, they will receive no greater check than will predispose them to tuber more quickly. We see the first-planted by the side of a wall are coming through strongly and well.

Celery.—Made up a bed, which will have temporary protection, in which to plant out what was previously pricked out from the seed pot. In a week or so will sow on a slight hotbed Celery and Cauliflower, the latter being pricked out before the former attains any size. The bed which we will use for planting-out the nice little plants of Celery, consists of 15 inches of dung and leaves, then of 3 inches of rotten dung and rough mould, and was finished with 2 inches of fine light soil in which to plant about 4 inches apart. From this place the plants will be lifted with balls at planting time. This bed will be covered with sashes for a few weeks, taken from a frame filled with Lettuces in use, and as these are outside the garden, we protect with nets to keep off marauders. There is just now a fine lot of Lettuces in the coldest orchard house. Were we disposed to take up market-gardening, we could easily see to what uses these cheap houses could be devoted in securing early vegetables. We question if even then cold places in the north might not vie with the south and the Channel Islands, and the south of France, or even Algeria, for the carriage from thence must cost something, and, therefore, would tell as a percentage on the cost of glass. As it is, unless with early-forced crops, the foreign and southern growers must have it all their own way, as Potatoes, Rhubarb, &c., come into the northern markets before they are more than above ground in these neighbourhoods. In general the first importations of new Potatoes are poor in flavour; but still, being new Potatoes, they are a boon and a change to those who cannot have them of home growth.

Sea-kale.—Planted a piece after duly trenching, airing, and enriching the ground. As we grow chiefly to lift for forcing, and to cut from the open ground with the help of a pot or a box over the plants, we grow them chiefly in rows 2 feet apart, and the plants 1 foot apart in the row. Seedlings of last year planted now make strong crowns for next season, and if these are cut that year, and three or four shoots left, they will be strong heads for lifting for forcing the season following. We like young plants best, but cuttings from the bottoms of the roots, if 6 inches long and as thick as the little finger, make excellent plants, but come in later. The top end should be just above the level of the soil, and when the concealed buds there break, it will be necessary to thin them if more than two or three come. Last season we did not obtain any seed. We never like to have too much as it injures the plants for making fine buds for the following year, but we generally leave a piece which we do not intend to use until it has had another summer's growth, but last season as soon as a seed pod began to become a little firm it was pounced on and devoured by the rats. We noticed a fact new to us the other morning, which explained to us what we had found next to inexplicable—how rats could flourish in large settlements at a great distance from water. In the neighbourhood of some wheat stacks we could count a score or more rats quietly sipping the dew that rested on young Clover and other plants, so that they were thus saved the trouble of taking a long journey in search of a drink.

Sea-kale at this season may be had very fine if covered with earth or ashes to the depth of 7 or 8 inches, and cut as soon as the first leaf peeps through. It may also be had fine in beds, covered with moveable wooden boxes the width of the beds, and with lids on one side if the boxes are too heavy to be easily moved. The worst of rough boxes is, that the sun will open the joints; this could be prevented by tacking slips of wood 1½ inch wide across each joint. A few open joints will interfere with the blanching of the Sea-kale. A very simple and good plan is to have raised beds 3½ feet wide, with two rows of strong plants in each bed, and 2-feet-wide sunk alleys or trenches between them, and to fill these alleys with sifted ashes. Mulch the plants in the beds in summer, to make them strong; remove all this surface-dressing, except the most decayed, in winter, and cover from 6 to 8 inches deep with the ashes. If the alleys are then filled with fresh dung, it will come in for top-dressing next summer, when the ashes are turned back again to serve for the blanching process in future years. For early supply, from the beginning of November, and onwards, the lifting and forcing in heat and darkness give least trouble.

Globe Artichokes.—These have stood the winter well, and we allude to them here chiefly for recommending a practice that

will be useful to those who like to have the use of this vegetable as long as possible—namely, to plant a row or a fresh piece every year, by taking not mere slips, but good pieces from large stools, by undermining with a pick and spade. These pieces will produce the same season, but the check of moving will cause them to produce a month or six weeks later than the general crop.

Asparagus.—Turned over the ground intended for a fresh piece, and in the absence of beds in which to grow and force, and, therefore, on the system of taking up a piece every year, we find it more convenient to grow it in rows, making these rows when planted in a rounded ridge-form, and depending a good deal on summer-mulching. We would scatter salt on our producing plantation now, as it would not only assist the young shoots, but would also assist in keeping the ground free from weeds. Any cleaning required should be given without delay, as the hoe is dangerous after the shoots begin to push up.

FRUIT GARDEN.

Much as in previous weeks, only we watered the pots and part of the ground in the orchard house with drainings from the farmyard. This liquid was not strong enough to need any dilution with water, and it was warm enough not to need the addition of hotter water. When water percolates through an open exposed dungyard, it is not often that much clear water will require to be added; but it is always safe to err on the side of weakness, and not to give such water too strong. We have seen liquid manure in a tank that had no ordinary rain or other water at all, and in that case we should have considered from eight to ten parts of clear water to one of the manure liquid essential to make it safe. Judgment must, therefore, be used, and treatment varied according to circumstances. Our latest house is coming into bloom in spite of us, and even Plums are now opening their blooms. We never saw the bloom stronger. Out of doors we are proceeding with pruning, nailing, &c., as fast as we can. Will surface-clean Strawberry quarters as soon as possible. Plants pricked out in beds last autumn may now be transplanted into well-aired ground, and will bear a good crop, as in most cases the fruiting plants can now be discerned—one advantage of this thick planting in autumn and final planting in spring, besides a great saving of ground at first. In stiff, good, loamy soils, little more will be required than planting with balls, and then slightly mulching the ground, but in all light soils the soil cannot be made too firm by treading and ramming after planting, and before the mulching is applied.

ORNAMENTAL DEPARTMENT.

Gave a good rolling, especially to the grass by the edges of walks. Had these cut straight with the line and edging iron; cleaned part of the walks, and will have to hoe others, where there is rather much green to permit of weeding and sweeping. Made banks ready in turf and earth pits, and turned the beds over roughly to become sweetened for bedding and other plants. Turf makes the best walls for such pits, but earth does very well firmly trodden, and covered with turf at back and front. These in some cases have stood many years; the turf on the top keeps frost and wet out of the walls. With glass these are as good for the purpose as brick pits or pits with wooden walls, and also answer admirably when coverings of mats or calico, or wooden shutters are used. Much has been done in finding room for young plants, regulating verandahs and conservatories, removing decaying plants, and supplying with fresh in bloom; sowing seeds, pricking-off seedlings, and making cuttings of all scarce plants or those which will be wanted in quantities. The general stock of Asters, Stocks, &c., we will deter sowing for a week or two, as we prefer they should not be stunted after they appear; and when the seedlings appear, and are then starved from the want of means to give them room and justice, they rarely succeed well afterwards. It is much better to sow later, and so that the plants may receive no check. Moved Dahlias to the floor of a house, where they could be advanced a little. Scarce good sorts should have been in heat earlier. Hardy annuals should be sown in light soils. In cold soils it is well to cover each patch with a pot until the young plants are fairly up. When regular beds are wanted this pot system is a good one; but when much regularity and perfection in outline are desired, we prefer sowing on a bed, with rotten dung and rough mould below the fine soil on the surface, and then hitting in lumps and transplanting. This requires more labour, but the result generally more than repays the extra trouble.

Goose or Furze.—This is now much valued for cover in many places. On a large scale it is best to sow it in the present or

in the first part of the next month, on ground made as fine as for a crop of Turnips, and then the seed will do best if sown in drills, and slightly covered and rolled. It likes a good loam best, though it will grow in most soils. In smaller pieces it may often be desirable to plant, and for this purpose, when grass, &c., was valuable for cover for birds, we have planted successfully by making holes 3 to 4 feet apart and putting two plants in a hole. We have also planted by making slits with a narrow spade so as to let the roots straight down. In all cases of planting, however, the stronger and the older the plants the worse suited are they for the purpose, and the less chance is there of their growing freely. The best plants are one-year seedlings, if they range from 1 to 3 or more inches in height. These in general will do well.

Frequently a small cover is wanted, and it is not desirable that the ground should be seen turned up, either by spade or plough, but that it should present its natural wild appearance, especially from a distance. In such a case, holes may be dug, or slits made for young plants; and for sowing, narrow strips 16 to 18 inches wide may be dug, with intervals 3 or more feet in breadth. In the centre of the dug part we draw a drill, and deeper than is wanted if we can readily obtain some light sandy soil riddled for covering the seed, and not so deep as to fill the drill. This plan has several advantages—first, there is no danger of stiff soil so incrusting the seeds as to keep them from the atmosphere and thus prevent their freely germinating; secondly, in light soils the seeds being deeper-placed, though not deeper-covered, the seedlings when young are less likely to be forced out of the ground, especially by frost, and if deemed necessary a little earth may easily be placed along the sides of the young seedlings; thirdly, the grass and weeds that will grow in the intervening spaces will in a withered state be a great protection to the Goats for the first year or two when it is often injured by frost and cutting winds. We have found the latter plan answer better than sowing in large breadth, covering the ground ultimately much better and more regularly, and the grass in the intervals was useful for nesting until the Goats covered the ground.

In all such cases of coarse plantations it should be clearly understood, that all the labour and the expense will be money thrown away wherever hares and rabbits abound, unless the young plants are protected from their ravages by wire netting or other means. Young plants are most eagerly cropped, and even rather old plants until well established are not safe. One would imagine that the prickles would be enough of protection, but there are some animals, like some men, that opposition and difficulty only whet into greater energy and determination.

Goats when cut young, and ground or bruised into a pulp, makes a rich pleasant food for cattle in winter. We have been assured that a horse will do as much work on a peck of bruised Furze as on a peck of the best Oats.—R. F.

TRADE CATALOGUES RECEIVED.

Downie, Laird, & Laing, Stanstead Park, Forest Hill, London, S.E., and 17, South Frederick Street, Edinburgh.—*Descriptive Catalogue of Florist's Flowers, &c.*

J. Salter, Versailles Nursery, William Street, Hammersmith, W.—*Descriptive Catalogue of Chrysanthemums, Dahlias, Pyrethrum, Hardy Vaccinated Plants, &c.*

J. Foulds, Hallard Hall Nursery, Stretford New Road, Manchester.—*Catalogue of Plants and Cuttings of New Zonal Bedding Pelargoniums, Fuchsias, Chrysanthemums, &c.*

Hogg & Wood, Coldstream, N.B.—Hogg & Robertson, 22, Mary Street, Dublin.—*Catalogue of Select Agricultural Seeds, &c.*

COVENT GARDEN MARKET.—MARCH 25.

THE market continues to be abundantly supplied. Good Pears are now very scarce.

TO CORRESPONDENTS.

.. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix upon the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

BOOKS (A. C. J.).—If you enclose 5s. 11. in postage stamps with your address and order "The Fern Manual," and 7s. in postage stamps and order Paul's "Rose Garden," you will have them sent to you free by post. (P. G.)—A supplement to the "Cottage Gardener's Dictionary" will be published this spring, and will afford the information sought.

FLOWER GARDEN PLAN (H. J.).—We cannot undertake the planting; all that we ever can do is to point out any errors in the planting intended.

BOTANICAL ARRANGEMENT OF PINES (Reader).—Consult Gordon's "Pinetum," or any botanical work which includes the Conifere. We cannot find space for mere botanical details.

GARDEN ENGINES (K. M. H.).—Nothing new. Any one of those mentioned in our advertisement columns is good, and you can suit yourself as to price. Any maker will send you a catalogue if you apply for one.

ARTIFICIAL MANURE FOR POTATOES (H. C.).—Apply superphosphate of lime and sulphate of magnesia, 4wt. of the former mixed with 2wt. of the latter. Sow the mixture over the surface, just before digging, at planting time.

LOQUAT TREES IN NEW ZEALAND (C. Torquay).—The old gardener was not so far wrong as he might have been. The botanical name is *Eriobotrya japonica*. The tree is well known, and it is not surprising that it ripens its fruit in New Zealand, for it has fruited in England with very slight protection.

POLYANTHUS (T. Mellon).—Such variations are very common, and render the variety of no value as a florist's flower.

NEPETA NIEPOTOS.—"L. C. F." and other correspondents ask if it grows tall, and where it can be had. We shall be obliged by information about it, for we do not know it by the name of nepetos.

DOUBLE WHITE HEPATICA.—"R. E. W." wishes to know where the double White Hepatica and Nepeta nepetos can be purchased.

HARTLEY'S ROLLED GLASS (C. E. S.).—The plants will do very well under a roof so glazed. Whoever advised you to oil or to paint it knew nothing about what he ventured to advise upon.

PELARGONIUM LEAF (Mrs. N.).—It is pretty, but many are more beautiful. You can enclose a leaf to any of the principal florists who advertise in our columns, and ask their opinion.

PINE APPLES IN A SMALL HOUSE (W. M. B.).—You will not have room in your 3-foot border for more than one row of fruiting plants, and for the length of house you name six plants will be sufficient. In the other bed you may have a row of succession plants and one row of suckers. Fruiting plants might be put in each bed; but if of any size you could not have succession plants in the same bed, and if the fruiterers are small only nursing plants could be placed between them in the bed.

MONTSERRAT AND BLACK JAMAICA PINE APPLES (Taffy).—The true Black Jamaica is the same as the variety also known as the Montserrat, and some still call it Montserrat to distinguish it from the Brown Antigua, or New Black Jamaica. The Black Jamaica is thus described:—"Leaves long, narrow, dark green, tinged with brown, slightly mealy; spines small, thick set; flowers purple; fruit oval, dark brownish yellow; pips middle size, flattened in the centre; flesh very firm, pale yellow, rich, juicy, and highly flavoured. It swells well in winter, and is one of the best sorts for winter fruiting, being good at all seasons; but it is a slow grower." The description of the Brown Antigua or New Black Jamaica is:—"Leaves long, narrow, light green mottled with dark green; spines small; fruit pyramidal, very slightly mealy, dark orange; pips middle-sized, prominent; flesh pale yellow, sweet, rich, and highly flavoured. It does not swell its fruit in winter nearly so well as the Black Jamaica, and is best for summer fruiting." Some call the Black Jamaica the Montserrat, and the Brown Antigua or New Black Jamaica the Black Jamaica, and others call the New Black Jamaica the Montserrat. The

variety with the flat pips is the Montserrat, or Black Jamaica, and the variety with prominent pips and pyramidal fruit is the New Black Jamaica. The "Cottage Gardener's Dictionary" can be had free by post from our office for 5s. 8d.

ARAUCARIA IMBRICATA (Idem).—This makes new growths every year; if recently removed it may remain inactive for a season, but as a rule a progressive annual growth is made.

PRUNING TEA-SCENTED ROSES (G. H. M.).—To have blooms at the end of June from plants grown under glass, these should at once be pruned. Allow them a few days' rest, and then bring them on very slowly at first, giving an abundance of air.

TREATMENT OF CYCLAMENS AFTER FLOWERING (Caroly L.).—The plants having been kept under glass should be gradually hardened-off, and in May or early in June they may be placed out of doors in an open situation, but shaded from the midday sun. The pots should be plunged to the rim, and a thin covering of cocoanut refuse or leaf mould scattered over them, so as just to cover the crown. They may remain until September without water; then pot them, and remove them to a cold frame, and to a greenhouse before severe frost. Do not dry them off and store them away. It is their destruction.

HOLLY NOT PRODUCING BERRIES (L. B.).—We are unable to account for your large Holly not producing berries. We think digging a trench all round the tree at a distance from the stem of half its height, and deep enough to reach the roots, which should all be cut, would promote the production of fibres and give you better ripened wood, and the flowers would probably set. The trench should be filled level, the old soil being returned. Now is a good time to do the work. The grafting of a shoot from a berry-bearing tree would not cause the tree to produce berries, but the graft would no doubt do so. You may graft when the large tree is beginning to grow, early in April being a good time.

THINNING FRUIT BLOSSOMS (E. A. S.).—As your trees are very full of blossoms we would advise you to thin those out before they expand. Remove the smallest flowers, or rather those likely to be the smallest, judging from the small size of the buds. There is no fear of your removing those that would set, and if you do leave some that may not set, you will yet have more than enough. It is likely if you leave all the blossoms that they will not set, or, if they do, the tree will be so weakened that the fruit will fall shortly after setting. Thinning the blossoms is a very desirable practice when the trees are weak, and the blossoms exceedingly numerous; otherwise for trees that are vigorous and not excessively furnished with bloom, it is not necessary.

CULTURE OF MAIDEN-HAIR FERN (E. M. H.).—Your Maiden-hair Ferns should have a season of rest at least once a year, and of not less than three months' duration. We do not mean that the plants are to be kept dry during that time, but in November, December, and January they should have no more water than is necessary to keep the soil moist. During that period a temperature of from 50 to 55 at night is quite sufficient. We are not surprised at their growing weakly, a heat of from 60 to 65 during winter is much too warm for nine-tenths of the Ferns in cultivation; from 50 to 55 will be quite sufficient to secure a good growth in spring and summer. We would advise the cutting-off of the old fronds as soon as you perceive the young fronds are making their appearance, and this being done early there is no danger of cutting the young fronds along with the old ones. When at rest the soil should be kept moist, but water will not be required other than once a week in winter. We do not advise cutting away the old fronds immediately they commence turning yellow, but between that time and the recommencement of growth. Alford a position near the glass, with shade from bright sun, and a moist, moderately warm, but not very close atmosphere.

WATERING ORCHIDS, GLOXINIAS, AND ACHIMENES (Subscriber).—Orchids should be watered overhead, and at the roots as well if the compost is not kept sufficiently moist by sprinkling overhead. In a greenhouse no water will be needed in winter beyond a slight sprinkling every morning if it be necessary to employ fire heat. When Orchids begin to grow water will be necessary, for keeping the compost moist, but avoid making it excessively so during the early stages of the plants' annual growth, otherwise the young growth is liable to die off. When in full growth water copiously, and the atmosphere cannot be kept too moist; but give a fair amount of air. When they are done growing, gradually leave off watering. In dull periods in winter no watering at the roots nor sprinkling overhead will be necessary; indeed, you cannot keep them too dry, but do not allow the pseudo-bulbs to shrivel from excessive dryness. Gloxinias and Achimenes should be kept dry in winter; and if the pots are placed on the floor of the house, only an occasional sprinkling over the pots will be required to prevent the soil becoming dust-dry, in which case the tubers wither, which is bad. In summer, when growing, the soil should be kept moist, increasing the supply with the growth. When in vigorous growth, and until after flowering, they should be well supplied with water, the soil never becoming so dry as to affect the foliage.

PEACH TREES INJURED (Disgusted).—We consider that the wood of your Peach trees has been destroyed by dressing or syringing with some destructive composition. If the trees have not been dressed with any insect-destroying composition or solution, we should, from the immaturity of the wood, ascribe the dying of portions of the shoots to gumming, for which there is no remedy except planting in better-drained and poorer compact. We never saw wood worse ripened. The partly green or fresh portion above the decayed wood will not do any good. If the trees are as much decayed in every part as the shoot sent, they will not do any good this year, if ever.

DALE'S CONQUEROR CUCUMBER (H. E.).—It is a first-rate Cucumber, of large size, very handsome, and of good flavour; very desirable for exhibition purposes, and for use where a Cucumber is not wanted every day. It does well in a frame, and may be had through any seed-man.

PASSIFLORA RACEMOSA PURPUREA (Walton-on-Thames).—It is a greenhouse climber, and will not thrive out of doors except in a warm situation and against a south wall, protection being given in winter. The flowers are a bluish purple tinged with green.

CLIMBERS FOR NORTH ASPECT (Idem).—Nothing would look and succeed so well as Ivy; Ruger's Ivy having large distinct leaves is very fine. Crataegus pyracantha, which is very handsome on account of its clusters or bunches of red berries in autumn, would also succeed. Roses would not do any good, Jasminum nudiflorum, flowering in winter

and early spring, would succeed well. It has yellow flowers, but it is deciduous.

DOUBLE DAISIES CULTURE (G. S.).—Double Daisies do best in a border shaded from the midday sun. They should have a rich, moist, and rather stiff soil. They should be divided after flowering, and watered copiously in dry weather. The soil should be well drained, for they are impatient of wet in winter, and equally so of drought in summer.

HERBACEOUS PLANTS (H. N. C.).—*Viola cornuta*, *V. pennsylvanica*, *V. calcarata*, and all the varieties of *V. odorata*; *Trollius europæus*, *T. napellifolius*, *Spirea filipendula plena*, *Scilla sibirica*, *S. bifolia*, *Pulsatilla angustifolia rubra*, *P. officinalis*, *Draba aizoides*, *Dicentra spectabilis*, *Doronicum plantaginifolium*, *Erigeron grandiflorus*, *Galium boreale*, *Delphinium formosum*, *D. Belladonna*, *D. grandiflorum*, *D. alopecuroides*, *Chelidonium Marshallii*, *Convallaria majalis*, *C. polygonatum*, *Campanula aggregata*, *C. carpatia*, *C. speciosa*, *C. pusilla*, *C. nitida plena*, *Asclepias tuberosa*, *Anthriscus grandiflora*, *Aster alpinus*, *A. tataricifolius*, *A. tenuifolius*, *Betonica grandiflora*, *Aquilegia caryophyllifolia*, *A. grandiflora*, *Aconitum paniculatum*, *Anemone stellata fulgens*, *A. japonica* and varieties *vitifolia* and *Honorine Jobert*, *A. apennina*, *Alyssum saxatile*, *Ajuga alpina*, *Agrostemma coronaria*, *Achillea millefolium rubrum*, *Geranium sanguineum* and *lanceolatum*, *Geum coccineum* its variety *grandiflorum*, *Helleborus niger* and variety *major*, *Hepatica triloba* and *angulosa*, *Hypericum calycinum*, *Iberis saxatilis*, *I. Tenoreana*, *Iris germanica* vars., *I. pallida*, *I. reticulata*, *Lilium aurantiacum*, *L. candidum*, *L. colchicum*, *L. chalcedonicum*, *L. Martagon*, *L. tenuifolium*, *Lotus corniculatus flore-pleno*, *Lycinis viscaria splendens*, *L. Haageana*, *Mimulus roseus pallidus*, *Orobis vernus*, *Pæonia albiflora* vars., *P. officinalis* vars., *Phlox verna*, *Polemonium ceruleum*, *Potentilla Menziesii*, *McNabiana*, and *bicolor grandiflora*. All the above will grow in your cold climate.

ASPARAGUS PLANTING (Idem).—The beginning of May is the best time to plant Asparagus, but it may be planted now.

STRAWBERRIES UNPRODUCTIVE (P. L.).—Your light loamy soil ought to be very suitable for Carrots. Trench the dung you use to the bottom, say to 16 or 20 inches from the surface, and after sowing roll firm. The ground being so light, give, as you have done, plenty of manure to your Strawberry plot; but after preparing the ground tread it firm and roll on the surface before planting. Tread well after planting, then mulch between the rows with rotten dung, and never dig until you dig down the plants, but merely fork an inch deep or so every season, add fresh mulching, tread if not firm enough, and we will almost guarantee that you will gather plenty of Strawberries, if you plant from fruitful plants.

PLANTING MUSCAT HAMPER VINE (H. W.).—We would prefer planting the Muscat Hamburgh, or Black Muscat of Alexandria, in your late and cooler house.

HEATING A GREENHOUSE.—CUTTING DOWN RHODODENDRON STOOLS (E. M.).—We consider that the proposed quantity of piping will be ample for the house. We would certainly lose no time in cutting down the central part of your Rhododendrons, as the outsiders near the ground are doing so well. Most likely the central parts will break strongly. If the branches are large we would cut them neatly, and then daub the cut part with white lead paint, darkened so as not to attract attention. This would prevent damp, &c., acting on the cut part.

FLOWER GARDEN PLANTING.—We must decline to plant beds; we merely criticise proposed planting. As you prefer bedding Pelargoniums you could, as you propose, fill the centre with Mrs. Pollock, and the other four beds—two with Christine and two with Alma. We would prefer for the large central bed a string of *Cerastium* next the grass, then a broad band of *Lobelia erinus speciosa*, and in the centre all through Mrs. Pollock; for the two side beds Christine Pelargonium, edged with Purple King Verbena, and two beds of Little David edged with variegated Alma or Bijon; the former preferably. (J. L.).—With a row of *Centaurea* outside, and then a row of *Colerus*, we would prefer *Cerise Unique* or *Stella Pelargonium* for the centre of the bed to Bijon, as that would make too much of a light colour. One of the most striking beds we ever saw was formed of the dark *Colerus*, with a broad margin of white-leaved *Cineraria*, or *Centaurea*, we forget which, at Woburn. It was as a single bed very fine, the *Colerus* being healthy, and its richly coloured leaves of a fine satiny texture.

ERECTING A SMALL CONSERVATORY (M. E. G.).—Ribbed glass or rough sheet will let in plenty of light for the roof of your conservatory, and you will require no shading. With common British plate we have seen the same result accomplished by painting the glass inside with a bluish tint, which looked very well, answered for the plants well, and needed no shading. The front glass you had better have clear with thin blinds. As to the flooring, as a matter of taste, ornamental richly coloured tiles will always look better than flagstones; but the latter will stand the roughest treatment.

CLIMBERS FOR A SMALL CONSERVATORY (Idem).—*Ipomœa Leatii* will do in a cool conservatory that is heated so as seldom to be below 45° or even 40°. Lower than that it will die. We presume your house is to be heated, and then you will grow *Lapageria rosea* well if you give it plenty of drainage, a rather shallow soil, and plenty of water. All the *Tasconias*, *Kennedys*, and hardier *Passifloras* would do well in such a house. When once they are established they will give plenty of shade in summer. *Habenorrhynchus clemeas* is a fine plant for blooming all the winter, and *Mandevilla suaveolens* yields a profusion of white flowers in summer.

GROWING CUCUMBERS WITHOUT ARTIFICIAL HEAT (Tyro).—You may grow Cucumbers in the yard with the help of the frame without artificial heat, by elevating the frame sufficiently behind to catch the rays of the sun as much as possible. Bring the earth in by the beginning of May, turn it over frequently so as to get the soil warm, and keep the warmth in after a warm day by throwing a mat or rug over the glass. By the end of May or the beginning of June turn out your plants. You had better have strong plants from some neighbour; failing that, sow near the chimney in the end of April, and place afterwards under a bell-glass or thin paper funnel in the window of a warm room. If you obtain a few plants well hardened-off, they will suit you best. You may have a great deal of heat if you take advantage of what the sun affords you. We are supposing you want to grow good kinds. For short common kinds you would have little necessity for being so particular. Tomatoes may be grown very successfully in pots and boxes, and so they might against the walls or fences in such a yard.

CAUSE OF DEW ON VINES IN THE MORNING (E. W.).—If you mean the moisture condensed on the leaves of Vines under glass, the cause is that the leaves are colder than the air of the house, and the moisture in its air is consequently deposited upon them. Read Johnson's "Science and Practice of Gardening." It explains the formation of dew, and the reason of most phenomena in horticulture.

WEEDS ON LAWN (H. D.).—Send us specimens in flower, and we will tell you what they are. We cannot guess, for they vary with the soil. Daisies are best eradicated by cutting them out of the turf by means of a knife, taking care to cut through the roots an inch or more below the surface. The grass soon covers over the vacant spots; or to hasten the process of covering, sprinkle half a dozen seeds of Suckling on each vacancy.

PEA SUPPORTS (An Anxious Inquirer).—The best answer we can offer is the following extract from one of our early volumes:—"We have had them in use now without repair for three years, and can strongly recommend them. The only alteration we find desirable is that, instead of

having the supporters fixed upright, as in these sketches, they should lean inwards, and their tops touch in this manner A. We paid 6d. for each hurdle of unplanned deal, and had it painted over with coal tar. For the purpose of obtaining a more durable, and, therefore, less expensive supporter for Peas, we have had a kind of hurdle made with only a top and bottom bar, and these bars pierced with holes 6 inches apart, as represented in the annexed drawing, fig. 1. To prevent confusion in this we have only shown one of the hurdles as pierced with holes, and with string passed through them; but, in practice, both are strung alike. Each hurdle is 5 feet long, and 3 feet wide between the two bars; for tall-growing Peas the width might be more. The upright ends are made of deal, and are 4 feet long and 2 inches square. Eight inches of the lower ends are charred and pointed, because they have to be fixed in the ground. The side bars are 2 inches wide and 1 inch thick, also of deal, sunk into the uprights, and then nailed. The Peas are sown in double rows, with a space of 9 inches between the rows. The hurdles are strung with stout wetted string, because when dry it becomes tighter, and rain does not slacken it afterwards. A hurdle is put outside of each row of Peas, and is made steadier by being tied to the one next to it, and the whole made firmer by being united to those opposite by pieces of wood about 1 foot long, tied as shown in fig. 2.

HEXAGONAL VINETTES (H. G. M.).—Write to Dr. Newington, The Vinery, Ticehurst, Sussex.

SEEDLING BROCCOLI (G. Cooling).—The heads are very white, compact, and firm, and remarkably pyramidal in form, and it is the more useful as being a second-early variety, not coming in all at once, but, as you say, allowing of being cut from the same bed for three successive weeks.

ARBUTUS PROPAGATION (E. G.).—You may put in cuttings of the shoots, selecting moderately strong shoots of the current year, their points being taken when in the condition of half ripe, or when the base has become firm. The cuttings may be about 4 inches long, and should be inserted in a capot of equal parts sandy peat and silver sand, previously cutting them transversely below a joint, and removing the leaves from two-thirds the length of the cuttings, which part is to be inserted in the soil. They should be placed in a mild hotbed, keeping moist, close, and shaded from bright sun; or the cuttings may be inserted in a cold frame, which should be kept close until a callosity is formed. It is rather difficult to increase the *Arbutus* from cuttings. Layering is a more certain mode of propagation. Seeds of the kinds you name are not to be had.

APPLE TREE SHOOTS DISEASED (C. C. E.).—The shoot enclosed to us appears to have been attacked by mildew. The best remedy would be to take up the tree, well trench the ground, and replant. Flowers of sulphur should be applied to the shoots when the symptoms first appear and be continued as necessary.

FIXING WIRE TRELLISES TO WALLS (Idem).—We have several hundred superficial yards of wall covered with wire for fruit-tree training, and have no difficulty in fixing them. We simply have a plate of iron 14 by half an inch, the height of the wall, and with an eye screwed into the plate at every 4 inches, the first eye being put in the plate 9 inches from the ground. These plates are made secure to the wall by means of hold-fasts at each end, and the wire being made straight by straining, is fastened to the eyes in the iron plates at the end least convenient for straining. Previously to doing this a number of hooks about 3 inches long, flat half an inch by quarter of an inch, with a hole in the flat side of the hook to allow of the wire being passed through, are driven into the joints of the brickwork at a distance of from 3 to 4 feet apart,

and so as to maintain the wires three-quarters of an inch from the wall. The wire is then strained and made secure to the hooks in the plate of iron at the other end, and it has a neat appearance. No. 10 galvanised wire is used, and the hooks are galvanised also, so that no point is required except for the iron plates at each end. We have used many yards of diamond netting for placing against walls, the netting having a sort of rod-framing around it, which it was only necessary to secure to the wall with holdfasts, with the shoulder made the reverse way, and driven in; the netting could be placed any distance from the wall by driving in the holdfast little or much, and having placed it as near the wall as desirable, the flat portion of the holdfast or hook could be bent over the rod or frame of the wire, and so made secure. For fruit walls we prefer horizontal wires, but for plants the wires crossing each other obliquely. The work is in the latter case neater, but more than double that of horizontal wires.

CACCI INFESTED WITH SCALE (J. A.).—Your plan of picking the insect off is a slow but sure means of clearing the plants. You may, after picking off all you can, wash the plants with a sponge, using a solution of 1 ozs. soft soap to the gallon of water. If you cannot sponge them on account of the spines, immerse the plants for a minute in the solution at a temperature of 120°. If you cannot immerse them, syringe them with the solution at a temperature of 140°, and when the plants become dry syringe them with water of the same temperature as the soap solution.

SCALE INSECT (Ignorance).—There are several sorts of scale; but the most likely one for you to have is the brown scale, which, however, rarely attacks *Pelargoniums*. It is like a small oblong speck, and lies quite close to the shoots or leaves, covering them with a sticky substance, which ultimately becomes black. The best remedy is to pick it off with a knife whilst young, and to keep the plants clean by frequently sponging the leaves and stems with a solution of 4 ozs. of soft soap in a gallon of water. See the preceding answer. Do not use the soap solution for the *Pelargoniums*, for the scale we are sure will not long remain upon them, and we think it is communicated to them by plants more subject to attack. Placing the plants out of doors from June to the end of September or early in October, will free them of scale.

VENTILATING A SMALL GREENHOUSE (Idem).—The sash opening in front and the door opening will be sufficient ventilation; but we should have liked it better if you had had one or two openings at the highest point of the roof, as your house could then have had ventilation in dull and frosty weather when you could not well have the door and sash open.

STANDARD MIGNONETTE (A. H. F.).—The seed should be sown now, a few seeds in the centre of a small pot, and be placed in a mild hotbed; and when the plants are up keep them near the glass, and so soon as you are able to decide upon which are likely to be the best, remove all from the pot except one—the strongest of course. When the plants are 2 or 3 inches high remove them to a cool house, placing them near the glass, and afford an abundance of air with a moderate amount of water; but see that they do not suffer for want of it. When the pots become filled with roots the plants should be shifted into others a size larger, and this repeatedly until you have them in 9-inch pots if you require them so large; if not, a 7 or 8-inch pot will do. A neat stake should be placed to each plant, and the plant as it grows loosely tied to it. The flowers should be pinched-off as they appear, and the side shoots stopped

within one or two joints of the stem, and at every leaf afterwards, always taking care to secure the best of the shoots for a leader, training it to the stake; when it again shows flower pinch it off; the best of the side shoots, and the uppermost of course, being trained in its place without being stopped until it shows for bloom. Proceed as before until you obtain the height of stem required; then allow the side shoots for 2 or 3 inches down the stem to grow, stopping them, however, at the third leaf, all the side shoots below this being kept closely pinched back to one joint, and when the shoots of the head have made new growth after the first stopping, the shoots lower down may by degrees be removed; but we prefer to retain them, as the stem is prettier feathered than bare. The shoots of the head will need to have the flowers pinched-off, and this should be practised until September, when the plants should be placed under glass.

GLADIOLUS BULBS (Gladiolus).—You may dip the bulbs in a mixture of soot and sulphur without injury, and it will make them very distasteful to predatory vermin.

SUPPORTING BLOOMS OF CUT ROSES WITH WIRE (Idem).—It would be a disqualification to a stand of cut roses to support the petals by a ring of wire concealed by the foliage. It being habitually done by exhibitors is no reason for others imitating so dishonest a practice.

CORRUGATED GLASS FOR GREENHOUSE (J. H.).—We have had some experience with the rough glass you name, but we cannot say that we like it; indeed, we find no glass equal to 26-oz. sheet, third quality; and as to shade, we consider glass so full of impurities as to cause gloom very injurious to vegetation. It is best to use clear glass, and shade with tiffany in summer. The plants cannot have too much light from September to April.

CLIMBERS AND TRAILERS FOR ROOTERY (New Subscriber).—The best of all will be the small-growing green and variegated *Lyca*, Virginian Creeper, *Cotoneaster microphylla*, *Convolvulus sepium roseus*, *Vincetoxicum*, for trailing, *Clomitis viticella*, *C. Helena*, *C. montana major*, *C. vitalba*, *C. viticella venosa*, and *C. florida plena*, *Caprifolium odoratissimum*, and *C. periclymenum*.

HOT-WATER PIPES FOR BOTTOM HEAT (J. H. F.).—Two 3-inch hot-water pipes will be sufficient for bottom heat for your Cucumbers; but instead of 3 inches of stones we would cover the pipes with slates and form a sort of chamber, then place on the slates 3 inches of stones for drainage, and then the soil; 1 foot deep will be ample.

CRICKETS (M. A. H.).—Please to refer to page 202 of our last number on.

DWARF TROTTLE (Notttingham).—There are many dwarf varieties. Any of them can be obtained of the principal florists who advertise in our columns.

NAMES OF PLANTS (H. H. H.).—1, *Cheilanthes fragrans*; 2, *Pteris serrulata*, (*H. B. Z.*)—1, *Adiantum formosum*; 2, *A. carolinianum*; 3, *A. capillus-Veneris*; 4, *Pteris serrulata*; 5, *Polystichum angulare*, var.; 6, *Selaginella Kraussiana*; 7, *S. Martensii*; 8, *Pteris cretica albolineata*; 9, *Onychium japonicum*. (*H. M.*)—1, *Asplenium bulbiferum*; 2, *Cheilanthes lundbergii*; 3, *Blechnum occidentale*; 4, *Notochorda nava*. (*H. E.*)—You have sent indeterminate scraps. (*Ellis*).—*Daphne mezereum*, (*H. B. E.*)—*Echeveria acutifolia*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending March 24th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

LIGHT AND DARK BRAHMAS.

SOME remarks upon a former communication of mine on this subject by my friend Mr. Crook (for I trust that our little differences of opinion will never alter the friendly relations which have always existed between us), make a word or two in reply imperative, as they imply that my comments on the Birmingham birds were founded on mistakes in recollection.

Mr. Crook will, however, look in vain for any observation of mine that the cup cock belonged to Mr. Pares. I never mentioned or implied his owner's name, simply speaking of him as "the first-prize Light Brahma cock;" any mistake in memory is therefore his, not mine. And as to "anomalies," what shall we say to Mr. Crook's "noting" the bird as of "good colour, both surface and ground," and subsequently remarking that "we all agreed that his surface colour was the worst in the class?" I certainly understood him to object to the bird on account of colour solely—if I misunderstood him I beg his pardon—and I see that his notes describe him as "not a good shape." Well, here certainly is a difference of opinion as to

the proper shape of a Light Brahma. I commended his shape, judging him simply as a Brahma by the Brahma standard; and therein I apparently coincide with Mr. Teelay, in my opinion the best judge of Brahmas of any man living. Mr. Crook says he is "not a good shape," having reference to the modern standard of Light Brahmas as now shown. May I venture to suggest that this standard may be a false one, and may possibly account for the present position of the Light classes? If there be such a thing, and there is—for Miss Watts is quite correct in maintaining that the Brahma is but one breed, as Cochins are—as a true Brahma type or standard common to both colours, and the Dark fanciers on their part do their best to keep to it and perfect it, whilst the Light are following after some totally different idea, it is not difficult to predict what the result must be when a real Brahma judge has to decide between them.

With regard to the comparative merits of the Birmingham cockerels, I made no remark upon them whatever; and as it does not touch on the subject, shall not in any way criticise Mr. Crook's remarks.

But returning again to the point at issue, how singularly does Mr. Crook's challenge corroborate the opinions I have expressed. He will show twelve Light hens against twelve

Dark—but on what conditions? “Age, perfection of colour, and markings” to be chief points—the very thing which “Y. B. A. Z.” and myself contend has led to the present state of matters. Not a word of even size, and, much less, not a word of shape or Brahma symmetry. Now this latter point—symmetry, or perfection of form and characteristic points, is the very A, B, C, or foundation of all excellence; but it is to be swamped by colour, as, alas! it too truly is!

So that with regard to Mr. Crook's opening paragraph, I do emphatically repeat my opinion that, judged by the only real standard, Light Brahmas are a “degenerate race;” that (as a class of course I mean—single good birds I do see), they are far inferior to the Dark in purity of race, comb, head, shortness of leg, depth of keel, and squareness of build. But do not let me be further unfairly charged with maintaining that they are “difficult to breed true to characteristics.” This I deny. It is as easy to breed one Brahma as the other, only a true and characteristic standard must be sought after in order to attain success. This many of the Dark breeders have kept in view, this nearly all the Light breeders have in a great measure discarded. And as to describing us who assert the inferiority thus produced as persons who have “not properly understood the breed, and as a matter of course have not been successful with it,” Mr. Crook must surely forget that the very origin of the whole discussion is the fact that he and other admirers of the Light breed have “not been successful with it” themselves! We think—we know that we can point out the reason; he, despite of the well-known general principle, can or will see none.

Mr. Crook's remarks on three different original strains and their characteristics, open a further field for profitable remark, and one in which I have taken great interest, but can only make one or two observations which bear upon the matter in hand. We have first “Mr. Burnham or Dr. Bennett” (though Bennett's, by the way, was quite distinct, characterised by the “creamy tinge,” but having “the defect of being too white down to the skin.” Here at once is evidence “presumptive” of a Cochin cross; and what do we find? Why, as all know, Burnham with unblushing effrontery acknowledges that his birds were produced all from Shanghae hens. Similarly his Dark Brahmas were produced from grey Cautagong coeks crossed with Cochins. In spite of the immense mass of evidence tending to show that Brahmas are a distinct race, that some of the so-called “original strains” were thus produced there can be no doubt; and hence much of the perplexity which awaits all who candidly investigate this most interesting subject. Hence also the Brahmas without the “gronse head,” which Mr. Crook most truly says are still bred in America, though the gronse-headed Brahma is also well known there. In fact, between the original pure-bred Brahmas, the “original” made strains such as Burnham's (which latter, Dark especially, caused infinite disappointment, rarely breeding two birds alike), the more modern crosses with Dorkings and Cochins to gain points of colour, and their various intermixtures to subdivisions, any who conscientiously investigate the origin and history of Brahmas will find that they can discover “very little to swear by, but a great deal to swear at,” and also a great deal of reason for much difference of opinion.

Let me take the opportunity of assuring Mr. Pares that I never meant to deny the existence of many excellent birds with the proper grey bottom colour; nor would, I think, my letter be so read. I simply meant, and I repeat, that I have parted the plumage of very many Light Brahmas with the result stated.—Nemo.

Here the controversy may end. We see no valid reason why Light and Dark Brahma Pootras are not entitled to cups and other separate prizes, just as much as Buff, Partridge-coloured, and other varieties of Cochin-Chinas.—Eds.]

BRAHMA POOTRAS—DORKINGS AND THEIR CROSS-BREDS.

I AM in possession of a Dark Brahma pullet, one of a pair hatched from eggs laid by the same hen on the 10th of May, 1867. They both began to lay in the second week in November. One of them I was obliged to kill on the 10th of February, as her egg organs became badly inflamed. She laid an egg nearly every day from the 19th of November to the day before I killed her. The other has continued laying up to the present time without becoming broody, or ever missing more than one day at a time, and that very seldom. During January she

missed six days, in February none, in March two to the present time. I kept no account of the days when she did not lay in November and December; but allowing her to have missed seven in December and four in November, she will still have laid 115 eggs to the 23rd of March, which is, I consider, marvellous work, as she will not be twelve months old until the 10th of May. Her eggs are large for a Brahma, the usual weight being 2½ ozs.

I find a great difference in the laying and tendency to incubate of my Brahmas, although all are equally pure bred. One of the pullets from the same brood as the other two began to lay about a fortnight before them, and has been broody twice; the latter time I sat her on some eggs, and her chicks are now nearly a week old.

The other breed I keep are dark-coloured Dorkings. I find that the pullets begin, as a rule, to lay rather earlier than the Brahmas, though they oftener miss a day, and are more influenced by changes of the weather, severe cold causing them to cease laying almost entirely, while the Brahmas do not appear to be in the least affected by it.

I may mention as a comparison of the early-laying powers of these breeds, that on the 10th of March last I had a mixed brood hatched; among them were three Dorking pullets, which, singularly, each laid their first egg on the very day they were five months old—viz., on the 10th of August. The Brahma pullet did not lay until from a fortnight to three weeks later.—R. W. BEACHEY, *Kingskerswell, Devon.*

BARNDORF FOWLS.

At a recent meeting of the Boroughbridge Agricultural Association, Mr. Gaunt read a paper on barndoor fowls.

He said that twenty years ago the very proposal to read a paper at an Agricultural Society like this, on the subject of breeding and managing barndoor fowls, would have been looked upon by the kindly-disposed of its members with curiosity, as something very singular, and by others with a feeling very much akin to scorn. In those days nothing would have been—nay, even in these days, nothing is deemed—more derogatory to the British farmer than to suppose him capable of taking any interest in those beautiful and useful inhabitants of the feldyard, further than to help his goodly spouse to a decision as to whether the couple of capons for dinner should be roast or boiled, or to express his anxiety as to the number of minutes his eggs should be cooked for breakfast. This should not be so; for the very fact that enormous numbers of eggs and poultry are annually imported both from France and Ireland into this country, must show that the production of them is a source of profit, or the supply would naturally cease. The question at once arises, Why should we be dependant upon our neighbours for sending us the very commodities which we have the power not only to produce, but to produce in the highest perfection? for it has been truly said that the English farmyard is the paradise of poultry. One reason is, that the rearing of poultry in large numbers has never been thought worthy the consideration of the farmer himself, though there is no doubt that it may be made a source of great profit, with a very slight outlay of capital; and another cause is the utter disregard that has been paid to the judicious breeding and crossing of the various kinds of fowls. They are allowed from year to year to run on in the same folds without any admixture of fresh blood, and in consequence become puny, small, and weakly, so that half the number hatched are unable to struggle to maturity, from their excessive liability to the numerous diseases which poultry “flesh is heir to.”

During the past few years the magnificent poultry shows which have been held in most of our principal towns and villages, have drawn much attention and given an impetus to the breeding of poultry, and great has been the admiration excited by the pure-bred specimens of the numerous varieties. What, indeed, can be more beautiful than the thorough-bred Game cock, with his flashing colour, his serpent-like head, and his lordly carriage, showing not only that he is, but that he knows himself to be, the true aristocrat of his race? Other classes are not behind him in beauty of a different kind; truly they have not his magnificent plumage or defiant eye, but the comfortable shapeliness of the Dorking and the Brahma Pootra hens, suggestive of their motherly propensities and of their satisfactory appearance on the table, speaks volumes in their favour. But these thorough-bred birds, valuable as they are, and profitable also, are not what a farmer should have as barn-

door fowls. They require far too much care and attention to repay him, and eggs at one shilling each (as many are charged from prize birds), are quite too dear to be trusted to the care of farmers' lads. The name "barndoor fowl" suggests in itself the mode in which a farmer expects his poultry to pick up a living—literally by eating the grain dropped from thrashing and various other farming operations, and the seeds and insects procured by scratching in the dunghill, which, besides feeding, causes them to become public benefactors; for the very seeds they eat would, if returned to the land, propagate a rank crop of weeds.

The question now arises, What cross or crosses of pure-bred fowls will produce at once the largest, best-flavoured, and healthiest chickens? The one I strongly recommend is that between the Game cock (chosen rather for its size and abundant plumage than for its warlike proclivities), and the Grey Dorking hen. It is generally admitted that the Game bird is the best for the table; it is also a good sitter, and an excellent mother; but it lacks size. This quality the Dorking gives, and the progeny of the two grow to great weight, frequently quite as large as the pure-bred Dorking itself. They lay and sit well, and the mixture of the Game blood gives a better flavour to the chickens. A further cross in the following year will be advantageously made with the Brahma Pootra fowl, and the third year it will be found wise to turn a few young Game cocks or Malays into the foldyard, so that by continually introducing fresh blood is avoided that most pernicious system of breeding in-and-in, to which I have previously alluded. There are many crosses from which good fowls may be obtained; but I do not think any equal to that I have described—viz., between the Game, the Grey Dorking, the Brahma Pootra, and the Malay.

Although for the sake of obtaining eggs at a season when they are most expensive, it is a wise plan to save each year several pullets for laying, still the eggs to be placed under the sitting hen should be those laid by two-year-old birds, as they will be found not only more certain to contain a chicken, but the chicken will be stronger than any produced from the egg of a pullet. The number of eggs to be set under a hen varies according to the size of the bird and the season of the year. My impression is that too many are generally set, and that the consequence becomes manifest in the weakness of the chickens. In no case should there be more than thirteen eggs, however large the bird, and in most cases ten or eleven are quite sufficient; indeed, in very cold weather, nine eggs are enough for the largest bird to cover. The good effect of setting comparatively few eggs is observed in the strength exhibited by the chickens in escaping from the shell, and the fact that they are all hatched at the same time.

Having shown what description of cross-bred fowl is the best for the farmyard, the next point will be to consider in what manner such birds may be kept in the best health. The only time at which a fowl having the general run of the farmyard really requires any extra assistance is during the time of moulting. That operation is to the fowl a great effort of nature, which doubtless, when in reasonable health, it can manage to get through without artificial assistance; but if, by giving a little advantage in the shape of food, at but slight expense, the bird can get through its difficulties in half the time it would otherwise do, I think every one will admit that a little attention to this point will give a good return for the trouble. At this season, therefore, I strongly recommend that all fatty substances left after the farmhouse dinner, such as the crust of meat pies, pieces of pudding saturated with gravy, and all scraps of meat, shall be carefully collected, cut up, and well-mixed together with black pepper, and given to the fowls. The effect of this treatment is most astonishing. It just gives to their nature the required impetus, and enables each bird to complete its moulting, as before stated, in about half the time it would otherwise have taken, and it is ready once more, with renewed vigour, to repay its possessor cent. per cent, upon his slight outlay of trouble, I will not say expense, for the amount really expended will have been so trifling that it can scarcely be calculated.

Between the months of November and March the farmer has great opportunities of doing well to his fowls, and again at very little cost; for there are generally operations going on in his house which enable him to give them a considerable quantity of extra food. I allude to the killing of the fat pigs, which takes place periodically at this season, and every bit of refuse meat should be carefully saved, boiled, and cut up. The broth or liquor consequent upon the boiling should be mixed with common meal, and the whole made into one compound, and

given to the fowls once a-day. Black, or even in very cold weather, a small quantity of cayenne pepper may be added to this with good effect.

I am not by any means an advocate for coddling fowls in warm hen houses, because I believe the injury done to them by a sudden change of temperature is much greater than any advantages which may accrue from their being in a heated atmosphere during the night. The hen that comes from a cold night's lodging feels no great difficulty in getting up (or rather down), and going out early in the morning to "pick up the early worm;" but the hen from the warm and enervating roost fears to brave the inclemency of the weather, picks up what little corn may be thrown to her near the door of her hot-house, and retires with dainty steps as soon as possible, preferring rather to dose out her existence on her comfortable perch than to live a life of activity and search after food. At the same time, a slight, but very slight, artificial heat is of advantage during the winter months, though not by any means imperative. Therefore, if with perfect convenience one wall of the hen house can be attached to any building in which a daily fire is kept—for instance, a harness room, a boiling house, or a blacksmith's shop—and a flue can, with little expense, be run up between the two buildings, the fowls will derive good from it.

It is very important to arrange the breeding of fowls in such a manner as to have both eggs and chickens ready for market at the time when they are most in request and command the highest prices. There is no art in getting fowls to lay well, and to sit and bring up their chickens in the spring months; but the great point is to have eggs during the moulting season, and thence to the end of January, and also to have what are termed spring chickens ready for market in the first three months in the year. To obtain these, hens should be put to sit late in October in some cow house or outbuilding opening into a small foldyard, so that the chickens, when hatched, can be turned out for two or three hours in the middle of the day; and after the first month they will require very little care, and will be sold at a remunerative price. In order to ensure a supply of eggs when they are most valuable, the hens should sit at the end of January or beginning of February. The cockerels from these hatchings should be sold in May, when there is no Game, and the pullets will begin to lay early in autumn, and will continue to do so during the winter months.

Mr. Bainbridge said that last summer a friend of his had obtained some hens from the Cape of Good Hope, and they were placed amongst some Dorkings. These hens, after a time, began to hang their heads, and appeared likely to die. Some garlic and hot bran were given to them, and a little pepper was added as a stimulant, and the result was that the fowls came round again. Fowls were carnivorous as well as grain-eating, and some tallow cake with cayenne pepper might be given to them with advantage. Pepper was a powerful stimulant, and aided the health of the birds, and aided their digestion. By the use of animal food and pepper, fewer fowls would be lost than was the case at present.

Mr. Scott considered that Game fowls of pure breed were the best, and they were much superior for the table. They were hardy birds, and required less attention than other breeds. He recommended the giving of animal food to fowls, and showed that there were many things in connection with housekeeping which might be given to fowls, instead of being wasted. The French people gave their fowls more animal food than English farmers did, and the production of eggs was more abundant than in this country. Mr. Gaunt had not touched upon Geese and Turkeys in his lecture, and in his opinion the breeding of these was unprofitable to the farmer. Female spring chickens were profitable, as they supplied eggs in the winter season.—(*Mark Lane Express.*)

THE AMALGAMATION OF THE PHILOPERISTERON AND NATIONAL COLUMBARIAN SOCIETIES.

I was very pleased to read in your valuable paper of the 12th inst. the Committee's report of the amalgamation of the Philoperisteron and National Columbarian Societies. Would it not be a great boon to fanciers, if the new Society would have their proceedings, and all papers read at their meetings, reported, in a similar manner to the Royal Horticultural Society's reports, in your widely-circulated paper; also, a description of all birds shown at such meetings? I think it would be the means of raising the Pigeon fancy in the eyes of the public,

and at the same time act as a stimulus to fanciers in breeding, and possibly cause some to join other columbarian societies.

First, The report states a part of the Society's business shall be to form authoritative standards for most varieties of Pigeons. I am very thankful to see this subject under consideration, and by asking every other columbarian society to forward papers containing what are considered the proper points of the birds its members breed, then we should obtain a standard of excellence for every variety of Pigeons, which would be invaluable to a young beginner, many varieties not having their points stated in any of our leading works.

Second, As regards the classification of prize lists, and the judging of birds, both subjects are being sadly neglected by the committees of poultry and Pigeon shows, simply because you can seldom find a Pigeon-fancier on their committee, and gentlemen are appointed as judges that have never been breeders or fanciers, and, therefore, not thoroughly competent to judge.

At most of our leading shows a cup or piece of plate is offered as an extra prize to the winner of the greatest number of points. In my opinion it is not a fair way of giving an extra prize, because it only brings the dealers into competition with fanciers having only a few pairs of birds, and what chance have they against the dealer who can show in every class? or else it causes two or more fanciers to unite and endeavour to obtain that which they have no chance of obtaining if they exhibit their birds separately. Such has been the case at some of our principal shows. The practice ought to be stopped. If committees intend to give an extra prize, by all means give it to the best pair of birds in the show, and then every one will have a fair chance of gaining the extra prize by honest competition.—A YOUNG FANCIER.

[Arrangements are making for carrying out some of our correspondent's suggestions.—Eps.]

DEFECTIVE-PLUMAGED POUTERS: THEIR USE, ABUSE, AND DISUSE.

I HOPE, without incurring a further accusation of undue haste, I may be permitted at once to compliment my friends, Messrs. Ure and Stuart, on the five weeks' deliberation they have bestowed upon my late article, although their commendable caution has resulted in considerable misrepresentation and some misquotation of its contents.

Both of these gentlemen have mistaken the premises of my argument, and, therefore, have advanced a criticism which does not apply. They mainly assume that I have advocated the entire disuse of defective-plumaged crosses, whereas I have simply regretted their abuse, and have pleaded their more temperate employment for strictly present purposes, nor have I hesitated to suggest a suspension of their use "for a time," and for reasons fully stated. By implication it is clear that I have not recommended fanciers to "dispense with" or "throw aside" these crosses altogether, and therefore I beg to doubt the "carefulness" with which my article has been read.

So far, indeed, from shaking my views, your correspondents supply me with many welcome corroborations, and I repeat that "the question for the breeders of to-day is not so much what may be done in crossing, but what really should be done under the present aspect and conditions of Pouters as a class."

Let me, before analysing the remarks of your correspondents, briefly re-state the facts of the case, and the deductions made from those facts. My article, then, was founded upon my observation of the last two annual shows at Glasgow. The birds exhibited on these occasions showed great progress in size, symmetry, and length of feather, and in all such matters did infinite credit to the judgment, taste, and perseverance of the Scotch breeders; but in the departments of colour, markings, and proportionate limb, there was much, very much, of undevelopment, if not of deterioration, to criticise and deplore.

These results I attributed to one-sided breeding, to a too-partial "selection" for size and form, by the too-frequent matching to birds of defective plumage, such matching clearly implying an indifference to, or neglect of, colour and markings.

As a remedy, and as a means of future progress, it was suggested to import "into the department of colour those processes of selection which had proved so effectual in the domains of size, contour, and vigour," to discard "for a time" rigorously any elements of dilution or infusion calculated to imperish the hue, and to cross instead with the "soundest colour obtainable."

I further pointed out that this could be done "without impairing the Pouter in size or symmetry; for in every colour there are many families of grand birds sufficiently unrelated to supply crosses for some time to come," and it was urged upon the sound fancier as the real triumph of his art to superadd to the advantage already acquired, and which existed in profusion, those properties hitherto neglected and deficient.

In these common-sense suggestions, as "an old fancier," one of your correspondents cannot agree, while in the opinion of the other, my "theory" (as he is pleased to term it), should not be adopted, helping, as it does, to place the "young fancier" in an "awkward position."

It is encouraging, however, to find that the facts of the Glasgow shows are not really denied, and I thank Mr. Ure for his timely advocacy of reform in the markings; and although he does not go so far as myself in regard to the deterioration of colour, there is, in his remarks, a tacit admission that colour at any rate is at a standstill.

While, however, my friends cannot accept the principle of "careful selection," as a remedy for the evils indicated, it is astonishing to notice the number of illustrations they supply in its favour. Surely, if there is one principle which more than another is cardinal, and universally admitted amongst fanciers, it is that of "selection," no matter what the property in question. Hence such phrases as "breeding true," "breeding for feather," "breeding for limb," "breeding for wattle," "breeding for head and beak," &c. And so firmly rooted is this principle, that no fancier of any experience hesitates to account for the appearance of any unexpected excellence or defect, but invariably attributes it to some ascertained or probable reversion to a previous cross; and, if in Pouters the instances of reversion are more than usually numerous in the department of colour and markings, it is owing, without a question, to that partial and one-sided selection which has had for its principal object size and contour.

I am reminded by Mr. Ure, "that many of the finest birds that have been bred in Scotland have been from Mealy, Chequer, or Sandy birds matched with birds of the standard colours. Now, where has this been denied? Surely my article was based on this very fact, together with the additional fact that the successes attending this method of "selection" for size and form, have like most successes been abused, and that so lavishly as to lead to baneful results in the department of "colour" (which is the actual question raised in this discussion, and not merely the mating of Mealties and Yellows, as your correspondent will find, when he refers to page 62 of this Journal, for January 10th).

It is also asserted by Mr. Ure, that the present grand properties of contour, size, vigour, &c., have all been developed from birds "little better than Pouting Horsemen." How has this been managed, except by "careful selection?" Again, "Yellows, for instance, bred together, soon become pale and faded-looking; but a well-selected Red improves the colour at once." What is this but careful "selection?" and if Yellows can be thus intensified and preserved from dilution, why not the other colours?

Once again. The improvement of the markings will be "easily managed," but to lengthen the limb will require both "time and skill." But by what method, if not by "selection?"

Mr. Stuart follows Mr. Ure, and further corroborates me by saying that "any good fancier who has tried the experiment of crossing a Blue Pouter and a Red, or a Mealy and a Yellow, will not repeat it in a hurry." This is a negative process of selection. And again he says, "The best method is to select two birds that with both their points combined come nearest to perfection. When we do this we do all that we are able, and it is not absurd to expect a happy result." With a belief so confiding in the virtues of selection, will it be too absurd to hope that at least some of the grand birds of Scotland may be "combined" for happier "results" in colour and markings?

Mr. Stuart is not, however, without a rival remedy to inculcate (which, perhaps, will help the "young fancier" out of the "awkward position" in which I have so unwittingly placed him), he "destroys" his mismarked birds in the nest. But what is this even but "selection?" for, clearly, if all the bad birds are selected for destruction, none but good ones will remain to perpetuate the strains; thus the reversion to bad markings will be controlled, if not ultimately prevented. This method (pardon the irreverence), might be termed "Pigeon-pie selection," suggested, as it is, by so distinguished a conservator of well-pied Pigeons.

The illustration drawn from Almond Tumblers is particu-

larly unfortunate for Mr. Ure, and affords but another corroboration of my views. Whatever use Almond-fanciers may be making of Kites, Duns, and Grizzles, it is more than certain that Almonds just now are at a standstill in regard to feather, if not actually declining; while the notoriously favourite properties of head, eye, and beak alone progress. The defects so noticeable in the Pouter are no less observable in the Almond Tumbler, and arise from similar causes—viz., one-sided selection at the will or taste of the fancier.

It will be seen, then, that my late article advances neither theory nor novelty, but merely claims a more rigid and more effective application of a principle which is the very creed of fanciers.

Whether your correspondents disagree or not with my remarks is of small moment, while they supply such excellent illustration in my favour. When we are asked to believe that Pouting Horsemen were the progenitors of our present grand race of Pouters, we can only do so by giving credit for a most persevering amount of selection for symmetry and size. We are not asked, however, to endorse a similar or proportionate development in colour, for even if we admit that "Blacks, Blues, and Yellows are all as good as they have ever been," the admission by no means involves either progression or present excellence, while it leads us not unreasonably to inquire why colour, like size and form, is not better than it has ever been, especially as its improvability and amenability to control is undisputed. In the main, colour is bad now whatever it may have been before, and its improvement by any possible means should be the aim of every artistic fancier.

But what better principle, or what better application of it do these gentlemen advance? In the lamented absence of a "printed guide," the "young fancier" is told by your correspondents to use Meales, Chequers, and Grizzles in their "proper places," to use "the right sort of Splash," to "properly match" their birds, as "it all depends upon this." What is this but selection? and supposing the "young fancier" aspires to sound colour, as well as other properties, how is he to discover the "proper places," and the "right sort" on which it "all depends." He will find but little to help him in your correspondent's remarks—little, indeed, which will relieve him from his "awkward position." To some extent he has been told what may be done, but what really should be done is, for all your correspondents have affirmed, as much in the dark as ever. To be told "that the Chequer bred from Blacks should be crossed with Blacks only" is very good advice indeed so far as the Chequer is concerned, and simply amounts to improving Chequers by careful selection, and the importation of sounder colour. But before it is put forward as advice to be followed for producing "Blacks of raven brilliancy," it may be well to consider the kind of colour from which the Chequer has been bred, the kind of Black to which it is to be mated, and how much Chequer or other diluting blood the said birds already contain. These and kindred questions are surely not immaterial if improvement of colour is really in question, and call loudly for answer before further dilution is advocated, for our present Blacks are very impoverished in tone, and so far from pretending to raven brilliancy are too frequently of a bluish, ashy, slatey, and almost dappled appearance. The question at issue is not the improvement of our Chequers or Meales, but the establishment of sound standard colour.

While scorning theory, it would scarcely seem consistent to withhold practice, and so Mr. Stuart goes a step farther, and gives us the actual method employed by the experienced breeders of Scotland, who, he says, "to the best of their judgment select such birds as they think suitable for producing the most perfect colours, at the same time keeping in view size and form." Perfect colour is therefore the primary consideration, while size and form are secondary. But, what of the results, and of the evidence of his brother fanciers? For notwithstanding that colour is very unsatisfactory; that the successes have all been in the departments of size and form; that Mr. Ure claims no development of colour; that Mr. Huie, writing on the colour question, says, on January 30th, "These facts show how colours have been mixed, but we have been working for size and shape; these being attained, we shall by-and-by arrive at the desired colour"—notwithstanding this, and much more to the same effect, we are now to understand that "the most perfect colour" is the antecedent feature of Scotch selection; while size and form are treated as subsidiary—simply "kept in view."

At last, then, the young fancier is extricated from all his

difficulties. Henceforth to produce great results in size and shape, he will match for "perfect colour," and if he is venturesome he will to obtain perfect colour match for size and shape. Simple-minded fanciers, who have been in the habit of connecting cause and effect may be somewhat staggered at this revelation, but what of that? "Practical experience is safer than theory." At least, so Mr. Stuart finds it.

Good a judge as my friend, Mr. Stuart, undoubtedly is of a Pouter, and thoroughly acquainted as he may be with Scotch fanciers, I hesitate to accept this version of their method. Either he has inverted his meaning, or a failure most signal must be confessed, for despite of all this judgment and selection for colour, it is only form that progresses.

It is pleasing to find, however, that my article has not been wholly misunderstood, and that an acceptance and confirmation of its views may be found in a late number by that earnest and successful fancier, Mr. Boyd, of Edinburgh, who is of opinion that my suggestions fully meet the case. Although I have much more to say, I must not occupy more of your space this week, but in an early article I propose further to examine the statements of my friends, and to push on a stage the subject of defective-plumaged Pouters, for the whole question of improved colour and markings hinges on the use, abuse, or disuse of such birds.—W. VOLCKMAN, *London*.

NEW BOOK.

Fowls: A Plain and Familiar Treatise on Breeding, Exhibiting &c. By JOHN BAILY. Seventh edition.

THAT this little volume has reached a seventh edition of part, and a fifth edition of the other part, is a sufficient evidence of what the public think of it. We can testify to the truth of this sentence in the preface—"it is all practical."

LIZARD CANARIES.

I WILL endeavour to answer Mr. Hawman's questions, and I hope satisfactorily.

No. 1. A high colour is not quite so much an object in a Lizard as in a Norwich Canary, but certainly to be desired; and in a Silver class a bird whose ground colour is a good mealy ought always to beat a bird whose ground colour is buff, supposing they are equal in other respects.

No. 2. Certainly not. It ought never to be shown anywhere, or, if shown, ought to be disqualified.

No. 3. Silver-spangled class.

No. 4. A decided fault. A good Lizard ought to have the following properties:—Large oval cap, square at the back. Beak, legs, and feet very dark. Head flat, large, and wide. Neck and back well and evenly spangled. Tail and wings black. The cap is the most important part in a Lizard; and one with a broken cap ought in my opinion to be at once disqualified by the Judges, no matter how good he may be everywhere else.—HOWARTH ASHTON, *Polefield Hall, Lancashire*.

LIFE OF A TAME HAWK.

PETLAND has many inhabitants. They vary in appearance. Some have four feet, others two; some are clad with hair, others with fur, others, again, with feathers; but as a rule they must be *petites* to be fit to be pets, the latter word coming from the former, and I should scarcely think a whale, or an elephant, or a giantess was ever made a pet.

There is another rule, another pet-canon—a pet must be domestic, must be tame, in order to give much pleasure. A wild bird may be admired, but its wildness prevents its being petted. Thus the kind clever dog, the wise quiet cat, the saucy yet tame Bantam, the Pigeon that feeds from your hand (especially the Pouter, playing and blowing to his master's "hua, hua"), the Bullfinch that kisses his fair mistress—all these, and such as these, make superlatively excellent pets, because of their exceeding tameness.

The tamer a pet is the more pleasure it gives, and, another great point, the happier it is in itself; and who is there that can take delight in that which is unhappy? However, there are some birds classed as wild which may be tamed so far as to become very interesting pets, and their life may be made very tolerably happy. I have written this because I have been a daily witness for many months of the semi-captive, interesting, and I think happy life of a Windhover or Kestrel Hawk.

One fine day last June, on returning home from a few days' absence, I was led, or rather dragged, by a group of enthusiastic children to see a new pet—such a favourite. But what was it? Of course I was not told at once, but made to guess and guess again, until the children's patience was sooner exhausted than mine, and each tried to get out the word "Hawk" first, for a Hawk it was; and I am afraid I shook my head, fearing scratches, bloody hands, or worse damage to the young ones. Led on further, I saw in the dim recess of a rabbit hutch, the new pet, "Jack" by name, for he was already named. Master Jack was a very yellow gentleman, with a kind of old-Indian bilious look, having tags of yellow down hanging to his feathers, and an ever-snapping beak which boded mischief, but happily was as yet soft and incapable, though desirous. He could not feed himself, but opened his mouth readily when hungry, eating heartily of small pieces of bird, mouse, or uncooked meat. Neither did he object to a drop of water from a tea-spoon; but this he did not receive cleverly, a little child remarking, "Jack is naughty, he spills his tea!" Whether Jack ever thought of his nest in the high tree, or of father and mother, or brothers and sisters, those other "yellow boys," I know not; but I incline to think he did not, for he showed no signs of pining. Ties of relative or friend hung loosely upon him, and he cared not for "the old folks at home." Perhaps he was a philosopher, if so a stoic; perhaps not. However, he fed his fill each day, and what cared he?

Presently Jack was remarked as being of an inquisitive turn of mind. His hutch commanded a view of the back door, and no one could come in or go out but he observed them, and would watch them out of sight with an odd sideways movement of his head and neck.

Jack progressed famously. On showing him a dead bird out came his talon, and he grasped it and stood on his prey triumphing; but for a long time he could not tear a bird to pieces; when he could he always began at the head. Jack now showed a wish to perch, and his wish was gratified. A perch such as Macaws are seen upon was made him, and he took to it at once, and seemed highly pleased to be no longer in a cage, but to enjoy the whole prospect, for his inquisitive eyes looked every way. A ring moved up and down the upright pole, to which was attached a chain, the other end being fastened to his foot.

But, alas! the course of pet life, like that of true love, never runs smooth. Perhaps Jack "came out" too soon, and like many an unfeathered biped, was all the worse for it, for a precocious career is beset with perils. Coming from church one Sunday morning, poor Jack was seen lying helpless on the ground, and on examination he was found to have greatly injured but not quite broken his leg. Great was the sorrow of all, and the desire to relieve the poor bird of his pain. The limb was bound up carefully, and Jack placed very tenderly in a hamper nearly full of soft hay, and the hamper put in a dark place, so that the poor pet should have no temptation to move or struggle. Three weary weeks did Jack pass thus in the dark. I hope he slept his time away. But oh! the benefit of trouble. After this calamity Jack was no longer wild. He had learned to love the one who brought him his food, and who had cheered his solitude; he would now allow his breast to be stroked, and would even permit a kiss. Once again mounted on his perch in the sunshine, care was taken, by swivels put in here and there in his chain, that he should not in future get entangled and come to grief.

The weeks now passed on smoothly enough. By day Jack enjoyed the open air, the nights he passed in the stable. Very tame became the bird; very kind, though sharp, was at times the expression of his bright black-beaded eyes. Now he would fly on the arm of a child, and ascend to the shoulder or the head. He liked his prey to be given him alive, and, seizing, killed it in a moment. He would even eat meat cooked, or pick a bone; but to keep him in perfect health he needed mouse, or rat, or bird occasionally, for from these only he could cast up pellets, as is the case with birds of his "order." Once by chance he was placed near the Pigeon pan, and instantly took a bath, which is allowed at intervals, for by his own will he would be always in the water, and in winter he has to be kept from it. The fact that the Hawk is excessively fond of bathing in and drinking water is not generally known, hence some Hawks suffer in confinement from thirst.

The extreme tameness of this Hawk was seen in his allowing the hens to feed close by him, or even a Pigeon to pick little fatty bits off a bone of his; yet the old nature was seen in his carefully hiding portions of his food under the circular

board on which his perch stands, in order to eat them another time.

Jack showed an unmistakable love of company. Thus, when in bad weather he was removed to the stable, he would get as near as he could to the dog there chained, who on his part seemed in no way to disapprove of his nearness. Placed one day very close to the dog, he was found sitting on the straw by his side. No harm arising, he was allowed to be near always. Coming into the stable suddenly, I found Jack perched upon the outstretched foreleg of the dog. It was a pretty sight, and worthy the pencil of Harrison Weir. Another time we found Jack actually perched upon the dog's back. Who shall say that this Hawk was not an interesting pet?

One day Jack managed to break his chain, and away he went into the park near, and was soon seen overhead, soaring with the wild Hawks, possibly his near relations. I counted five, he being one. Of course we concluded that our pet would never return, but waxing hungry, he did, and was readily captured. Again he escaped, and again returned. Then it struck us as his plumage was so much improved by flight, and his own happiness increased, while his tameness was in no way diminished, that Jack might every now and then have his full liberty. So we agreed to let him have "his Sunday out," that being a day on which he would be less likely to be shot. So on each Sunday Jack takes his flight, returning on Monday morning, being "an-hungered." Sometimes my son is shooting rabbits a mile from this house on a Monday, and Jack spies him, and suddenly pounces down, and is on his shoulder. To one master he chiefly devotes himself—the one who fed him in his illness; to him he will come when whistled for.

It is singular to see this wild bird settling on the chimnies or roof with my Pigeons. Odd, too, is it that when he comes home on Monday, if we have not chanced to see him return, he is at night found roosting with the fowls. To show how quick he is of eye and wing, I may mention that when on the wing, if he is shown a morsel of meat, and it is thrown towards the fowls, yet he always secures it. Jack, in a sort of dumb show, replies to his name by a peculiar jerk of his head and twinkle of his eye. Oh, that "Hawk's eye!" "Eyed like a Hawk" is no common compliment, for truly a Hawk's eye is most brilliant and beautiful.

I need hardly say that Jack has won his way into the affections of us all; and who can wonder at it? Although I find I have spoken of him in several parts of this paper in the past tense, yet I am happy to say Jack still lives, and is as tame, lively, and happy as ever.—WILTSHIRE RECTOR.

LIGURIAN QUEEN'S WINGS TORN.

LAST Saturday I was looking over the combs in my Ligurian frame hive, and when I came to the queen, I noticed that her wings were very ragged, one of them in fact was half torn away, and I am quite certain that she cannot fly. She is a queen which I imported myself from Germany last autumn, and I think the journey here has, perhaps, caused her wings to be so much torn. Do you not think, therefore, that it would be better to put the queen with comb into the box you mention, or at once into the unicomb hive, and let the bees in the old hive raise another? I think this plan would, perhaps be better, as it is said that the old queen always leads the first swarm. When I looked at the hive it was very strong, five of the combs are full on both sides, and nearly up to the edges with brood and eggs, but there are no drone eggs yet.—ALFRED FINDESEN.

[Ligurian queens which have been placed at the head of colonies of black bees, are very liable to have their wings so mutilated by their new subjects as to be thereby for ever incapacitated from safely leading off a natural swarm. We say safely, because however defective the power of flight in a wing-disabled queen, she will frequently make the attempt without hesitation, and in this case must fall to the ground and perish unless discovered by the bee-keeper, and restored to her sorrowing children. We have ourselves lost more than one valuable queen in this way, and consider the liability a very serious drawback to the efficiency of the mode of naturalising the Italian race of bees in this country by the substitution of queens. We should in your case certainly make an artificial swarm, but we should as certainly delay the operation until drone brood was sufficiently advanced to insure the early fecundation of the young queens. You may yourself accelerate this desirable consummation by placing an empty drone comb or two in the hive next to those which now contain brood, ad-

ministering also three or four ounces of liquid food per diem regularly for the next few weeks. With a stock so exceptionally strong as yours is described to be, we should have every hope of breeding drones sufficiently in advance of our neighbours' black colonies to insure a true impregnation of the young queens. The best mode of making an artificial swarm under such circumstances, is described in page 80 of "The Gardener's Almanack," but do not neglect the caution given by us in reply to an inquiry in page 216. When royal cells are formed and sealed over in the old stock, you may readily and advantageously stock the box for your unicombe in the manner described by us in page 232.]

EARLY APPEARANCE OF DRONES.

A person to whom I sold some bees a short time ago, has this morning brought me a young drone which he found crawling on the alighting board. Now I find from memoranda kept the last five years, that they never appeared earlier than May 5th. Do you suppose this stock is likely to swarm unusually early from this circumstance, or why should the queen be laying drone eggs before the hive is filled with workers.

The fallows in this neighbourhood are now yielding abundance of farina, and are fully a month earlier than I have ever noticed them before. Let us hope for a good bee year.—T. W.

[Nothing whatever can be inferred from the exceptional appearance of a young drone expelled by the workers. Whilst examining the interior of our own hives, we have already seen several instances in which the projecting cover of an isolated cell has proclaimed its tenant to be of the male sex. Queen bees, like other mortals, are not infallible, and the best of them will occasionally deposit a drone egg in a worker cell, as if by mistake; it is probable, therefore, that your drone owed his birth to an error of this kind. The season is unquestionably early, and we trust it may turn out a prosperous one.]

SILKWORM-REARING IN ENGLAND.—No. 7.

HAVING described the castle and the mode of arranging the materials in it for the worms to spin amongst, I will name a few articles which are found more or less useful in Silkworm-rearing.

The Hatching Box is intended to contain the Silkworms' eggs to be hatched. It can be made of card or wood, and should have a level bottom; its sides may be half an inch in height, and it may be 4 or 5 inches across each way for an ounce weight of eggs; but cannot well be made larger than to contain 3 ozs. of eggs. For every 3 ozs. there must be a separate box.

This box must have a kind of lid fitting exactly, like the lid of a saucepan, by entering in over the eggs. In making it, take pieces of wood a quarter of an inch square and form a frame. This can be covered with canvas, net, or other material having holes about the size of a mustard seed, and which is to be glued to the frame, and tacked if found necessary, for it must be tightly extended as for a sieve. This frame or lid is to be let into the box over the eggs, but not so as to touch or press on them; and to prevent this, four pieces of cork or wood should be placed in the corners of the box among the eggs, just one-sixteenth of an inch above their level; on these the lid will rest. The eggs in the box should not be more than one-eighth of an inch deep. The lid must have small handles or pegs by which to lift it. The little worms on issuing from the eggs make for the holes or canvas, pass on to the mulberry leaves placed above, and along with these may be lifted off and placed on sheets of paper.

The above kind of hatching box is used by many large Silkworm-rearers, but I find the following mode of construction is an improvement. Take an even piece of cardboard, or wood, 6 inches or a foot square; lay the eggs upon it to the depth of about one-eighth of an inch, and glue an edging or list of wood round it so as to come just above the level of the eggs, a hair's breadth will do. This edging will keep the eggs in their place. The frame or lid can be made rather larger, and only the canvas part will be laid over the eggs, but supported from touching them by the wood. It will be readily seen that in this way the worms will be in no way incommoded as by the wooden frame inside the box.

I have adopted a more simple method than either of the above with success, when the quantity of eggs is small, by doubling a sheet of rather stiff paper so as to form channels

or gutters thus —AAAA—. The gutters are made about an inch in height, and are kept open at top to the extent of from half an inch to an inch, by gluing down the two sides to cardboard. The eggs are placed in these gutters, the leaves are laid on the ridges, and the worms on hatching easily travel up the sides to the leaves, which can be readily lifted away without any eggs adhering to them, as would be the case if the leaves were laid directly on the eggs, by reason of the fine web silk issuing from the worms' mouths becoming entangled among the shells. Perhaps this plan would be somewhat tedious for large quantities of eggs, but I believe it to possess some advantages. The warm air of the hatching room can circulate under the gutters, and its doing so is certainly beneficial to the eggs; besides, the eggs, instead of being heaped together, lie farther apart, and thus the worms have more room to travel about, which I consider very important. If the leaves from being very small fall into the gutters, this may be prevented by laying over the ridges fine netting, by which worms and leaves may be lifted away.

The Thermometer is necessary in Silkworm-rearing, to indicate the heat of the room in which the worms are. Some persons also use a thermometer out of doors to serve as a guide in the admission of the external air to the room.

The Hygrometer is recommended by several first-rate Silkworm-rearers to point out the degree of humidity in the rearing room. It is not so absolutely necessary as the thermometer. Damp should be wholly avoided. Salt will be a good substitute for this instrument, for if placed on a saucer in the room it continues dry if the room is not damp, otherwise it becomes damp. A damp room is an improper place in which to keep Silkworms. Stagnant dampness is that which is so hurtful, and not the natural moisture of the atmosphere from rain, because the insect lives in the open air, exposed to it as well as to sun and wind.

The Microscope at the present day has become an essential instrument, not only in examining the Silkworm, but even the eggs, to discover if they be free from disease. The instrument should magnify at least three hundred times.

Sheets of paper or calico are necessary for covering the stages on which to keep the worms. When paper is used it should be tolerably stout and without gum, in order that it may dry quickly. The sheets for the stages I have described should be 2 feet by 18 inches, two covering each compartment, or sixteen to each stage. A paper without colouring matter is to be preferred; common brown paper will answer the purpose. I prefer calico if not too dear, for it will last several years and can be washed, which paper cannot be; indeed it can seldom be used again the second year. The commonest grey calico will serve every purpose, and it may be cut if desired to the full size of each compartment of the stage. The calico must be laid in water in order to shrink it before cutting, otherwise it will shrink on being washed, and become too small to cover the compartment.

Wooden or Tin Trays.—These are for transporting the sheets of paper or calico on which are the worms from one stage or place to another, when their removal is necessary for the purpose of cleaning, and to give more room. These trays may be formed of light thin boarding, well planed and even polished, that the sheets may the better be drawn off into their fresh position. Tin would answer the purpose very well, or even stiff cardboard, but I consider wood best. The trays should be made rather less in width than the compartments of the stages, because when these are arranged with the materials for the worms to spin in, the trays will have to pass between them without disturbing such materials. The most convenient size seems to be 15 inches wide, and 4 feet long. Their being less in width than the sheets of paper is of no consequence, because the worms are only to be placed so as to occupy about half the area of the stages, and as the worms grow larger the other half of them fill their new quarters. The only time the worms would have to be laid more thickly would be when full grown, at the time of moving them into their spinning retreats. The width of 4 feet admits of two sheets of paper being carried at once, besides the convenience of lodging the trays across the side rails of the stage while gathering up the worms.

Nets and Perforated Sheets of Paper.—Nets are used by many Silkworm-rearers to facilitate the work of cleaning when the worms are growing large, or after their third change of skin. The net is laid over the worms, and leaves are distributed over it. The worms pass through the meshes to the leaves, and can then be lifted up by the net, which can be secured to the bottom of the stage above by hooks during the time the dirt

and refuse leaves are being cleared from the stage beneath, after which net and worms are again let down upon it. These nets are to be made of the same size as each compartment of the stage, or eight in number. Larger would not be convenient, as they would belly too much in the centre with the weight of the worms. The meshes of the nets should be from half an inch to three-quarters of an inch square. It will be necessary to have as many nets as will cover all the stages, as they have to remain under the worms. Many persons use paper, perforated with holes the size of marbles; but I do not find it in any way preferable to nets; on the contrary, it presses too much on the worms, and all do not find their way through; besides, paper is not so durable.

Ladders or Steps.—These are to assist in reaching the higher stages of a castle. Folding steps, 5 feet high, running upon casters, would be more suitable than common ladders, as it would not be necessary to lean them against the castle. Each castle requires two, or one on each side.

Leaf-cutting Machine.—This is a box with a knife in the fashion of a chaff-cutter, and is used by large Silkworm-rearers who have many leaves to cut for the worms. A good clean sharp knife answers the purpose well on a small scale. The leaves should not be cut until wanted, as they must be given to the worms immediately, or the edges where cut soon dry, and they would then not be so acceptable.

Baskets will be necessary, or large open hampers to put the leaves in on being gathered. Some persons use sacks, and these will answer the purpose if they be emptied before the leaves have time to heat, which might be detrimental to the worms. They should not be placed on the ground, as there is then a danger of ants, earwigs, and other insects, finding their way among the leaves. On the Continent large sheets are also used for this purpose, the leaf-gatherers descending from the high trees with large apronsful of leaves, which are emptied on the sheets, carried home in a cart, on the backs of donkeys or mules, or on men's heads.

Wooden Stands are employed to support small sheets of linen or calico, on which the female Silkworm moths are placed to deposit their eggs. They are made about 1 yard square. The most simple mode of construction would be to form a frame with inch splines, nailing half-inch ones across at every 6 inches, to give more firmness, and to secure the linen more evenly. At the back of this two inch splines 2½ feet long are fixed on hinges to the top part of each side, to serve as supports, which on being opened cause the frame to take a slanting position; this is better than a perpendicular one for the moths. At the bottom of the frame in front there should be formed a sort of gutter to hold any eggs that may fall from not adhering to the linen. This can be formed by pieces of rather stout wire 4 or 5 inches long knocked into the spline at the bottom of the frame, and then bent circularly upwards in gutter form, in which the linen will lie. The linen must be evenly suspended and tacked round the sides of the frame, and can then be placed for use on a table or a Silkworm stage. This size of frame and sheet will contain easily the eggs from a thousand or more moths. It is necessary to have at least two of these stands; one for the moths to pair upon, and the other for the females alone to lay their eggs on without disturbance.

Bone or Wooden Knives are recommended by some authors for scraping the eggs from the linen before being hatched. This cannot, however, be done until linen and eggs are soaked in soft water to soften the gum by which the latter adhere. I have found that a common tablespoon answers the purpose.

Little *brushes*, or a kind of whisks, are requisite for brushing the stages clean, as well as close baskets for carrying away dirt, &c. Traps will be necessary to catch mice and rats, if any, for they are sure to eat the worms; but to prevent their mounting the posts of the castle, the bottom of these could be encircled by tin soldered round, up which they could not mount. A dredger or sieve with holes a quarter of an inch in diameter is used by some Silkworm-rearers to sift the cut leaves over the worms, and although I never have adopted the system, I consider it good, for I believe the less the leaves are touched by the hands before being given to the worms the better; besides, they can, doubtless, be distributed more equally than by hand.—LEONARD HERMAN, JUN.

perly, but were left to do as they liked during the winter. They have been fed on peas, with the addition of a little barley occasionally. Wheat is very good for them when rearing young.—L. B.

OUR LETTER BOX.

SALT FOR FOWLS (Tyro).—We do not think it necessary to give salt to fowls.

HEN LAYING SMALL YOLKLESS EGGS (Inquirer).—If you had not killed the fowl she would have become that which is called a hen-cock. She would never have produced natural eggs, and would have been that abomination in a yard, a crowing hen. All hen-cocks in fowls, and the mis-called mules in Pheasants, are found in the same state when dissected. The whole of the inside is covered with yolk of egg which escapes from a fissure or other injury.

BREEDING DARK BRAHMA POOTRAS (Old Subscriber).—Large birds may be bred from small ones, but it is always doubtful. For breeding good birds we like good birds, and have no affection for the late-hatched dwarfs. If the cross is a good one, try it by all means. April is a good time for hatching.

HATCHING PULLETS' EGGS (E. A. S.).—Yes, the first season's eggs, but not the first eggs. The later eggs of the first clutch may be trusted in every way.

COCHIN-CHINA COCK'S HEAD SWOLLEN (C. L.).—We should purge him freely with castor oil, and rub the face with cold water and vinegar every morning. It is not roup, Cochins are not subject to it. We should, while he feeds well, give him a table-spoonful of castor oil every day.

GIVING MEAT TO COCHIN-CHINAS (Lemon Buff).—Meat is not necessary at all, but if you give it, give it cooked. Raw meat makes weight, but causes mischief in every way. It induces apoplexy in laying hens, from inordinate fat. It creates all sorts of vicious and depraved appetites, which they gratify at any cost, eating the most sensitive parts of their companions' bodies. It induces a great growth of comb, and is often fatal to the hope of success.

REMUNERATION FOR REARING CHICKENS (An Old Subscriber).—It would depend partly on the time of year. If the chickens are two months old now, they would be worth 1s. 6d. each. If to attain that age in June, 1s. each, food being found.

AGE OF PULLETS LAYING (M. A. H.).—It is partly dependant on breed; thus, Brahma Pootras and Cochins lay earlier than Dorkings. If an average were taken, it would be found they lay at about six months. New-laid eggs should make now about three-halfpence each in towns.

BLACK EAST INDIAN DUCKS (Many-years Subscriber).—These, Buenos Ayres Ducks, need no especial treatment. They are not early layers, and you need therefore be neither surprised nor disappointed. You may let the Duck have part of her eggs, but you doubtless know "it is bad to put all your eggs into one basket." We believe hens are always better mothers than Ducks for Ducks. We have always found them hardy.

POULTRY IN CONFINED SPACE (C. A. J.).—We agree with what was said by "OLD FOX."

FLEAS ON PIGEONS (A Young Fancier).—If the cote and nests are kept scrupulously clean, and limewashed with a little flowers of sulphur in the mix, there ought not to be vermin of any kind. Dust under the feathers with a powder composed of equal parts camphor and flowers of sulphur.

BOOKS (S. Taylor).—You can have Brent's, "The Canary," sent to you free by post from our office, if you enclose twenty postage stamps with your address.

BELLFINCHES—MATERIAL FOR NEST-MAKING (J. A.).—Hang in the cage a net of the same material as that which Canaries have for nesting, and also placed at the bottom of the cage plenty of dry moss and hay cut 1½ inch long.

YOUNG TURTLE DOVES EJECTED (Nutchil).—The only reason that we can assign for one of the young birds being turned out of the nest is, that the nest-pan or box is too small, or that one bird is hatched a day or two before the other, and the stronger bird turns the other out of the nest. The only remedy will be to give a larger pan or box, and to watch attentively for the cause of the young bird being turned out.

HIVE COVERS (Apis).—The milk pan, doubtless, answers very well, although we have never tried it. All our hive covers are similar to the one delineated in page 17 of the last edition of "Bee-Keeping for the Many," and which we had leaves nothing to be desired.

SQUIRRELS (L. B.).—No reply has come to your inquiry whether these animals eat the grubs in oak galls, and we have no knowledge of the fact. We think it more likely that they eat the galls, for they are not carnivorous animals.

POINTS OF HIMALAYAN RABBITS (Catherine).—Himalayans are Rabbits of colour. Their skin should be dead white, save the ears, feet, nose, and tail, these should be a very dark brown; the eyes pink. We have kept Lapwings where there were many cats. We never lost any, nor do we think they would take them.

POULTRY MARKET.—MARCH 25.

THERE is a great scarcity of good poultry, and prices have gone up. We cannot guarantee their continuance, but good qualities will sell well for some time.

From observations taken near London during the last forty-one years, the average day temperature of the week is 56.5°; and its night temperature 36.2°. The greatest heat was 79°, on the 7th, 1859; and the lowest cold 21°, on the 6th, 1851. The greatest fall of rain was 1.19 inch.

CALADIUM CULTURE.

OF the many stove plants now cultivated for the beauty or gracefulness of their foliage, few excel the different species and varieties of *Caladium*, and the majority of these being of tolerably easy cultivation, they are very generally grown. Although directions for their successful cultivation have appeared from time to time in the pages of *THE JOURNAL OF HORTICULTURE*, still, a few remarks suggestive of the mode of treatment required, may at the present time be acceptable to some of your readers.

Supposing that the plants have awakened from their winter's slumber refreshed and invigorated, the rhizomes or rootstocks plump and fresh, and just beginning to emit roots, then is the time to have them turned out of the pots in which they have been wintered, and either divided into small pieces with two or three crowns to each, or retained whole according to the wishes or requirements of the cultivator.

Pots from 3 to 5 inches in diameter, according to the variety or the size of the rhizome to be introduced, are large enough to use for the first potting. Crock such well, as good drainage is indispensable from the first. A compost of two parts loam, one of peat, one of leaf mould, one of decayed sheep or cow dung, with a liberal addition of silver sand, well incorporated and passed through an inch sieve, is a good soil to start *Caladiums* in.

In potting, place the rhizome low enough, so that it can be covered with half an inch of soil. Press the soil but very little; a smart tap on the bench will almost be enough.

After potting, place the pots in a gentle bottom heat, where an atmospheric temperature suitable for the majority of stove plants can be maintained. Give enough water to moisten all the soil, but not to saturate it. In a few days the roots will have reached the sides and bottoms of the pots, while the upper portion of the plants will only have appeared above the soil.

When one or two leaves appear on the plants it is a good time to shift these into larger pots, using soil of a similar nature to that previously employed, but in a rougher state. After this potting bottom heat can be well dispensed with, and the plants placed in the stove. Shading from bright sun is highly necessary.

As the plants grow, some of them can be repeatedly shifted into larger pots, with the view of forming large specimens, or several may be placed round a large pot at the second potting for the same end; but if such be intended for exhibition, the chance is that the pot may be excluded on the ground of its containing a plurality of plants. I consider pots 12 inches in diameter large enough for growing good-sized specimens; in such I have grown plants of *Caladium Chantini*, *Wightii*, and others 4 feet in diameter. I much prefer the plants, however, in pots from 6 to 9 inches across.

Few plants delight more in an abundant supply of water at the roots; and such must be unsparingly given, other-

wise all hopes will be blighted. I have sometimes found it necessary to have a saucer containing water for the pots to stand in. When the pots have become full of roots weak manure water may be applied with great benefit twice a week. An abundant supply of moisture must also be maintained in the surrounding atmosphere by wetting the paths, stages, &c., or by means of evaporating troughs or other appliances. A little soot or guano mixed with the water in the trough will help to enrich the atmosphere, and act as a stimulant to *Caladiums* and most other stove plants. Most practical men are agreed that a humid atmosphere moderately impregnated with ammoniacal gases is one of the best preventives against the appearance and increase of parasitical insects in heated structures.

If the leaves of *Caladiums* are to preserve their brightness they must not be syringed overhead; for however careful the selection of water may be, applied in this way and habitually, a sort of incrustation will eventually form over the leaf, and render it inaccessible to atmospheric influence by entirely choking up the pores.

The most inveterate insect enemy to *Caladiums* is the green fly, which can be kept under by cautious, judicious, and frequent applications of tobacco smoke, or by the administration of an infusion of quassia chips of the strength of three or four ounces to the gallon of water; the plants being dipped into the solution, or this being applied with the syringe.

The principal use to which these plants may be put, otherwise than the decoration of the stove or other heated structure, is as table plants. No plants are more prized here at table than some of the varieties when grown in pots 5 or 6 inches in diameter.

Perhaps the greatest difficulty experienced by those who grow *Caladiums* is in the keeping of the rhizomes in a fresh state during winter. Their proneness to decay is now generally acknowledged, and considerable difference of opinion prevails amongst practical men on this important point. One maintains that the soil in the pots should be kept moist, another maintains that it ought to be kept dust dry, while a third party thinks a lower temperature than that kept up in the stove will prove beneficial, by insuring a more perfect state of rest, as assuredly it will, and that more lasting than desirable. In my opinion more *Caladiums* are lost during winter from being imperfectly ripened in autumn than from all other causes, excluding, of course, a low temperature.

The gradual withdrawal of water when the earliest leaves attain a yellowish tint will help greatly to hasten the ripening process; keep the plants in the warmest part of the house, so as to compensate for declining solar heat, and, finally, when the leaves have all withered, place the pots on their sides on the floor of the house. The moisture supplied by the floor and the atmosphere will be enough to satisfy all demands till the middle of February or beginning of March.

To recapitulate—the principal points to be attended to for the successful cultivation of *Caladiums* are giving rich soil, potting loosely, giving abundance of water occasion-

very manured, shading from bright sunshine, and keeping the rhizomes in a stove temperature during winter.—J. A., *Wallhouse Gardens*.

MERITS AND DEFECTS OF CENTAUREA CANDIDISSIMA.

I can fully confirm what Mr. Record states with respect to the disease in *Centaurea candidissima* (see page 219), and, indeed, can go a step further, and say that with me the plant has shown disease when in a single row. The first symptoms of the disease appeared here in 1864, and the plants were so much affected by it in the following year that I have since grown the *Centaurea* but little. The tips of the leaves were crumpled and decayed, and this decay continued until but little of the plant was left, and it was, of course, useless for ornamental purposes. Single plants are sometimes attacked in a similar manner, but not so generally as those planted in lines or masses. This evil, coupled with the fact that the plant does not, under the best management, increase so quickly as many others, will go far to keep it from being so much used as it would be did such drawbacks not exist, for when it does well nothing can be handsomer. The gracefully recurved leaves when fully developed, and what is of more consequence than all, its paucity of flower stems, give it a decided advantage over all other plants of its class when it is well grown. I would not have said this much in favour of the *Centaurea* had *Cineraria maritima* been less apt to run to seed; but its tendency to do so, and the disfigurement its foliage receives if any attempt is made to prevent seedling, greatly detract from its beauty. For my own part I confess being unable to overcome its tendency to run to seed. The hardness of the two plants is about equal, but the *Cineraria* is much more easily propagated, or rather it affords cuttings in greater number, and these strike freely enough when allowed time.

Another great disadvantage of the *Centaurea* is its liability to die when taken up in autumn. In most cases we have lost fully three-fourths of the plants so taken up between the period of their removal from the ground and the following March, the consequence being that few cuttings were to be obtained in spring, although any that can be had then strike very freely. One or two seasons I left some old plants in the beds, but the disease in one instance, and the severity of the winter in another, were fatal to them; but I see that four plants which had formed the centres of four elevated beds, and which were left out in the autumn of last year, are as fresh as in October, and each plant will furnish a number of cuttings. This would seem to indicate the propriety of trying to grow a few plants in some sheltered dry spot, on purpose to propagate them in spring. Most likely in a dry stony soil plants would be preserved through the winter with very little protection; these I have just referred to had none. I imagine that this plant in its natural state must occupy a high and dry situation, possibly some rocky promontory or similar position, as the moist stagnant air of our forcing houses seems fatal to it in winter, and it is not improbable but more losses have been sustained in consequence of the plant being too much coddled than by a contrary course.

As to the respective merits of spring and autumn propagation, I can offer but little opinion. When cuttings can be had and put in during the spring, roots are formed more speedily than in autumn; but my experience would say, Try both plans. If cuttings can be had in September, take them off and insert them in boxes or pans in an airy place, but not in the full sun; artificial heat, I think, is not wanted at this time. One precaution in putting in the cuttings ought to be strictly attended to, and that is, to be sure not to insert the cutting so deeply as to bury the heart, otherwise the cutting perishes. I believe that more losses occur in this way than most people suppose. When the dull days of autumn fairly set in let the cuttings have all the sun and light possible; a shelf near the glass, where water but seldom reaches them, is one of the best places; but so capricious is this plant that although sometimes almost every cutting will grow, at times the failure will be almost total. In spring there is a greater certainty of cuttings becoming plants, but the number of cuttings at this time is far from plentiful, growth during the winter being slow. I am certainly disposed in future to see what can be done by letting a few plants remain out of doors all winter in some suitable spot.

Having already remarked that the *Centaurea* is not so apt to

run to flower as the *Cineraria*, it will, of course, be understood that it produces seed less plentifully, so that we cannot thus increase it to any great extent; but probably when we treat it the same as the bedding *Calceolaria*, we may have it in greater abundance. For the last three years I have thus treated *Centaurea gymnocarpa*, and with perfect success, at least so far as propagation is concerned, for the plant is a more robust grower, and furnishes cuttings in abundance, and these put into a cold pit in sandy soil by the middle of October, or earlier, make good plants by the usual planting-out time, the beginning of May. The tendency, however, of plants so raised to run to seed, and their furnishing little or no foliage, are great disadvantages; otherwise the free growth of this plant, and its graceful habit, render it superior to *C. candidissima*, although its foliage is not so white.

Cutting off the flower stems will not prevent *Centaurea gymnocarpa* running to seed, but plants from cuttings struck in spring are not so apt to do so as those from autumn-struck cuttings, and with me young plants of this *Centaurea* running to seed early in the season are quite useless, and dwindle off or die. *Cineraria maritima*, although persistently producing flower stems notwithstanding repeated cutting-off, does not die under the operation, neither does flowering occasion the death of the plant, as in the case of *Centaurea gymnocarpa*, which in this respect somewhat resembles a biennial.

Probably the most useful plant of the three is the *Cineraria maritima*, and it is also most easily multiplied. Its greatest drawback would appear to be the late period of the season at which cuttings arrive at a proper size; in all other respects this plant may be said to possess advantages which the others do not. Growers who have been more successful with *Centaurea candidissima* may think differently, and when that plant is free from disease, and can be propagated as easily in equal number, I will readily give it the palm, but hitherto in most places I am acquainted with this has not been the case. The different views taken by those who speak of its propagation are so conflicting, that it is reasonable to suppose that even the most successful growers of it have now and then their reverses and disappointments.—J. ROBSON.

NEW GLASS STRUCTURES FOR GROWING FRUIT AND FLOWERS.

The treatment (referred to in my remarks on page 238), which I conceived necessary for Peaches, Nectarines, and Apricots, rendered, as I supposed, half-hardy by impairment of constitution, was that of the valetudinarian. I screened them from cold cutting winds, at the same time giving them sufficient air at night, as well as in the day, keeping as near nature as possible. I luckily had some of these trees growing by themselves, offering fair opportunities for being experimented on. I adopted a simple but effectual mode of screening these trees, thus preventing the heat generated by the earth and sun from being rapidly carried away. This protection consisted in driving bars (grooved on the opposite sides, and previously boiled in creosote), into the earth at stated distances. Into these grooves 21-oz. sheet glass, 20 inches by 15 inches, was slipped, the screens thus formed being from 5 to 10 feet in height, of a diameter according to the size of the tree to be enclosed. A space was left for a door, and a close net was thrown over the top to keep off frost.

This plan answered so well, that in the course of ten days a most marked effect was produced on the foliage; from the exposure to light on all sides, the leaves became of a dark green, and very large, also free from anything like blotches. The fruit set thickly, and continued to grow without any drawback, until it thoroughly ripened. The Jefferson Plums, three dozen on one tree, and four dozen on the other, were most delicious, and not deformed by insects. A gardener who came from Wolverhampton on purpose to see these experiments, said, "If these are Plums, I never tasted a Plum before." The flavour of the Peaches was brisk and piquant, different from those shut up at night, or even those ripened on walls. One thing which astonished me most, was the perfect ventilation. As there was no opening, except at the top, it might have been imagined the air would become stagnant; but instead of this it was in constant motion. The average temperature inside these screens was from 10° to 15° Fahrenheit above that of the external air. The hotter the air the more rapid the circulation, the heated air ascending at the sides, and the cold air falling in the centre. If the soil be covered with coal ashes

the circulation of air is more rapid; the thermometer being placed on the soil thus covered marks a temperature of 5° higher than when placed on the common soil.

My first idea was to erect these screens about 3 feet from a common wall, and plant the trees against the glass, training them to galvanised wires, but so tying as for them not to come in contact with the wire. A great heat is thus obtained during the day, the thermometer sometimes standing at 99°, shaded from the sun; but as the temperature often went down to 40° and 35° at night, I imagined the extremes to be too great for the health of the plants.

I found the hexagonal form of structure produced a more even temperature, and no form that I have yet tried equals this, not only in economy of structure and space, but in giving health and vigour to the trees.

As I have now decided on this form, I am building several of these cylinders. As yet I have not gone beyond 10 feet in height, and 7 feet in diameter, but there is no reason why they should not be 12 or 15 feet in height, and when the inside surface is covered with Peaches, Grapes, or even Roses, it will have a very beautiful effect. Many things have come out in practice which I had never thought of when I first drew the plan of these structures on paper, but everything tending to even a more satisfactory conclusion than I had first conceived possible—real quality both in the leaf and fruit, through the increased temperature and the constant circulation of air, being one of the chief features.—OBSERVER.

MY ORCHARD-HOUSE JOURNAL.

I OUGHT, perhaps, in writing my simple (I fear too much so) orchard-house remarks, to say that the house I allude to is 100 feet long, 24 feet wide, and 12 feet high in the centre; its sides, nearly 6 feet in height, are glass to the ground, and this gives the interior a most bright and cheerful aspect in sunny weather. This is filled with Peaches, Nectarines, and Apricots. My Cherry house is 60 feet by 11, and is devoted to Cherries only.

March 21st.—Guigne or Heart Cherries and Bigarreaus, mostly in full bloom; the trees are all pyramids, covered with their snowy flowers, and are like pyramids of pearls. The exceptions are some late kinds, such as the Late Purple Guigne, and the Florencé. The Duke Cherries, except Empress Eugénie, have not yet opened a bud. It is curious to find some of the kinds of Bigarreaus that do not ripen till two or three weeks after the May Duke, in full bloom nearly a fortnight earlier than that sort. My Cherry house has given me Lettuces with fine hearts all through February. Bees abundant to-day.

March 23rd.—Apricots in myriads, as large as horse beans. It is strange that "OBSERVER," see page 237, does not succeed with standard Apricot trees planted out; his soil I know is iron clay, mine is stiff calcareous clay; but as he succeeds with them in pots in soil of the same nature, his standards ought to do well. I fear he has paid more attention to his standard French trees than to his Apricots, and has not given them so good a position. Here some low standards planted in the central border of a house 24 feet wide, the soil undisturbed, and quite hard, are full of fruit, and I fully believe that the centre of a house of like dimensions planted with standards or half-standards, and the soil kept solid, would, without any risk of failure, produce annually large crops of the finest fruit, and no fruit can surpass the Apricot ripened in an orchard house.

March 24th.—Cold and windy, with frequent storms of hail, rain, and snow, and gleams of sunshine. The orchard house is closed, and is a sort of elysium, thermometer 65° to 70°, some Wallflowers in No. 12-pots, filling the house with their delicious perfume. They are all double, with large spikes of flowers varying in colour from bright yellow to dark brown, such as we used to call "Blood Wallflowers." They were all raised from German seed. Twenty-five sorts are named in the list. They come tolerably true to name. It would seem, judging from their appearance, that they have been crossed with the Brompton Stock, their leaves are so large and succulent, and their perfume seems to be a compound of the Stock and Wallflower; it may be fancy. My plants were raised last April on a gentle hotbed in the open air, and planted out thinly in May. They require room, as in a rich soil they become very bulky by the end of summer. In November those for the orchard house should be potted into 10-inch pots, which should be plunged in tan or cocoa fibre in the house, to keep their roots safe, and remain plunged till the middle of March.

Those for the open air should be potted into 6 or 8-inch pots, protected during the winter, and planted out in March, if mild weather. They are too succulent to resist the severe frosts of winter in the open air. I have diverged from fruit to flowers, but German Wallflowers are an orchard-house luxury but little known, and my orchard-house journal is a full stream, which will overflow and form streamlets.

March 25th.—Frost last night severe, 11°; in the orchard house, with a pan of charcoal lighted at 8 p.m., 1°. The young fruit of Apricots will not bear more than 3° or 4° of frost without injury, even in the dry climate of the orchard house. The blossoms in their early stage will bear from 5° to 6° with only partial injury, but as soon as the petals and calyces have fallen the young fruit are very tender.

March 27th.—Pears and Plums in full bloom. When one compares them with those out of doors, many of which are on the point of blossoming, and reflects that for two entire months to come we are liable to have frost, and that one of a little extra severity may destroy the crop, the comfort and pleasure of orchard-house culture is fully appreciated.

March 29th.—A cold wind and bright sun, the house closed at 2 p.m., at 3 the temperature in the shade 75°. Peaches have set freely, are as large as small peas, and crowded thickly on every shoot. Bees abundant, but seemingly not happy; the pollen is all gone, the nectaries empty, and they seem to be looking for something they cannot find, their tone is sharp, and not that satisfactory humming heard a few days since.

March 30th.—Frost severe last night, register in open air at 22°, in orchard house 34°, with a pan of charcoal lighted at 8 p.m.—T. R.

WHERE ARE FLOWER POTS TO BE HAD?

AMONGST the many advertisements in the columns of this Journal, but rarely indeed the eye falls on one informing us where flower pots are to be purchased, although these are so essential in almost every garden deserving of the name. Moreover, the flower pot very often is called into requisition when there is no garden at all. Why this absence of information should be, is difficult to understand, as other articles much less extensively used are announced from various quarters. Assuredly this cannot arise from any want of enterprise on the part of the manufacturers, yet they make little or no effort to bring their wares under the notice of the gardening world, and such neglect is proportionately injurious to those who want them.

A short time ago I had to look backward over a long series of numbers of this Journal to find an advertisement announcing where flower pots are manufactured, while things not nearly so extensively used are presented weekly to our notice. Neither is the want confined to private individuals, for I happened to know of a London nurseryman whose consumption of flower pots during the year must be immense, nevertheless he has to send upwards of 150 miles for them. Assuredly this ought not to be; and it would be a great boon to many who, like myself, might want £10 or £20 worth during the year if we knew where to order them from, without being obliged each time to ascertain whether the last place from which we had them still exists.

I hope, therefore, you will stir up the memory of your flower-pot-manufacturing friends, and invite them to tell us where good well-burnt pots are to be had, and at what price they can be delivered by railway, &c.

I also hope some of your correspondents will point out what they consider the best form for flower pots, the other points of excellence required, and such particulars as will place them at least on a par with other things in everyday use, for assuredly there is no one to whom the ornamental gardener is more indebted for the aid afforded him than to the potter, and the latter is very remiss in not making his wares better known.—L. M. N.

[We cannot aid our correspondent further than by thus publishing his letter; and we are quite aware that any potter who will make known through our columns flower pots at a moderate price, of less offensive colour, and less coarse than those usually vended, would obtain a large sale.—EDS.]

BELLADONNA LILIES.—In Jersey it is the custom of gardeners to cut down the leaves of the Belladonna Lilies in June, as they say, to make them flower. Whether cutting the leaves

produces the effect or not, I do not know, but I do know that when they have been cut off in this manner the plants have flowered profusely in the autumn.—E. W.

THE GREAT INTERNATIONAL EXHIBITION AT GHENT.

THIS, the fifth at intervals of five years of the great flower shows for which Ghent is so celebrated, commenced on the 28th of March, and remains open until April 5th. A more appropriate place than Ghent could not be found, inasmuch as so many valuable collections of plants exist in the immediate neighbourhood. The great establishments of M. Louis Van Houtte, M. Ambrose Verschaffelt, and other cultivators, contain a very large number of plants of extraordinary size, which can be sent a short journey, but could not be transmitted to a great distance without great risk and expense. The wonderful collection of plants brought together at this early period of the year, for it really formed a colossal spring show, was something to be remembered. We shall attempt a brief description of the Exhibition, but to do it justice an entire number of the Journal should be given up to it.

The interest this Exhibition has excited may be somewhat judged by the fact that 120 Judges were invited from various countries, and almost all were present. England sent 15, Austria, 3, France, 35; Russia, Belgium, Germany, and other countries contributing the rest. Here could be met the great men whose names are household words amongst horticulturists, called together to award the numerous honours which were so eagerly competed for.

Everything was arranged in readiness for the Judges by the morning of the 28th, and that day was devoted to judging. The Exhibition was opened on the 29th by the King and Queen, and the Comte and Comtesse de Flandre, who took a warm interest in the Exhibition, and frequently expressed their admiration. Several of the most eminent horticulturists and botanists present were introduced to their Majesties, and Mr. Henry Veitch was specially sent for to attend their Majesties, and receive their congratulations on the new plants shown by his firm.

Their Majesties and the Comte and Comtesse de Flandre came purposely from Brussels; and the Mayor of Ghent, the Comte de Kerchove de Denterghem, who is the President d'Honneur of the Royal Agricultural and Botanical Society of Ghent, took a warm and active interest in the Exhibition, and his courtesy to all calls for special acknowledgement. Will the time ever come when in England we shall see the Royal family, and those high in authority, giving such warm and practical aid in the advancement of horticulture, and placing it in the same high position amongst the arts exhibitions as it holds in Belgium? Especial acknowledgements are due to M. Vandennecke de Lembeke, the President, to M. Charles Leirens and M. E. Claus, the Secretaries, and M. R. D'Huyvetter, the Treasurer, and the able Executive Committee. All the arrangements seemed to be perfect, and there was no confusion whatever.

Their Majesties and the Royal family were received by the Burgomestre, the Comte de Kerchove; M. Vandennecke, and M. Ambrose Verschaffelt, who accompanied the Royal party through the entire Exhibition. In the evening a grand banquet was given to the Judges and Council of the Society, at which the Comte de Flandre presided, and their Majesties and the Comtesse de Flandre were also present. As Englishmen we are not always easy to please, but there was no room for grumbling here. It was a magnificent scene, and the arrangements perfect.

The Exhibition was held in the Hotel Casino, a fine building devoted to fashionable promenades, concerts, &c., where there is a very extensive permanent building comprising a very large salon, staircases, and anterooms; and passing out on to the staircase leading to what we may call the Floral Hall, a very large building only completed in time for this Exhibition, and, for such a purpose, what an Exhibition met our view! No formal straight tables to meet the eye, but the large space was laid out as a parterre, and all round the building were huge banks of magnificent Palms, tree Ferns, and other ornamental plants, some of them fully 20 feet high. Glorious tree Ferns and giant Palms were dotted here and there, and then came banks of Azaleas, Camellias, and other flowering things. It was a grand scene, and there was only one fault to be found with

it—the building, large as it is, was too small. The writer of this tried at least a score of times to hunt out all the treasures of the Exhibition, but it was a labour to do so; there was so very much to be seen, and the plants were in some instances so much crowded. A very large number of plants which richly deserve notice must be passed by.

How the stars of Belgian horticulture shone in all their glory here! Those giants amongst nurserymen, Van Houtte, the Verschaffelts, the Van Geerts, and many others, sent their colossal plants and rare treasures; and some of the private collections, such as those contributed by Le Comte de Kerchove, President Vandennecke, and other private growers, were sufficient to make a large exhibition. To give some idea of the size of many of the plants sent, we just name that the Botanic Gardens here, of which M. Van Hulle is the chief, contributed an extraordinary lot of fine plants. Some of these were 30 feet high; one grand Palm was 25 feet high, and fully 30 feet through. M. Ambrose Verschaffelt contributed a vast collection, and was the winner of fifty-three gold and other medals. His superb collection of Palms contained a specimen of *Phœnicophorum sechellarum*, 8 feet high, and with grand foliage; a *Thrinax elegans*, 9 feet high; a wonderful plant of *Cibotium regale*, and a very fine example of *Latania Jenkinsiana*. We very reluctantly are obliged to pass over many other wonderful plants in this and M. Van Houtte's extremely fine collection, where also we noticed another remarkable specimen of the Thief Palm. M. Van Houtte was also a most extensive exhibitor, and carried off a large number of medals. In the Comte de Kerchove's collections we noticed a wonderfully fine plant of *Phoenix pectinata aurea*.

Standing again on the balcony looking to the vast flower garden beneath, what a glorious sight it is! those grand banks of Azaleas resting amongst those giant Palms and stately tree Ferns. Then there are huge banks of stove and greenhouse plants in flower, many of them very much superior to what we expected to find, and a very marked improvement in their culture has taken place within a few years. Glorious Acacias of great size and beauty, huge tubs of *Calla æthiopica*, each with about thirty blooms, and a host of other things are easily recognised. Away in a westerly direction we trace an edging of lovely Lily of the Valley, and from well-grown Mignonette and Heliotrope rises refreshing fragrance. Those grand masses of Azaleas, what a brilliant combination of colours! the free use of whites and softer colours toning down the brilliant hues of others. Nearly every plant forms from half to two-thirds of a globe, and on short stems. There is no trace of the pyramidal form generally adopted in England, and one is not a whit more formal than the other. In a small state they make most suitable decorative plants for the table and greenhouse. Round about these are large banks of Camellias, and what plants they are! Some 5 to 6 feet high, most symmetrical pyramids, and in admirable health, with rich green foliage, and densely flowered. There is as wide a difference between the ordinary Camellias of English gardens generally and these plants, as between Turner or Veitch's specimen Azaleas and what are often sold by auction. We have much to learn in Camellia-growing, and we cannot do better than take a leaf out of our Belgian friends' book in this matter. Do we not give them too much light and air sometimes, and not sufficient water and stimulants at others? This subject is worth looking into, and we will very soon recur to it. Anything finer in Camellia-growing could not possibly be seen.

We shall next week give a report of many of the leading features of the Exhibition.

TOBACCO FUMIGATION.

OBSERVING in your pages a mode of smoking greenhouses to destroy green fly, allow me to suggest one a little different, and practised here for years with complete success. Instead of charcoal use thick blotting paper steeped in a solution of nitre, and carefully dried, and when used rolled up in layers alternately with tobacco paper, damp. Do not make the solution very strong, as then the paper would consume too rapidly. An old broken flower pot will answer quite well to burn the material in. I adopted the charcoal plan formerly, and nearly suffocated myself with the fumes.—CHARLES GUTHRIE, *Tay Bank House, Dundee*.

THE VARIEGATED JAPANESE HONEYSUCKLE flowered freely on the west wall of my house at Gipsy Hill last autumn. The

flower and its perfume very much resemble those of the Evergreen Honeysuckle.—W. W. T.

MR. WILLIAM PAUL'S SHOW OF SINGING FLOWERING PLANTS.

THIS Exhibition opened on Saturday last, and will continue till the 11th instant. It is held in the Eastern Conservatory Arcade in the Royal Horticultural Society's garden at South Kensington, and whilst totally different in its arrangement, and to a considerable extent in the subjects employed, from the display furnished last year by Mr. W. Paul, it is equally charming and effective, and no one who has an opportunity should miss seeing it.

Commencing at the farther end from the Conservatory, on the right is a bank of plants some 12 yards in length, consisting of Rhododendrons, Azaleas, Lilacs, Double-flowering Peaches, Deutzias, Clematises, a fine variegated Hydrangea, Correas, Cinerarias, and a variety of other plants of different heights, arranged not to produce a flat or uniformly sloping surface, such as we frequently see on exhibition stages, but one diversified by the introduction of taller plants among those of less height, in imitation of hill and dale in nature. This is the idea which Mr. W. Paul has endeavoured to work out, and we think he has done so most successfully.

The next group is one of Acacias, among which *A. Backhousiana* and *A. eriocarpa* are conspicuous as free-flowering handsome kinds, together with *Cytisus Atleanus*, the whole edged with Lily of the Valley. Near this is placed a standard *Genista purgans*, with a head forming one mass of golden blossom. Such a plant would form a highly ornamental feature on a lawn.

Next comes a splendid group of Tulips. Of these a few of the most conspicuous are *Roi l'épin*, white and crimson; *Fabiola*, purplish lilac and white; Standard, gold-striped and crimson; *Couleur Cardinal*, red; *Reine des Cerises*, white and crimson, very beautifully striped with gold; *Bride of Haarlem*, white and deep red; *Rose Gris de Lin*, very distinct, soft rose and white; *Florida*, good, distinct, white striped with purplish violet; *Ariadne*, fine crimson; *Keizerskroon*, the *Tournefols*, and the *Pottebakkers*.

A group of Heaths adjoining the Tulips is particularly worthy of attention, as containing magnificent examples of *Erica Wilmoreana* with spikes 18 inches long. Then comes a long stage of Camellias, with four rows of plants in small pots in the front, and larger specimens at the back. Small as the plants are, most of them are in beautiful bloom, and as it is rarely that so numerous a collection both of new and old varieties is brought together at one place, they will be of very considerable interest to cultivators of this gorgeous-flowering shrub. A few of the most remarkable are *Lavinia Maggi*, with large beautifully striped flowers, like a flaked Carnation; *Belle Jeannette*, rosy crimson, with a faint white stripe in the centre of each petal; *Innocenza*, milky white, with more substance in the petal than the *Double White*; *Princess Frederick William*, very free, Carnation-striped; *Cup of Beauty*, very fine, white; *Contessa de Hainaut*, lovely blush, finest of its colour; *Bicolor de la Reine*; *Souvenir d'Emile Defresnes*, crimson, with a white band up each petal; *Monteroni*, finely copped, pure white, petals of fine form; *Princess Bacchiocchi*, scarlet crimson, more intense in colour than most of the red Camellias; *Prima Donna*, blush, very delicate in colour; *Rosca spectabilis*, bright rose, very beautiful; and *Etoile Polaire*, a lovely miniature crimson, striped with white.

The next group is one of Aucubas, both green-leaved and variegated, male and female in flower, and many of the latter in berry as well, besides several other variegated Japanese plants. Pot Roses occupy a stage between these and similar group of Aucubas, and among the Roses a specimen of *Madame Boll* is very fine. *Charles Lefevre*, *Madame Moreau*, and *Lord Macaulay*, the last-named very bright in colour, are also very striking.

Hyacinths, upwards of two hundred in number, fill a stage similar in length to that occupied by the bank of miscellaneous flowering plants at the entrance, and form the finest display of that flower seen near London during the present season. The spikes of many are magnificent. *Solfaterre*, crimson scarlet, is remarkably fine; so are *Argus*, dark blue with a white eye; *Duc de Malakoff*, fawn; *Snowball*, white; *Van Speyk*, *Von Schiller*, pink, striped with crimson, forming a very close pyramid; *Haydn*, mauve; *Gigantea*, *Charles Dickens*, *Mont Blanc*, *Ornament de la Nature*, very delicate rose; *Garrick*, light and dark blue; *Lina*, beautiful red; and *Lord Macaulay*, crimson, broad petals. *Bird of Paradise* has no less than eight spikes from a single bulb, and *Carnegiea* five, forming masses of bloom which would be valuable for general decoration in conservatories, though of course they would not pass muster in a florist's point of view.

Retracing our steps from the Conservatory by the front of the arcade we find a series of groups, some arranged on small tables in the spaces between the windows, others on the floor, and consisting chiefly of Hyacinths, Narcissuses, Cinerarias, fine-leaved Pelargoniums, and Euphorbias. There is also a small group of the beautiful *New Double Scarlet Thorn*, which is valuable for forcing in a small state, and when large will, doubtless, prove a highly ornamental tree for out-door decoration. In the groups on the small tables just referred to the new Hyacinths are chiefly to be found, and of these Mr.

W. Paul was this year the most successful exhibitor, taking first-class certificates for *King of the Yellows*, the finest flower of its colour and the best Hyacinth of the year; *Grand Monarch*, pale blue, striped; *Clio*, pale blue with a white centre, and dark blue blotches on each segment, decidedly good; *Couronne des Bleus*, and *Autocrat*. *Seraphine*, delicate grey, with a carulean tube, is also very pretty, and promises to be fine for exhibition.

Narcissuses are unusually fine, some of the spikes having no less than nineteen flowers; and of Euphorbias there is a fine display, though some had suffered from the journey. The best are *Hyacinthiflora grandiflora*, white; *The Bride*, white, tipped with red; *Corsicans*, peach; *Acuminata*, fine reddish scarlet; *Delicata*, pink, tipped with white; and *Coccinea major*, red. There are likewise boxes of cut Roses, including fine buds of *Madame Falcot*, *Madame Margottin*, a new, very sweet, and very double pale yellow Tea; *President*, very fine; *Lady Suffield*, very fine form; and *Globosa* with petals turned over, forming a crimson ball. In a group of fine-leaved Pelargoniums we noticed *Jason*, with beautiful golden leaves, one of the finest of its section, and *Prince Silverwings* and *Snowdrop*, the latter with a broad white edge, and a large finely formed scarlet flower.

The greatest credit is due to Mr. W. Paul for his fine exhibition, and that it will be highly appreciated by those who may have the good fortune to see it we have every confidence.

BANGALORE HORTICULTURAL FÊTE.

THE Bangalore Horticultural Fête, which took place yesterday (December 31st, 1867), was everything that could be desired on the part of spectators, with one omission, of which more anon. At an early hour, 3 p.m., carriages, "shays," and "shanderydaws" commenced to rattle along the two-and-a-half-mile road that leads from the Cantonment of Bangalore to the Government Lal Bagh Gardens, and up to five or half-past five o'clock, the stream of vehicles still continued, reminding one of a Derby day on a small scale, or a Presidency uproar on a large one. A portion of this road was well watered, and as the drive is a pretty one, the time *en route* passed pleasantly in such racing as the road afforded. At this sport notorious hack gharrys of Bangalore appeared to be adepts after their own peculiar fashion, and it was amusing to see the dusky half-naked *Jehus* drive their skinfulls of carrion into a wild "spurt" of fifty yards, which inevitably terminated in a dead stop and a cloud of dust, thick as the smoke of a sixty-eight pounder. At the gates of the garden, and along the road leading to the tents, the Commissioner's escort of Mysore horse was stationed and looked very well in its scarlet apparel, though the troopers' appearance would be much improved if they would cease to tie their puggies round their jaws with napkins which gives them the laughable effect of being afflicted as a body with toothache and tie doloureux. The tents, which were considerable in extent, and connected by passages, to which matting spread overhead afforded a protection from the sun, were pitched on a level piece of ground opposite the bandstand, and were gaily decorated with flags and streamers.

Inside, the show of Flowers, Vegetables, and Fruit, and especially the latter, exposed for exhibition on long rows of shelves, was something worth seeing in England, and perfectly astonishing in this country. Indeed a basket of Apples, the property of a native gardener, and which obtained the first prize, was of such superlative excellence, that your correspondent can truly say he has never seen a basket of Apples surpass it at home. This improvement in the quality of the fruit must be very satisfactory to the Horticultural Society, for a few years ago there was but one kind of Apple at Bangalore, and that of the most crabbed description. It would be vain to attempt an enumeration of the different fruits that lay in tempting profusion upon the shelves, but I was disappointed in the Peaches and Strawberries, of which the public had hoped to see a goodlier show. This cannot be said of the Grapes, however, and one dwarf Vine, the property of Major Packle, the Secretary of the Society, was especially worthy of notice. Planted in an ordinary-sized flower pot, this handsome little tree was covered with large bunches of splendid ripe Grapes, but the most extraordinary part of its history was the fact that but one year ago it was taken as a cutting from the parent stem.

Among the flowers one could not help being struck with the beauty and good taste of Major Boddam's collection, and the same may be said of the cut flowers exhibited by Signor De Vecchi. The latter gentleman also exhibited some specimens of silkworms and silk, the last in softness and lustre being very remarkable. General Haines deservedly obtained a first prize for a lovely *Géant des Batailles* Rose, whose beauty, could it only be made to last long enough, might be justly said to be "a thing of joy for ever."

Among miscellaneous articles of exhibition, your correspondent remarked an American Grass, which he believes is indigenous to Rhode Island, exhibited by the Secretary as an excellent Grass for lawns. It is impossible to doubt the operation, as the specimen exhibited was very similar to the very richest "after grass" one sees in England in a first-class meadow field. The band of the 16th Lancers was in attendance, and discoursed most excellent music in the gardens outside, to the delight of a well-dressed crowd that sauntered about the lovely *parterres* of the Lal Bagh. Among the company present were Mr. Bowring, General Haines, Dr. Norman MacLeod, and Dr. Watson, and, in fact, the whole of Bangalore society, together with a

considerable portion of the outside world. Your correspondent has not heard how many individuals paid their rupees for tickets for admission, but he imagines there could not have been less than eight or nine hundred people present, of whom, owing to careful and wise arrangements on the part of the Committee, a very small portion were natives. It was long after dark before the last carriage reached home from a very pleasant entertainment.

The following extracts from the official Report in the supplement to the *Mysore Gazette*, dated Bangalore, 1st February, relate to this Show.

There was a marked improvement in the quantity, as well as quality of Canthflowers. Those exhibited by Nunjoondappa, and a single specimen by Nunjapah, were remarkably fine; whilst those displayed by the Lunatic Asylum and Colonel Clerk were also very good. In Carrots throughout there was a marked improvement this year, as likewise in Turnips and Red Cabbages. The Savoy and ordinary Cabbages and Potatoes also decidedly came up to the mark, as likewise some very fine Celery of Colonel Clerk's. The Celery of Mrs. Bowring was second best; but native production in Celery was too old and coarse. There was a falling-off in Asparagus and Vegetable Marrows, the Jurois missing as regards the latter the crinkled varieties of last year. Parsnips, Artichokes, Leeks and Sea-kale, which were hardly represented at the last Show, were very fairly represented this time; and there was the novelty of a dish of Brussels Sprouts.

The following flowers and plants were exhibited:—*Arum indicum*, *Achillea*, *Asters*, *Victoria*; *Achianenes gigantea*; *Antirrhinum*, seven varieties; *Camellia* *Ealsams*; *Bellis perennis* (Daisy), *Egonia discolor*, *grandiflora*, *dipetala*, *racemiflora*, *nigricans*, *fuchsoides*, *Rex*; *Calceolaria*, one shrubby kind; *Calliopsis nigra speciosa*, *Burridgei*, *Drummondii*, *tinctoria*; *Calliopsis involucreata*; *Camellia*, one specimen in bud; *Campaulia*, common kind; *Canna Warscewiczii*, *Chrysanthemum*, a dark red variety; *Cineraria maritima*, *Clusia elegans*, pink and white; *Cleome speciosa*; *Convolvulus mauritanicus*; *Caladium bicolor*, *Wightii*, *marmoratum*, *argyrites*, *picturatum*, *amabile*; *Crotou*; *Cuphea emensis*, *Deeringia celosoides*; *Dahlia* dwarf, one specimen; *Dianthus*, (Carnations) three varieties; *D. Heddewigi*, five varieties; *Krysinum arkaunum*; *Euphorbia fulgens*; *Ferns*, thirteen varieties; *Fuchsia*, seven varieties; *Zonal Pelargonium*, scarlet series, three varieties; pink, two varieties; cherry and white, one variety; *Cape Sweet-scented*, two varieties; *Heart-rose*, six varieties, *Heliopsis*, *Ivy*, *Larkspur*, common blue, pink, and variegated; *Lium coccineum*; *Lobelia cardinalis*, *L. speciosa*, three varieties; *Maurandya*, three colours; *Myosotis*, one common kind; *Nemophila maculata*, *Nolina lanceolata*, (*Eoothera Drummondii* nana, *Papaver* (Poppy), two colours; *Pentstemon*, three kinds; *Petunia*, one hybrid, *Dunnett's*; also rose-coloured and common white; *Phlox alba*, *P. Black Warrior*, *Empress Eugénie*, common; *Portulaca* single, three colours; *Roses*, nine distinct varieties; *Russelia*, one variety; *Salvia splendens*, *S. argentea*; *Sanvitalia*, single and double; *Tropaeolum Tom Thum*, Scarlet, golden yellow, *Trentham Rose*, common orange, common dark red; *Taxsonia ignea*, *Verbeena*, white, coral, purple, pink, scarlet, dark red; *Zinnia*, double.

Fruits consisted of Apples, Peaches, Strawberries, Raspberries, Oranges, Guavas, Pomegranates, Shadlocks, Plantains, Plums, and a Dwarf Vine in a pot just one year old with five bunches of ripe Grapes on it.

The vegetables were as follows:—Potatoes, Savoy, red and white, Cabbage, Brussels sprouts, Cauliflower, Carrots, Knol Khol, Beet, Lettuce, Endive, Artichokes, Jerusalem Artichokes, Celery, Onions, Vegetable Marrow, Cucumber, Parsnips, Radishes (long and Turnip), Kidney Beans, Asparagus, Windsor Beans, Peas, Tomatoes, collections of Pot Herbs—viz, Thyme, Parsley, Mint, Sage, &c., in bunches, Sweet Potatoes, fresh Capsicums, fresh Nepal Chillies, Pumpkins, Boudakai (*Hibiscus esculentus*), *Eriajals* (*Solanum melongena*), Turnips, and Yams.

Mr. Rivers, of Sawbridgeworth, had written to the Secretary of the Society, and the following is an extract from the letter:—

"From your height, 3000 feet above sea level, I am quite inclined to think you could cultivate Peaches, Nectarines, Plums, Pears, and Cherries, on low bush trees, for this reason, that they are more easily protected, when necessary, from a too powerful sun. Near Sydney the climate of which is far too hot for Gooseberries and Currants, they succeed in their culture by planting them in selected sites, and protecting them by a roof of strips of Eucalyptus bark, not too close so as to exclude all the sun and air: you might do it by a light calico awning. If you can grow 'excellent Apples' you need not feel any doubt about succeeding with other European fruits. Your courageous knife work is very interesting to read of: as far as I have learnt, it is the want of it that leads to so many failures in fruit culture in hot climates. The present gardener to the Pasha of Egypt, an Englishman, on his first arrival cut down all the Muscat Grape Vines which were in a very neglected state; the native gardeners were horrified; and would not believe their eyes when they saw them full of fine fruits a few months after they were 'ruined.' Your method of pot-making seems sound, but 13-inch pots would give you less trouble, as trees will grow in them for several years. I now endeavour to encourage the roots to come to the surface for warmth, by giving the trees three or four surface-dressings during the summer. It is well, as you suggest, to keep the roots from going too far down, not, as here, to prevent their striking down into too cold a medium, deep earth, but to prevent their becoming too large, in which case breaking them proves often too great a shock to the tree."

TRITELEIA UNIFLORA REMAINING DORMANT.

WHILST travelling in Italy during the winter of 1865-66 nothing pleased me more in the various gardens I visited than the numerous pots and patches of that lovely little flower *Triteleia uniflora*, and I made up my mind to grow it in my garden as soon as I got home.

Before I left Rome one of the gardeners at the Botanic Gardens gave me a large potful of bulbs. These I carefully planted as soon as I reached home in April. They came up very luxu-

riantly before Christmas, and though planted in a very exposed situation, and totally unprotected during that extremely severe winter, bloomed beautifully in May, 1867.

I was somewhat annoyed this spring to find no green leaves appearing from any of my patches of bulbs; so I dug down to the roots, and found every bulb in a dormant state, and showing no sign of growth. I should like to know whether any of your readers have noticed this peculiarity in *Triteleia uniflora*.—H. HARPER CREWE, *The Rectory, Drayton-Beauchamp, Tring*.

FLOWERS OF OTHER DAYS.

I WAS very much pleased to see the article with the above heading, in the Journal of March 12th, and I have no doubt with such resuscitating tendencies as that communication indicates, the flowers of the past will be the flowers of the future. If, after the manner of "H. HARPER CREWE," those who admire these old denizens of our old gardens, would bring before us what good things they possess, and inquire after the good things they are desirous to obtain, very much good might be done; and if a small space in the Journal were devoted to inquiries after these old favourites, and offering others in exchange, very many plants supposed to be lost would be brought into notice; and here goes for a start.

Any plant out of a collection of seven hundred will be given for a plant of *Ramondia pyrenaica*, or *Verbascum Myconi*, as it is sometimes called; also for *Dracecephalum grandiflorum*, and if "H. HARPER CREWE" will communicate with me, I can tell who has both *Baptisia australis* and *Narcissus triandrus* to spare.

Michauxia campanuloides is a fine and a rare plant. I introduced it a few years ago to the Liverpool Botanic Garden, where it was much thought of, but I should say it is more of a Passionflower-looking plant than a Lily. I do not grow it now, as I have no room for biennials.

The old Double White Cowslip has become extinct with me. The Double Yellow, or Hose-in-Hose, has been charming for some time. I have been gladdened with a pretty little plant from Lapland, which has been in flower for some weeks—*Caramine trifoliata*, a real gem, pure and white as its native snows.

Fumaria cava is also charming, and *Draba aizoon* is showing its golden tufts of bloom, and *Gentiana verna* is all but in flower; but I must rein-in my horse, or I know not where I shall gallop to.—THOS. WILLIAMS, *Path Lodge, Ormskirk*.

[You reined-in too soon, you might have kept on for another stage—that is, another sheet of paper.—EDS.]

NEPETA NEPETELLA.

I FIND, since I wrote to you about the *Nepeta*, that I have made a mistake in the specific name; it is *nepetella* not *nepetos*. I have also heard it called *Macrantha balsamea* and fragrans.

The first time I saw it bedded-out was at Hampton Court, in 1865, and on referring to some notes made at the time, I find it was labelled *Nepeta nepetella*. I thought it looked very pretty there, but from the appearance of the beds I think the old plants were allowed to remain in them, a course I would not advise, as I find it looks and does best when treated as an ordinary bedding plant.

It was bedded here last year as a third row from the front, Crystal Palace *Pelargonium* being the row in front, and *Trentham Calceolaria* immediately behind. There is another peculiarity in this plant which I have not seen in any other. When seen from a distance on a bright sunny day, it seems to throw up a blue light for 9 inches or a foot immediately above it, which gives it a singularly pleasing effect.

With regard to where it may be purchased, Messrs. Veitch had a stock of it two years since, but as it was not much in demand it may have shared the fate of some others of our old plants.

If treated as an ordinary bedding plant, I can vouch for its succeeding and looking well in lines in long borders. I do not think it looks quite so well in masses, but as I only saw it in masses at Hampton Court, and as probably the plants were old, it may look as well in masses as lines when treated differently. It has been used largely here for the last six years, and it has never failed to look and do well, whether the seasons were dry or wet.

I should like to say a word for our old herbaceous borders.

We have several here, and just now they look beautiful, while those parts of the garden devoted to bedding plants are bare. With the addition of a few bedding plants in May, the former may easily be made to look gay all summer, and where cut flowers are much in request they furnish a good supply without having to cut from other portions of the flower garden. They are also excellent trial grounds for new bedding plants, so that apart from their beauty at this time of year, they are very useful, and I think most gardeners who possess them would hardly like to do away with them altogether.—J. W. K.

[It varies in height according to the soil, from 1 to 4 feet. The following is its botanical description:—"Plant erect, pubescent, or clothed with hoary tomentum; leaves on short petioles, lanceolate, crenate, rounded or cordate at the base, clothed with hoary pubescence or tomentum on both surfaces; racemes many-flowered, nearly simple; bractæ scarcely longer than the pedicels; calyx tubular, incurved, with an oblique mouth; corolla twice as long as the calyx. Native of the South of Europe, especially on the mountains; as of Spain, Provence, Switzerland; Italy, from Piedmont and Liguria to Naples." There is no genus of plants called *Macrantha*. *Nepeta nepetella* passes into many varieties—varieties so strongly marked as to have been mistaken for species, among them are *Cataria nepetella*, *Nepeta amethystina*, *N. paniculata*, *N. lanceolata*, *N. graveolens*, and *N. arragonensis*.]

VALUE OF ORCHIDS.

MESSES. WALKER & ACKERLEY, auctioneers, Liverpool, sold on the 6th of March the remainder of Mr. Machen's choice collection. Of a *Dendrobium Falconeri*, said to be the finest plant in the country, Messrs. Veitch & Sons, of Chelsea, were the purchasers at the sum of 67 guineas. Two years ago Mr. Machen bought the plant, a very small one, for £14s. Since that time he grew it into the fine specimen sold as just mentioned, and which is thus described:—

"*Dendrobium Falconeri*, finest plant in this country of this scarce and lovely Orchid, with a leading shoot 5 feet 7 inches long, and having twenty-five side branches or plants, most of them having good roots; another leading shoot, 3 feet 8 inches long, has twenty-three branches, sixteen of which have roots and seven mature shoots, with bulbs; another shoot, 3 feet long, with three strong shoots, having roots, two strong branches, four mature branches, with bulbs, and sixteen side shoots or plants; another shoot, 3 feet long; ditto, 1 foot 9 inches; ditto, 1 foot; ditto, 2 feet 5 inches, with nine plants; ditto, 2 feet long, with eleven side shoots or plants."

NEW BOOK.

Cottage Gardening; Suggestions on Cultivation, Selection of Seeds, &c. London: Houlston & Wright.

This little book is written by an amateur contributor to our columns, and contains an enlargement of observations addressed by him to cottagers at the close of the Handsworth Floral and Horticultural Exhibitions, and for them and similar cultivators of small gardens it contains some useful suggestions.

WORK FOR THE WEEK.

KITCHEN GARDEN.

KEEP the Dutch hoe at work during this fine weather, not only to destroy weeds, but to prevent the ground becoming dry and cracked from rapid evaporation. Stir the soil amongst all advancing crops. Earth-up *Cabbages*, and water *Cauliflowers*, *Beans* and *Peas*, earth-up, and stake if necessary forward crops, and keep sowing successions of the Windsor *Beans*, and the *Marrows* and other large *Peas*. The *Victoria Marrow* is an excellent *Pea*, considerably earlier than, but not so good a bearer as *Knight's Tall Marrow*. The new sorts will be sufficiently tested this season. *Kidney Beans*, sow a few of the *Early Negro*, or *Fulmer's Forcing*, on a warm border, also a number in pots to be placed on a slight hotbed, and gradually hardened off and turned out when all danger from frost is over. *Radishes* and *Turnips*, sow on a warm border. If sown in alternate rows the *Radishes* will be pulled out of the way of the *Turnips*. To have the latter juicy and sweet sow every fortnight till August. The *Snowball* is an excellent early variety. Follow with the *White Dutch*, which is the most general favourite in the kitchen. Forward all your *Tomatoes*, *Capsi-*

cums, *Egg-plants*, *Ice-plants*, and all others in slight hotbeds, as they severally want more pot room and air. *Vegetable Marrows* and *Cucumbers* may now be sown for the summer crop out of doors. There is no want of long *Cucumbers* for early forcing, but really good sorts for pickling are very difficult to obtain. The frames in which early *Carrots*, *Radishes*, &c., were sown may now be removed for other purposes, and a few hoops placed over the beds ready to have mats thrown over them on cold nights. The hand-glasses over *Cauliflowers* may remain off while the nights are mild.

FRUIT GARDEN.

If you have any doubts about the names of recently planted *Peach* and *Nectarine* trees and any of the old ones, mark them before they are out of blossom—that is, mark if the flowers are small or large, by cutting a notch or number on a stick for one kind of flower, and another number for the other kind; two numbers will do for the whole. This is the first regular step towards ascertaining the name. The glands and serratures, if any, on the leaves, will be the next step by-and-by, and you will then have a chance of making out the name by consulting Dr. Hogg's "*Fruit Manual*." As yet there is a fair promise that *Peaches* and *Apricots* will set well. Continue to disbud them gradually, thinning-out buds from the strongest shoots first. In cold exposed situations plantations of *Strawberries* made now from plants pricked out thinly last autumn in a sheltered situation, will succeed better if transplanted with balls than if the plantation had been made in the autumn. The ground should be previously well trenched and manured; except for new kinds there is no method of making fresh plantations comparable to that of turning out plants forced in pots.

FLOWER GARDEN.

Newly planted trees and shrubs will require strict attention in regard to water, as they already indicate the want of it. It is better to give them a thorough soaking at once than to give them a little water frequently repeated; and after the surface of the ground is dry fork or hoe it over, and then mulch with short grass to prevent the evaporation of moisture. The same remarks apply to newly planted annuals, which must be shaded as well as watered. Turf which has been recently laid down requires great attention. It will be a good plan, after giving it a thorough soaking of water, to dress it over with old tan or leaf mould, and then shade it by covering the ground with any refuse branches that may be lying about. Put in a successional crop of *Sweet Peas* or any other annuals that were sown early in the year. Sow *Ten-week Stocks* for transplanting. The finer kinds of *Gladiolus* which have been brought forward in pots may now be planted out, giving a deep, rich, and well-drained soil; but it will be as well to protect them by an inverted pot at night until all danger of frost is over. Attend to covering half-hardy shrubs and trees.

GREENHOUSE AND CONSERVATORY.

In this central place of attraction, the conservatory, there will be some difficulty to contend with for a few weeks. Forced *Roses*, *Lilacs*, *Azaleas*, &c., will be going out of bloom, and must be removed to give place to a fresh lot; but where can they be sheltered till they become hardened enough to bear the open air? Every one must answer this question according to his means. This is the best time to cross-fertilise the finer varieties of *Rhododendrons* and *Azaleas* which have been forced, as none of the more common sorts can now interfere with the experiment. Orange trees require particular attention when they are making their young wood. Stop luxuriant shoots at the fourth or fifth joint; no one part of the head should be allowed to grow stronger than the rest. Young trees may require some of the stronger branches to be tied down for a time, this will strengthen the others. Climbers for this house should now be planted if additions are to be made to them this season, and see that the young growths of the old ones do not become entangled from want of training. In the greenhouse plants will require all the air that can be given them, and they will be very liable to become very dry on that account. Water them late in the afternoon, and damp the paths and all empty spaces freely. Give them, besides, a gentle syringing three or four times a-week when the weather is fine. These plants require constant attention now to stopping and regulating their growth.

STOVE.

No opportunity should now be lost to pot all plants that require it. Plants that have been growing for some weeks, particularly young ones, will now require to be stopped more or less in order to make them bushy. Never make use of a

stick to give form to a plant that can be managed by pinning and stopping. Many plants will require slight shading in the middle of the day, but this should be removed early. After shifting the greater part of the plants keep the house closer for a week or two to encourage the roots to strike freely into the fresh soil; keep up a moist atmosphere also, and give less water to the roots, as the fresh soil after the first watering will be moist enough for some time. *Rondeletia speciosa* is an excellent plant to flower in the conservatory for seven or eight months in summer. It is rather difficult to grow it so as to form a good specimen, and more so to propagate it by cuttings; but if there are young shoots low enough, layer them in the pot, and they will root freely in three weeks.

PROPAGATING PIT.

After the supply for the flower beds is propagated and a little forwarded, put in for a reserve a quantity of cuttings of such plants as flower late in the autumn to take the place of those which go off in September. All the *Heliotropes* for forcing next winter should be propagated now, and kept cramped in small pots through the summer. Any other plants that are found difficult to preserve through the winter should now be propagated while the pit is at work, and if kept stunted in small pots during summer they will become so hardened and stocky as to keep with ease through the winter. As these pits are the last places for propagation, and as this work does not admit of large portions of air being given, they must be regularly shaded in hot dry weather; thin bunting or calico should be used for this purpose, mats darken too much.

PITS AND FRAMES.

Proceed with potting-off all plants for bedding-out; those which have become established and hardened may be removed to temporary pits, and covered at night with mats.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Dwarf Kidney Beans.—Not having a pit at liberty, turned out a number of strong plants of Kidney Beans from 5-inch pots into 10-inch pots, and gave them the benefit of a pit for a time, in order that they may succeed those now producing. After the present time this useful vegetable will do very well in a frame with a mild bottom heat. No vegetable is more partial to a dry heat in winter and early spring, provided the dryness in the atmosphere is counteracted by syringing and evaporation from saucers, &c. The plants will produce more plentifully in a roomy house than in a dung pit even now; but there is always a risk in taking them into houses. We have grown them for years in vineries, and never had a thrips on them; but we have also had them so infested that we were glad to remove them carefully, so as to leave as few of the insects as possible. Clear soot water for syringing is good for keeping red spider and thrips away, and we have more faith in preventives than in cures. Many a pound goes for fumigating plants, when it would be the best economy to clear all out and save the trouble. When smoking is resorted to there should be no waiting to see a second or third insect, one should be sufficient. Smoking after the leaves are incrustated with insects is worse than labour lost. It is rarely that such plants do good afterwards. Smoking will kill thrips; but as it always appears on the older leaves, if these be removed carefully in good time, and the syringe freely used, the thrips will generally be kept under. When we grew very early Cucumbers we examined the leaves carefully, and if a solitary thrips was discovered we pounced on it with the point of a wet finger. This could be done only when the plants were grown on a trellis, and in such a place that one could walk or pass underneath them. Quickly as they jump, the eye and the finger of a young lad can be more nimble still, and they cannot jump when encased in moisture. Plants can be fit for little else but the furnace when thrips is seen on the upper surface of the leaves.

Cucumbers.—Those in frames and in a pit heated by hot water are running a very equal race. Those in the frame have required much less attention. In low pits, heated by hot water, the plants require more watching in changeable weather. It is advisable to use shading as little as possible, and in dull days to moderate the heat given, instead of affording too much air; but after two or three days, when no sun appears, the plants are apt to suffer when the sun comes out bright all at once. Sprinkling the floors and walls with water will often then neutralise the change, and if the glass is good the plants may even be sprinkled, especially on the lower side of the

leaves. In such bright sun, after dull weather, it is of importance to have the heating medium tolerably cool before the sun strikes strongly on the glass. In large Cucumber houses this additional care is less needed, as, from the greater body of air to be heated, sudden changes are less felt. When Cucumbers are wanted regularly in winter, there can be no comparison between steep-roofed houses and flat pits, and the same may be said of Melons in summer, for though five Melons are grown in frames and flat pits, we have no hesitation in saying that Melons grown on a trellis and with plenty of sun will, size for size, be generally heavier than those grown and trained on a bed.

FRUIT GARDEN.

Strawberries.—There was only one little operation out of the routine alluded to in previous weeks' notices, and it may be interesting to mention it for the benefit of beginners. As a general rule with us this season, Strawberries have been longer in setting than usual. There was a good deal of dull weather, but there was also sun enough now and then to complete the fertilising process. Even in our Peach house, with the roof at an angle of 45°, and shelves tolerably close to the glass, the best position we have ever had for free setting, the pots continued longer in full bloom than usual before the berries began to swell. We used to grow many on solitary shelves in pits, as what may be termed stolen crops; but these positions always did better for swelling-off the fruit than for setting them well, owing to two causes—viz., the comparative flatness of the roof, and the greater moisture in the pits, proceeding from the other plants grown in them. We considered we would escape this latter drawback by appropriating part of a pit to Strawberries solely, and it is to a simple fact connected with it that we wish to allude. The bed in the pit was chiefly rather dry soil, and we raised a temporary stage with boards from 20 to 24 inches above this floor, the stage sloping the same as the glass, so that each row should have all the light possible. No plants could have looked better, or shown bloom more strongly, but both foliage and flower trusses became rather longer than usual and almost touched the glass. The consequence was, partly from the moisture in the pit, partly from the glass condensing the vapour, even with the help of a little air on at night, that the foliage and flowers were often so wet in the morning that one might have washed his hands amongst them, and on a dull day they would scarcely be dry before night. We tried covering the glass at night to arrest the radiation of heat from the glass, and thus lessen its powers as a condenser of watery vapour; but even this was not quite effectual, the blooms were still too wet to allow of the process of fertilisation being thoroughly accomplished. We then took the plants and stage out, lowered the latter 6 inches, and used a thicker covering at night, and since then the plants were dry in the morning with just a few dewdrops here and there on the points of the leaves, and the setting and swelling proceeded rapidly. Now, this simple fact shows—first, that in confined pits it is possible to have Strawberry plants too near the glass; and, secondly, that it is very easy, even with hot-water piping, to have too much atmospheric moisture. We could have dissipated the latter by giving more air and more heat, but we could not well give more heat under the circumstances. The lowering of the plants and the covering of the glass in cold nights proved an effectual remedy. The points of the foliage were not so much cooled when farther removed from the clear radiating body of glass, and the condensation of moisture was next to entirely neutralised by the covering of the glass. Every leaf hanging with dewdrops in the morning told the tale, that the points of these leaves became colder than the surrounding air before they could condense the vapour contained in it. When Strawberries are grown in houses of even moderate size, it is very rarely that they will suffer from excess of condensed moisture.

ORNAMENTAL DEPARTMENT.

For general work, see previous weeks' notices. We will to-day confine ourselves to a few words on *hardening-off bedding plants*, merely premising that we have had much to do still with propagating, sowing, and pricking-off seedlings. Many small things, as *Lobelias*, we prick-out in little bunches until they become larger, as it is advisable not to have them long in their seed pots. We mentioned last week having our earth and turf pits made ready, forking them over, &c. The sharp frost of several mornings did good to the soil, but prevented us using it until it should be rather well warmed. Before this is printed, if the weather be at all favourable, we shall have a great many plants under protection out of doors, and thus have something like moving room in our houses. *Calceolarias*

we shall plant separately in these preparatory beds, raising them out of the beds in which they were inserted as cuttings last October. Verbenas we often plant separately, and at other times we turn out small cutting pots. A considerable amount of moving is thus incurred, but it cannot be helped so long as every glass structure has to serve so many purposes. Besides saving pots (as the same small pots will be filled and emptied a number of times the same spring) we believe that on the whole the temporary planting-out saves labour, and that the plants do better than when left standing under some kind of protection. Thus, in the case of *Calceolarias*, after planting-out now, they rarely are ever watered again before they are taken to the beds.

As we know that numbers of our readers are now at a loss for room, we shall shortly tell how we manage, and not to be intricate will take *Scarlet Pelargoniums*. These in general are struck and kept in small wooden boxes, merely nailed together, and about 3½ inches deep. Some of these we manage to put into 60-sized pots, and, when established, we turn them back into the boxes, so that each will come out again with a ball, and these are protected with mats, branches, &c. Lots more, the pots getting full of roots, we have turned out into earth pits. The plants are well watered before they are turned out of the pots. They are then set with their balls along a little trench, the balls but a short distance apart, and a little rather rough rich soil, shaken among them from the spade, this soil consisting chiefly of leaf mould, old mushroom dung, and riddlings from beneath the potting bench. This is firmed round the balls with the hand, and then the natural soil placed, and another trench cut out, just giving the plants room enough to grow slowly for six weeks or so to come. We gain by not watering the soil, as that is already moist enough, and if the tops of the plants can be kept dry, they will root very quickly in the new material, and at lifting time the roots will be protruding into it, and the only care is not to let any of the roots drop off when lifting. Between this mode and turning out from hard balls in pots there is no comparison as to the plants doing well. Of course it can only be largely practised when the flower beds are at no great distance. These plants will rarely show their moving, when transplanted. The last potted must in general go into the beds from the pots. A great proportion of our plants, however, are never placed in a pot. Great numbers were taken from these cutting boxes and planted-out separately the same as the above, only the roots of each are kept pretty close at home, and the fresh rough soil placed along the trench. These will ultimately do quite as well as those that were potted, but in hot weather, after final planting, they will be a little distressed with bright sun for a few days, so that they are better suited for places that do not come prominently into view immediately after planting. Except for showing this little distress at first, this simple plan answers so well as to leave nothing to be desired. We may also mention that when we have three or four neat little plants in a 60-sized pot, and there is scarcely time to let them become established separately, we often turn out the ball as above with fresh material round it, and at planting time, from the lot of fresh fibres, we can easily break it into three or four good pieces, and each will be much better than if it stood with its neighbours in the pot.

Now, as to *protection*, we use everything—evergreen branches, straw hurdles, hurdles with green branches drawn through them, mats stretched tight, &c., but of all things we prefer old sashes if they can be had, as they can be duffed if necessary, and next to these unbleached calico. We, on the whole, prefer the latter when we can obtain it, as it gives so little trouble, keeps the plants rather dry when it is strained tight, lets enough of light through for good sturdy growth, and keeps enough of the fierce rays of the sun out to make anything like shading unnecessary. In very severe weather we have placed a little straw or evergreen boughs over it at night. It is best when 2 yards wide, and in proportion to the length of the earth pit, handy lengths may be from 6 to 10 or more yards, each end being fastened to a pole for rolling it on, and for drawing it tight. Cross pieces of wood, as stout flower stakes, are laid across the pit some 4 feet apart, to prevent the cloth bagging, and besides the poles at the ends, a string is fastened on each side at every 4 feet or so, which when fastened to a pin keeps the cloth tight, and thus heavy rains are mostly thrown off. We have had plants thriving beautifully under such protection, and scarcely moved for a month or six weeks, except holding it up two or three times in very bright days to syringe

the plants. Often the plants were never watered from the time they were turned into the bed until they were taken to the flower garden. Nothing can be more suitable for the enthusiastic amateur. If confined solely to this spring work, and put away dry, the same cloth will last many years. We prefer it unbleached, not too strong, and without glazing or waterproofing.—R. F.

COVENT GARDEN MARKET.—APRIL 1.

A slight improvement is observable here, and, notwithstanding the heavy supply of some articles, prices have been maintained. Among foreign produce we have again had some fine specimens of Cayenne Pine from St. Michael's. Good Potatoes also meet with a ready sale at a slight advance upon former quotations.

TRADE CATALOGUES RECEIVED.

Chivas & Weaver, Chester.—*Price List of Agricultural Seeds.*
 Ambroise Verschaffelt, Rue du Chaume, 50, Ghent, Belgium.
 —*Prix-Courant pour Printemps et Eté, 1868.*

TO CORRESPONDENTS.

.. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

Books (K. J.).—Hooker and Arnott's "British Flora," or Bentham's "Handbook of the British Flora." Each is arranged on the natural system. (*Man of Kent*).—The book you allude to is not the one we promised in the spring. It will be duly announced when ready in the Journal. (C. P. O.).—The price is 3s. 6d. You can have the book by sending your address and enclosing 3s. 6d. in postage stamps to the author—Mr. Grieve, Rev. E. K. Benyon's, Culford Hall, Bury St. Edmunds.

FOWLER'S GARDENERS' INSECTICIDE (A. A. S.).—Fowler's Gardeners' Insecticide may be had through any seedsman, or from Messrs. Fowler, North Street, Brighton.

PLANTING CHRISTMAS ROSE (*Idem*).—The best time to plant it is from July to October. It likes a moderately light soil enriched with leaf mould, and does best in well-drained ground, though it will thrive almost everywhere. It may be had of any florist or nurseryman, and through most seedsmen.

CAMELLIAS (*Et red*).—We do not wonder at your perplexity. The following selection is extracted from "The Gardener's Almanack" of this year. You can have it free by post from our office for thirteen postage stamps, and you will find in it similar selections of the principal flowers. Alba plena (Casoretti), Alba plena, both white; Archduchess Augusta, crimson; Anlica, blue-b, striped; Beauli, dark red; Belle Jeannette, red, white stripes; Caryophyllides, striped; Countess of Derby, white, rosy stripe; Countess of Orkney, white, red stripes; Duchess of Buccleuch, pink; Eximia, bright red; Henri Pavre, light pink; Jardi d'Ilver, rose; La Reine, flesh colour; Lavinia Magde, striped; Mathotiana, crimson; Monarch, rosy scarlet; Mrs. Abby Wilder, creamy white; Princess Bacchiotti, dark crimson; Saccosina nova, rose; Storyii, striped; Valtevarado, deep pink.

CURRIERS' REFUSE (*Idem*).—If merely scraps of leather, it might be applied to your Vine border on the same principle that woollen rags are

applied to Hops. They decompose slowly, and do not induce over-luxuriance.

DIGGING UP POTATOES (*Lili*).—So soon as the Potatoes have attained their full size, although the stems and most of the leaves remain green, there is no loss either in weight or quality. You must buy plants of the Primulas you mention, and ripen seeds for yourself.

MR. EDWARD TUCKER (*E. R.*).—We have few farther particulars of him. He was in his fifty-ninth year, and died at his house in Cecil Square, Margate. He was born at Stodmarsh, in the Isle of Thanet.

INSECTS ON PEACH TREES (*J. B. L.*).—There were no insects in your letter.

PEAS (*R. Nash*).—The earliness has been fully tested by the Fruit Committee of the Royal Horticultural Society. We do not know any one who gives cuttings.

APPLYING GUANO TO ROSES (*C. F.*).—"March is not a good month for applying ammoniacal manures. If guano be put on now it must be raked in. It is difficult to say what quantity of guano each Rose would require. The quantity depends on the quality and condition of the ground. Moreover, some Roses, even in the same family, require different quantities. I advise you to put one handful of Peruvian guano into an ordinary-sized watering pot (the size of a stable bucket), and after stirring well to pour the liquid over the surface as far as the roots may be supposed to reach. Guano in this form may be advantageously applied after the first series of flowers is over. Liquid manure much reduced with water is also a good application."—*W. F. RADCLIFFE.*

HEATING A SMALL HOUSE (*Joseph Mark*).—If you can employ gas have one of Shrewsbury's heating apparatuses. If you write to him—"Mr Shrewsbury, Ironmonger, Lower Norwood, Surrey," stating the size of your house, he would tell you what would suit you. Hay's stove cannot now be obtained.

HEATING A SMALL SPAN-ROOFED CUCUMBER HOUSE (*Willie*).—In such a house, 20 feet by 8, you will require two 4-inch pipes for bottom heat, and three pipes, or 60 feet, for top heat, and troughs on the latter to be used when moisture in the atmosphere is wanted. You say nothing as to how your house is to be arranged, whether all the width is to be a bed, or whether you mean to have a path in it. In either case the mode described to a correspondent lately would meet your case. If you give us more particulars we may advise more definitely.

PRUNING ORCHARD HOUSE TREES—THINNING FRUIT BUDS OF PEACH TREES (*H. M.*).—As your trees were pruned before you received them, and prepared for fruiting, we should think that they want no pruning-back now, as it would much weaken them. In thinning fruit buds of Peach trees when too numerous, it is well to leave the wood buds to encourage growth. These can be thinned when grown an inch or more, doing that gradually, and leaving plenty for next year's crop.

VINES MILDEWED (*G. E.*).—We have no doubt that the tank in the centre of the house, merely covered with boards, having 2-inch spaces between them, is the cause of the mildew. Much vapour would rise from the tank when the house was warm, and a heavy rain would also greatly cool the house. We presume that the eight openings for ventilation are at the top of the house, and that you have other ventilation at the sides, otherwise we should judge there was not enough of ventilation. We should certainly cover the tank closely by putting the boards close together, and even then would be disposed to cover with a couple of inches of concrete, and place some fine gravel on the top, and fixed in the concrete, for a path.

LAWN MOWER KNIVES NOT CUTTING (*Rector*).—If the knives of a lawn mower are chipped with stones, the best plan to adopt is to have the knives replaced by the maker, as they could not be ground to take out the chipped parts well. When the knives merely get blunt from use put a little emery dust on them and turn them against the plate in the reverse way.

GROWING MELONS AND CUCUMBERS IN A PIT WITH A FLUE-HEATED CHAMBER (*Idem*).—In your pit with a chamber heated by a flue, the fire in the flue will be of great use for Cucumbers and Melons until the end of June, and even after that in cold dull weather for keeping the plants healthy. There should also be openings from the chamber to let the heat into the atmosphere of the pit in cold dull weather. You had better grow Cucumbers at one end, and Melons at the other. A good average heat would be from 65 to 68 or 70 at night, allowing a good rise from sunshine.

ERECTING AND HEATING PITS (*J. D.*).—There will be no difficulty in your proposed arrangement as to the pits, heating, &c., and the position as to the back wall is entirely one of convenience and of outlay. By using the stone wall for the back of the pits you save the expense of building a wall; but you must do all the necessary work from the front of the pit, either by tilting the lights up or taking them off; and for many purposes this can be easily done. By building a fresh wall for the back of the pits, and leaving a pathway between that and the present stone wall, you can examine the inside of the pits from back and front, and do most of the work by sliding the sashes up and down. Were we studying economy and convenience we would make a low house against the stone wall, so that we could walk inside, and have a fixed roof.

KEEPING A STREAM CLEAR (*Neptune*).—The pebbling of the bottom of the stream, or concreting it, and then pebbling it, would help to keep the water clean, and after the lime had lost its acidity would not harm the fish. If this cannot be carried against the gravelling or pebbling the bottom must then be resorted to. Besides the fish, a few water fowl would help to clear the brick walls of the green slime. If that is not effectual the walls might be cemented; but then the fish would have to be removed. We have considerable trust in the pebbles, the fish, fowls, and lime. We have known of several cases where cleaning out the bottom of a stream that did not have a hard bottom has been followed by similar results, as many impurities previously buried for years obtained more free access to the water. The removing of the mud, in fact, made the water turbid for a year or two afterwards. As respects the Willow slips, you had better strike them in common or damp ground, and when established plant in your rockwork mound, so that the bulk of the roots shall be in water. The roots will reach the water by themselves. Nothing strikes more readily than the Willow.

GROWING MUSCAT AND HAMBURGH GRAPES IN THE SAME HOUSE (*W. S., a Constant Reader*).—You may grow Muscat and Hamburgh Grapes

in the same house very well by planting the Muscat Vines at the warmest end where the heating apparatus ends. Had we two distinct houses, however, to plant in, we would much prefer to have a house for each. We do not know ten distinct Muscats; but you can, if variety is a great object, grow Frontignans in the Muscat house. The Muscats we recommend are Muscat of Alexandria, Bowood Muscat, Canon Hall Muscat, and one plant of Black Muscat of Alexandria. For Hamburghs—the common Black Hamburgh, Victoria Hamburgh, Dutch Hamburgh, and Champion Hamburgh. We would not retransplant the Camellias until growth had ceased and the buds were formed at the points of the shoots.

CERASTIUM TOMENTOSUM AND GNAPHALIUM LANATUM CUTTINGS (*Man of Kent*).—When rooted and hardened-off the cuttings may be pricked-off in a sheltered border, moving them with a ball to their final place in the flower beds in May; or, if the plants are now well hardened you may at once plant them out where they are to remain. *Cerastium tomentosum* is perfectly hardy, but is somewhat liable to die off in winter on heavy soil. *Gnaphalium lanatum* is also hardy, but requires gravelly or well-drained light soil, otherwise it does not survive the winter.

TREATMENT OF VIOLA CORNETA AND V. LUTEA SEEDLINGS (*Idem*).—When sufficiently large to handle they should be pricked-off in pans of light soil, enriched by the addition of one-third leaf mould or very rotten manure. Prick them off about 1 inch apart, keep them moderately moist until established, then water copiously, and keep them near the glass in a cold pit or frame, giving them an abundance of air, and plant out in May. If you write to Mr. Richards, Assistant Secretary, Royal Horticultural Society, South Kensington, he will send you full particulars.

VERBENA VESUVIENSIS (*Idem*).—The flower is orange scarlet, with crimson centre and white eye; fine truss and good habit.

RED SPIDER IN SOIL OF VINE POT (*J. J. H.*).—You may free your soil of the red spider by watering it with guano water, 1 oz. being dissolved in a gallon of rain water, and applied at every alternate watering; or you may place a week of soot in a tub and pour over it thirty gallons of water, stirring well up, and water the plant with it. Both liquids will benefit the Vine. The surface of the soil in the pot may be made quite black with soot. It will act as a manure. Soot is the best destroyer of red spider known.

PROPAGATING CALLISTEMON LANCEOLATUS (*A Sussex Ficar*).—Cuttings should be taken of the points of the shoots when the terminal bud is formed, and before the wood has become hard; but it is necessary that the wood be rather firm, or in the condition known to gardeners as half ripe. The cuttings may be from 3 to 4 inches in length, and should be cut across below a leaf, removing the leaf, and from one-half or two-thirds the length of the cutting upwards the leaves should all be removed. Pots 4 inches in diameter will be sufficiently large for the cuttings if these are not large, or 6-inch pots may be used if the cuttings are strong. The pots should be half filled with crocks, and over these should be placed a thin layer of moss or turfy peat, filling to within an inch of the rim of the pot with a compost of good fibrous sandy peat one-third, and two-thirds silver sand, and the remainder of the space with silver sand. Each pot thus prepared should be placed inside of a pot a size larger, or large enough to admit the cutting pot, and when raised so that both rims are on the same level, there will be an interval between the two pots. The cutting pot is to be raised to the same level as the outer pot by placing it upon small crocks. Half fill the interval between the two with small crocks, place a layer of moss above these, and bring level to the rim of the other pot with silver sand. The pot should then be watered thoroughly with rain water, and be allowed to drain well before the cuttings are inserted. They should be put in round the sides of the pot, and close to but not touching each other. A gentle watering should then be given, and after the cuttings have been allowed to dry plunge the pots in a mild and sweet bath of from 65° to 70°. Cover them with a bell-glass resting on the sand between the pots. Afford shade from bright sun, and attend to watering, so as to secure uniform moisture, for if the cuttings ever suffer from the want of it they never succeed. The bell-glass should be taken off every day and wiped dry, returning or replacing it immediately. When they are rooted the bell-glass should be gradually taken off, so as to harden them off before being potted. If you have tried this plan and failed, take cuttings of the young shoots when they are 3 inches long, taking them off close to the old wood, and with a small heel of the older wood; make it smooth with a sharp knife, remove the lower leaves, insert the cuttings in pots prepared as above, and follow the same mode of treatment.

GRAFTING APPLE TREES (*C. P. O.*).—You do not say how thick the stem of your seedling Apple is, nor how many branches it has. If it is not thicker than your thumb we would cut it down to within 6 inches of the ground, and there graft it; but if the stem is as thick as your wrist, and the branches forming the head as thick as a finger, we would cut all but three away. Cut them in to within 6 inches of the stem, and in each insert a graft. The best mode of grafting will be whip grafting, whether you graft upon the stem or side branches. If the side branches are thick, crown-graft, putting two grafts in each branch. You will find full particulars as to grafting in the "Science and Practice of Gardening," which you can have free by post from our office for 2s. 18d.

FERTILISING PRIMULA FLOWERS (*Primula*).—The process is to take the pollen from the anthers and apply it to the stigmas of the flowers. A camel's-hair pencil is best for the purpose. The pollen should be taken from the largest and best-coloured flowers, and applied to the stigmas of those having large blooms, good in colour and form. The operation should be performed in the early part of a fine day, and a few days after the flowers are fully expanded.

VINE EATEN BY RATS (*Constant Reader*).—The Vine rather more than half eaten through by rats will not only live but produce good crops. We would not cut it down. If a shoot come from below the eaten part allow it to grow, giving it every encouragement, and when it has reached the rafter train it up by the side of the older rod, allowing it to make as much growth as it will this season. The old cane after fruiting may be cut down to the young cane, which will, of course, be substituted for it, and you will not lose the crop. If no shoot arise from the stem below the eaten part, be satisfied with the Vine as it is.

NEPETA NEPETELLA FROM SEED (*Celia*).—It may be raised from seed, but plants so raised do not flower well the first year; for them to do so the seed should be sown early and the plants forwarded in heat. Plants from cuttings are better, being more free-flowering, and more compact in habit. It is a good, old, free-flowering plant, and continues a long time

in bloom, being superior to *Viola cornuta* in this respect; but is inferior to the *Lobelia speciosa*, and not nearly so effective in colour.

MYOSOTIS AZORICA (Idem).—Plants from seed sown now will not flower until autumn, and even then very sparingly if at all; but they will by that time be good plants for planting out, and will make a fine display early the following summer. This *Myosotis* is not suitable for summer bedding. We have it for flowering early in summer or late in spring, and it is very fine in May, but it will not endure sun or drought.

OLD CHERRY TREES DECAYING (J. D. Ireland).—Your proposed covering of the excrescences on the branches and stem with clay will not prevent further decay of the trees. It would do quite as much harm as good. The application of a good dressing of manure would be of greater service to the trees by invigorating the roots, than anything applied to the branches. The evil is in the roots, and your best course will be to remove the trees when they cease to be productive.

STOPPING VINE LATERALS (J. Subscriber).—We would not stop the laterals as soon as they appear, but allow those at the base to grow until they had made six leaves, then take out their points. We would thus treat all laterals that came on the stem or cane up to 3 feet; all laterals in the next foot of height we would allow to grow until they had made five leaves and then stop them. From 4 feet up to 5 feet we would stop at the fourth leaf; between 5 feet and 6 feet at the third leaf; and between 6 feet and 7 feet at the second leaf. All over 7 feet we should keep closely pinched, in the first instance at the first leaf, and stop all sub-laterals at the first joint, and this repeatedly as they were produced. We thus have as good eyes and as strong wood at the base as at the upper end of the cane.

CUTTING GRASS (E. J.).—By cutting the grass well into the bottom we intended it to be understood that grass at the first cutting should be cut very close to the ground.

SHADING A GREENHOUSE (Idem).—For flowering plants shade, but for growing plants shading will not be required except when they are fresh potted, or are plants requiring shade—such as Ferns and Orchids. We do not recommend you to colour the glass so as to render it opaque, and we would advise a shade of tiffany. It will be required quite as much for the roof as the front of the house, and would be best outside, attached to a roller, and run up and down as required. The plants cannot be kept too near the glass if they do not touch it.

PROPAGATING POLYANTHUS, PRIMROSES, AND DAISIES (Idem).—The best time to propagate these plants is when the bloom is over. Plant the divisions on an east border or other situation shaded from the midday sun. They should be shaded and well watered until established.

TREATMENT OF PERILLA, ASTER, STOCK, AND PHLOX SEEDLINGS (Idem).—They may be kept in the greenhouse, after they are pricked off, until bedding-out time, but they should be well hardened-off by affording them an abundance of air, and would be all the better of fall exposure in May, placing them in a sheltered situation, and affording protection from frost, should it occur. If the plants are not further from the glass than 12 inches, they will do well, and if but 6 inches they could not be better placed. Indeed, they cannot be placed too near the glass.

TREATMENT OF BULBS AFTER FLOWERING (H. B.).—If the Hyacinths and Tulips have been forced early there is no mode of treatment by which they can be made to flower well after the first year; but if merely brought on in a gentle heat they will flower well for years in the open ground, but are not equal to imported bulbs. When the flowering is past the bulbs should not be placed under the stage, or be planted in the open ground, but ought to have a light airy situation near the glass in a cool house or cold frame, giving them copious supplies of water until the foliage ceases growth, when watering should be discontinued gradually, and entirely left off by the time the foliage turns yellow. When the leaves are completely yellow the plants should be turned out of the pots, and if their roots are all gone shake away the soil, and place the bulbs on shelves in a cool airy shed to dry. When thoroughly dried remove the old roots, dead flower stems, and leaves, which, being mature, will part freely from the bulbs. Having removed the offsets from the bulbs, place them in layers in a box in dry silver sand, and keep them in a cool dry place until October, when they may be planted in the beds or borders of the garden. The Hyacinths should be planted with the crown of the bulbs from 1½ to 2 inches below the surface, and the Tulips about an inch. A well-drained light rich soil is most suitable, but any well-drained and not very adhesive soil will grow them well. In November or early in December before severe weather, give a mulching of about 1 inch of half-rotten leaves, and this is all the attention our bulbs receive, and we always have a fine bloom in spring or early in summer. When the foliage decays we take up the bulbs, remove the offsets, and replant at once, after giving the ground a dressing 1 or 2 inches thick of equal parts of rotten cowdung and leaf mould. This should be well mixed with the soil, which is trenched to a depth of not less than 15 inches, but the deeper the better. We do not take the bulbs up oftener than every second year, and then we are obliged to do so on account of the offsets. Our soil is light loam resting on gravel. It is never wet. There is no necessity to take the bulbs up and dry them, as the summer plants can be planted between the lines of bulbs. In heavy soils, however, we would take the bulbs up annually, and store them as already described, replanting in autumn

when the summer plants are cleared off, and after the ground has been well prepared for the reception of the bulbs, without which it is needless to plant them. As to the offsets, we plant them in beds in lines 6 inches apart, and 3 inches apart in the line, drawing a shallow drill, and putting them in the same manner as Shallots, then covering with about an inch of fine soil. We do not keep the offsets an hour longer out of the ground than can be helped. A mulching of half-rotten leaves 1½ spread over the offset beds in autumn before severe weather sets in, and the ground between the lines is lightly stirred in spring. After two seasons' growth we have fine flowering bulbs for planting in beds and borders. We have often had Hyacinth bulbs home-grown weighing 4 and 6 ozs., and a few even 8 ozs. weight.

PROPAGATING PANSIES (Flora).—We would advise your procuring a few good plants of the kinds you require, and at once planting them out 1 foot apart. Layer the shoots by pegging them down, and by these means you will obtain strong plants, especially if your soil is light and you place fresh cow dung around the base of each plant. You will have numerous cuttings by July, during which month you may take off all the points of the growing shoots, and especially those coming from the collar of the plant. Three inches will be sufficiently long. The cuttings should be cut below a joint, and the leaves removed from all but the upper third of the cuttings. They should be inserted in a compost of equal parts of loam, leaf mould, and silver or sharp sand. A rather shady situation should be chosen, and the cuttings, after insertion 1½ inch apart every way, may have a good watering, and should be covered with a hand-glass or frame, the lights being kept close and shaded from bright sun. No pains should be spared in attending to watering and shading, for if these be neglected, and the cuttings flag, their rooting will be retarded, if they do not fail altogether. A little air may be given in the early part of the day to dry up any accumulation of damp, and when the cuttings become rooted, air should by degrees be freely admitted; when well rooted they may be fully exposed.

PERILLA NANKINENSIS for a LOW EDGING (Idem).—The best way to form a neat edging of Perilla is to plant a double line of it for a 2-foot edging, placing the plants 1 foot apart every way, and pegging them down after they have become well established. For pegging the shoots down we employ bamboo, cut into 4-inch lengths, avoiding the joints. We split the lengths into small pieces about the thickness of match wood, and throw them into water to soak, which makes them very pliable. We peg down the shoots with these bent between the finger and thumb, and thrust into the ground. When bent they look like hair pins, and are the cheapest and best pegs we ever saw or used. We continue the pegging until the plants meet, and we then pinch back the small shoots, and all shoots are kept pinched to one joint, or two at the most. The first stopping takes place when the shoots are about 6 inches long and after pegging is discontinued. If you require an edging of 1-foot width one row of plants will be sufficient, putting the plants in from 9 inches to a foot apart.

SAPONARIA CALABRICA (Idem).—This splendid annual makes a charming bed, line, or edging if sown now. It should be sown where it is to remain; transplanting it is not desirable.

RASPBERRIES AND ASPARAGUS in a DAMP SITUATION (S. S.).—Raspberries thrive best in well-drained and moderately light soil; but your soil and situation will suit both if water does not lodge in the subsoil. If the soil is not light and well stirred to a depth of 2 feet it must be made so for the growth of Asparagus.

TURNING OUT BEDDING PLANTS INTO FRAMES (A. B.).—You will be doing well to turn your plants out of the pots, having previously put 6 inches of good turfy loam and leaf mould in the frame, and in this plant without disturbing the ball. The plants will make a better growth, and may by careful removal experience no greater check upon transplanting than if they were planted out from the pots; in fact, the plants will grow better and cover the beds much sooner. The plan is not new, having been several times recommended in the Journal. Expose the plants fully, and have them thoroughly hardened-off prior to planting out. The plants could not have a better position than one fully exposed to the sun.

NAMES OF PLANTS (J. G.).—*Asplenium chlorneum*. (Mars.)—*Scelaginella Martensii*; *Hepatica triloba*. (Falc. Hoff.)—1, *Lonicera angustifolia*; 2, *Pittosporum glabratum*. (R. Kemp.)—4, *Primula farinosa*, var.; 2, *Probably Pulmonaria officinalis*. (J. Wright.)—It is impossible to name seedling plants before they are more advanced without more definite information. We can find nothing resembling the specimen sent from North America. (S.)—1, *Adiantum tenerum*; 2, also *A. tenerum*; 3, *Pteris serrulata*; 4, *Pteris crenulata*; 5, *Pellaea rotundifolia*; 6, *Polypodium subauriculatum*; 7, *Adiantum curvatum*; 8, *Adiantum (Dore)* Bellangeri. (M. A.). 1, (?) 2, *Anemone officinalis*; 3, *Erica vagans*. (C. P.).—Garden Hyacinth and *Erica vagans*. (W. F. B.).—*Iberis saxatilis*. (Miss C.).—Garden Anemone. (A. B.).—1, *Gaultheria odorata*; 2, *Ajuga reptans*, garden variety; 3, *Tetranthera pilosa*; 4, *Diosma*, but which we cannot tell without flowers. (W. G.).—1, *Edwardia microphylla*; 2, *Pittosporum tenuifolium*. (C. F.).—1, *Asphodelus ramosus*; 2, *Eranthemum crenulatum*, variety; 3, *Prunus (Cerasus) Caproniana*; 4, *Eranthemum leuconeuron*; 5, *Bryophyllum calycinum*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending March 31st.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY EXHIBITIONS IN GENERAL.

CLASSIFICATION OF GAME FOWLS.

The best time for holding poultry exhibitions in summer is in the last ten days of June and in the month of July, as being just after the breeding season, which ends at midsummer, and before the moulting season, which often begins in August, though September and October are the regular moulting months, and all healthy poultry should be in full feather by November, or the first week in December. Summer exhibitions are, however, often injurious to very young poultry, which do not stand the removal or the penning at all well.

For the winter exhibitions the best time is December or November, but the week before Christmas is, perhaps, the very best time, as being well after the moulting season, and just before the breeding season, which should commence at Christmas. Fowls are, however, often more or less out of feather from July until December, a period of four months, and the breeding season lasts, properly speaking, from Christmas until midsummer, a period of six months, so that only July and December are thus left as the most proper months for holding exhibitions.

As to week days, Tuesdays, Wednesdays, Thursdays, and Fridays are the best days, leaving Monday for receiving, and Saturday for dispatching the birds again.

No exhibition should last for more than four days at the longest. For the two-day exhibitions, Wednesdays and Thursdays are the best days, as being in the middle of the week.

Exhibitions, however, cannot all take place at the same time, of course, and in the choice of time more regard is paid to local circumstances than to the reasons I have given, as, for instance, agricultural exhibitions, floral shows, horse or cattle fairs, market days, and similar gatherings, advantage of which is taken to hold a poultry show at the same time. August has always been the favourite month for summer exhibitions.

At exhibitions held in September and October the birds are displayed to great disadvantage, as in these two months adult birds, at all events, are most out of feather and never look well. August is the harvest month, and if this has anything to do with exhibitions, the harvest is in most parts of England over by September in ordinary years.

Yorkshire and Lancashire have always been the two great poultry exhibition counties; Yorkshire more especially so, as being the largest agricultural county in England. There are more poultry exhibitions in Yorkshire and Lancashire than in all the rest of England together, and I have always thought breeders in these two counties take more pride in exhibiting their poultry. North Warwickshire, perhaps, contains more Game fowls than any district in England, especially of the willow-legged, red-eyed, Black-breasted Reds; and Birmingham contains more Game fowls, especially Brown Reds, than any other town, though, I believe, the Manchester Brown Reds are superior in quality and hardness to those of Birmingham in general.

Poultry pens are, of course, hired by the committees of exhibitions, and some insist that the pens should be fitted with moveable perches, while others say that pens are better without perches. The pens should not be placed too close together, in the Game classes at any rate, as if not fitted with projecting side boards the Game cocks can reach out and get hold of each other's heads, as mine did in 1858, at the Crystal Palace Winter Show, much to their disfigurement.

Judges should, of course, be permitted to take the birds out of the pens for the purpose of handling them in judging, which some committees, I have heard, have objected to, saying it ruffles the feathers; but this no good handler would ever do, and the Game birds must necessarily be handled in judging. The pens should be large and lofty enough to contain comfortably a cock and two hens of the largest sorts of poultry.

THE BEST CLASSIFICATION OF GAME FOWLS FOR THE MIDDLE-SIZED EXHIBITIONS.

CLASS 1.—ORIGINAL-COLOURED AND OTHER REDS.

1, Brown Reds; 2, Black-breasted Reds. Both cup sorts and the most numerous sorts of all Game fowls.

CLASS 2.—DARK-TAILED SORTS, NOT ORIGINAL.

1, Duckwings and other Light Greys and Birehens; 2, Dark Greys and Dark Birehens; 3, Blacks and Brassy-winged Blacks.

CLASS 3.—SORTS WITH THE LIGHT TAILS.

1, Piles or Pieds; 2, Whites; 3, Red Duns; 4, Blue Duns. The

Dun sorts should be classed with the Piles and Whites, and not with the Duckwings as is generally done.

CLASS 4.—FULL-GROWN COCKS OF EACH COLOUR.

Best full-grown cocks of each colour. This is a popular class.

A STILL BETTER CLASSIFICATION, PERHAPS.

CLASS 1.—SORTS WITH THE DARK HENS.

1, Brown Reds (cup birds); 2, Dark Greys and Dark Birehens; 3, Blacks and Brassy-winged Blacks. This separates the Brown Reds and the Black-breasted Reds.

CLASS 2.—SORTS WITH THE FAWN-BREASTED HENS.

1, Black-breasted Reds (cup birds). Most numerous sort of all. 2, Duckwings. Very popular and numerous.

CLASS 3.—SORTS WITH THE LIGHT TAILS.

As in the above list. The Piles very popular and plentiful.

CLASS 4.—SINGLE COCKS.

As in the above list.—NEWMARKET.

(To be continued.)

BRAHMA POOTRAS AND DORKINGS.

I JUST write a line to correct the misapprehension that may arise in your readers' minds, through the heading which you have attached at page 246 to the communication made by me with reference to the extraordinary laying of one of my Brahma pullets, &c. The mixed brood I refer to as having been hatched on the 10th of March last were not cross-bred, as the heading would imply, but by mixed I simply meant that I made up a sitting of part pure Dorkings and part pure Brahmas' eggs, and of the chickens hatched from those eggs the Dorking pullets began to lay precisely at five months old, and the Brahma pullets not until two or three weeks later—a rule that I find generally observed with my birds, although in the answer you gave to your correspondent's question last week, you stated that the reverse is the case.

The pullet has laid every day since the 23rd ult. (one egg, however, being soft), and appears likely to continue doing so until further notice.—R. W. BEACHEY.

MANAGEMENT OF GEESSE.

ONE of my Embden Geese laid an egg weighing 11 ozs. I should advise "T. M. L." to leave the eggs in the nest, and let the Goose amuse herself just as she pleases; mine are so proud of their eggs, and go on the nest every day, even when they do not lay. The eggs are kept warmer than when they are removed. As the time of incubation draws near, the Geese cover the eggs very carefully with feathers and down, and they look snug and promising.

I like them to sit in an outhouse, and not out of doors. This is easily managed by shutting them in for a few nights previous to laying; and let the nests be in a secluded place.—L. B.

[The above reminds us of what was recently published in the *Norfolk Chronicle*.

"Norfolk has long enjoyed a most extensive and unrivalled celebrity for her poultry, and especially for her Turkeys and Geese. The number of these delicious birds sent from the county throughout the year, and particularly at Christmas time, is incredible. Besides those reared in our farmyards we have Geese produced by wholesale just beyond Magdalen Gates, by Mr. Bagshaw, who has a complete monopoly of the trade, not having any known competitor in the country; and some statistics respecting the rearing of these birds, and of their disposal, will probably not be uninteresting.

"Formerly Mr. Bagshaw reared a large number of Turkeys, but the demand for Geese so increased that he confined his Christmas business to the latter birds, still, however, continuing a general trade throughout the year. In the course of twelve months he produces from 60,000 to 70,000 fowls, of which about 30,000 are Ducks, principally of the Norfolk breed. About the last week in October the "baying-up" is the first preparation for the Christmas sale, more than one-half of the number required being obtained from Holland, and the remainder from various parts of this country. The fattening commences about the middle of November, and the largest number fatted at one time is 12,000—the number fatted this winter. As we have said, this business is carried on just beyond Magdalen Gates.

"The feed on which the fowls are fatted is barleymeal and brewers' grains, the former being ground by Mr. Bagshaw himself, so that he may not be exposed to the adulteration which

this commodity frequently undergoes; and the quantity of food required is about ninety coombs of barleymeal and sixty coombs of grains daily. The manure from such an immense number of fowls, fed upon such a description of food, is very valuable, and frequent applications for the sale of it are made; but as Mr. Bagshaw holds a farm close by his poultry yard he prefers to make use of it himself. It takes about six days to make preparations for the market, and about one hundred dressers are employed in the work, but as the birds are not drawn before they are sent to market, the giblets are bought with them. Of those killed for Christmas, some 4000 are sent to the goose clubs, and the rest are forwarded to the markets at Leadenhall and Newgate, where they are sold on commission. During the Christmas week no less than from seventy to eighty tons weight were sent away from Norwich by rail, the Geese averaging in weight from 9 to 16 lbs.]"

SELLING BOILED EGGS.

I DEB to ask your advice upon the following case. A person advertised in your paper some fowls for sale, first prize Birmingham. I wrote about that pen, and he said in answer that he had concluded to keep them, but if I wanted a sitting of eggs I should have an honest one, on the receipt of a post-office order for 12s.; and about ten days ago I received a note from the person saying that the birds of the first-prize pen were now laying, and a sitting of eggs were at my disposal, on the receipt of a post-office order. I accordingly sent one for that amount, and received a box containing thirteen eggs, one of which was quite cracked on one side, but dry, which excited my suspicion. When I broke it, you may imagine my surprise when I found it had been boiled quite hard. I broke two more and they were just the same. There are eight more looking just the same, and I have not the least doubt they have been boiled. What remedy have I? I withhold all names at present; but will give mine and his also, as I do not intend to be swindled in that way if I have a remedy.—J. L. L.

[Have the other eggs opened in the presence of a witness, and if they, or any of them, prove to have been boiled, apply to a magistrate for a warrant, and have the vendor apprehended and tried for the fraud. Since we wrote the above we are informed that the vendor returned the money, and stated, as is usual, that his man did it!—Eds.]

PACKING EGGS.

I saw a short time ago that you recommended bran as material for packing eggs in. I have been very unfortunate with eggs thus packed. Last year I purchased some Turkey eggs, they cost me about 14s., and I did not obtain a chick. I paid an extra shilling for packing, and the eggs were sent in bran, but although wrapped in paper were all lying against the lid, and five or six were smashed. The remainder were placed under a good sitter, but at the expiration of the time they all proved unproductive. There was no sign of a chick in any of them. I use moss when it can be had, and I find it answer very well. It wants drying previous to use.—L. B.

NOTES ON FANCY PIGEONS.—No. 10.

THE CARRIER.

THERE are by common consent of fanciers, and there have been for upwards of a hundred years, three varieties of Pigeons which stand higher than others in esteem, which have been cultivated with greater care, and in which certain properties have been raised to a higher standard. These are Almond Tumblers, Carriers, and Pouters. These birds have been treated in a similar way to florists' flowers. Now we know that the high-class fancy Pouter was derived from the common Pouter, and the Almond Tumbler from the common Tumbler; whence, then, must have come the fancy Carrier? Doubtless from the Horseman, a bird which now writers on Pigeons actually ignore. The Carrier came from the Horseman, not the Horseman from the Carrier, as the better comes by care and selection from the worse, just as the pansy came from the wild heartsease; though of course the worse will come from the better if there be a want of care, as the pansy will, if neglected, come back again—degenerate, in fact, to the wild heartsease.

There appears to have been, long before the English fancy Carrier, a breed of Pigeons which was useful, and therefore

bred in great numbers. These birds showed a great desire to return home, and would fly home great distances, and in days when travelling was slow a winged messenger was indeed valuable. It stands to reason that the birds that were quickest in flight and surest of reaching home would be most valued, and their form, colour, &c., would not be for a moment regarded.

There was, then, this class of useful Pigeon; useful, therefore valuable. Not a show bird—not a bird of points and properties, but of utility. Call the bird the Persian Pigeon, or the Turkish Pigeon, or the Scanderoon, or the Bagatin, or the Horseman; the bird is one and the same, perhaps some larger than others, but substantially the same. The bird was a bird of utility, and capable of being trained to greater utility, and naturally feather or shape, save as tending to utility, would be uncared for. The shape of these Pigeons was well suited to cleave the air; formed as we make the fastest boats, they were to other Pigeons—for example, the Hunt—what the University racing boat is to a barge. These Pigeons had also in common, notwithstanding differences of name, more or less of naked lump-like flesh round the eyes, and above and below the base of the beak. From these birds came, by care, and selection, and good judgment in matching, a florists' flower of Pigeons—the fancy English Carrier, just as in like manner came the Almond Tumbler and the English fancy Pouter.

One only objection is to be met—viz., that the best show Carriers are always black or dun, while Horsemen are of all colours. But this difficulty is answered thus: It is well known that some properties appear in excess attached to one particular colour, and that the best fancy birds of certain varieties of Pigeons are always of a certain colour—e.g., Fantails white, Dragons blue. The Carrier is the high-bred cultivated gentleman, the Horseman the useful labourer. As it is said to take three generations to breed a perfect gentleman, so it certainly takes several generations to breed a perfect Carrier. The Carrier has been a gentleman these 150 years probably, but he has refined and become a more perfect gentleman, just as a series of dukes have become in the same number of years. I look at a first-class Carrier and think, "Ah! your fine Eton and Christchurch, and good food, and good housing, and careful mating during the last 150 years have done wonders for you and your forefathers!" Then glancing at the shorter-necked, thicker-skulled Horseman I think, "You have not had such advantages, but you are the most useful fellow still."

I shall not go into the fancy points of the English Carrier, inasmuch as every Pigeon book gives them, but I will remark upon the bird generally. As the Pouter is the noblest-looking Pigeon that walks, so the Carrier is the most graceful; but to see well-bred Carriers to perfection you must not judge of them when in cages at an exhibition, for there they never look well; they stand at bay in a corner, and do not for one moment look at ease. But suppose you suddenly open a loft door, and there are a few Carriers within; they are bold enough not to fly, but unsociable enough to dislike and resent the intrusion, and stand on the peas giving a cross snort at you, and as they stand they look the very perfection of graceful strength. They remind me of the story of Queen Anne and her sculptor. Said the Queen, "You have made me in my statue look stern." "Madam," replied the sculptor, "God only can combine dignity and grace." Now, we may see the two combined in the Carrier. No wonder he has so long enjoyed the title, The King of Pigeons; no wonder an old fancier chopped off his head in royal fashion, and did not ignominiously wring his neck.

The colour of the Carrier in my opinion is best when black, and the blacker the better; then the statuesque look is more visible—that hard solid look which reminds one of stone. Unless I greatly mistake, the present show Carriers are many of them too small, just as we see too many show Game fowls erring in this matter of size. You want in the Carrier the appearance of strength, as well as grace, which size alone can give.

I hope that having now opened the subject of the Carrier eminent breeders of this bird will give us their experience, and do for it what has recently been done in these pages for the Pouter.—WILTSHIRE RECTOR.

P.S.—I cannot forbear expressing my gratification at the excellent articles which have appeared recently in this Journal on one branch of the fancy Pigeon subject, from the pen of Mr. Huie and others. The late Mr. Brent appealed again and again for fanciers to speak out, but in vain. Now, however, the publication of the work entitled "Pigeons" seems to have aroused our friends, and made them dip their pens in ink to a good purpose. "Pigeon-fancying," remarks Professor Huxley "is a great art and mystery," and I am sure it requires

very much taste and judgment. But there is another view of the pursuit which raises it greatly in value, and which was brought under my notice by reading the reports of the meeting of the British Association held last year at Dundee. One of those philosophers who are wise—no, no, who wish to be wise above what is written—was contending for half a dozen Adams and Eves to account for the different varieties of men—the black, the red, the white, &c., and was answered by a philosopher properly so called, who was a believer in his Bible, in this way—that the origin of the different races of men from one human pair was capable of proof by analogy as long as there were fancy Pigeons in the world, which we know all came from the Rock Dove. This good man and good philosopher was doubtless a Pigeon-fancier; all honour to him. Now there are no divergences, or differences, or diversities in the human family so great as those between the Shortfaced Kite Tumbler, black in colour and dumpy in shape, and the Pouter, white in colour, and 18 inches or more in height; and yet the two will pair and be prolific. So in the case of the Tumbler's atom of a beak and the Carrier's dagger-like bill; or, again, the smooth legs and feet of most Pigeons and the almost-winged leg of the Trumpeter, or the smooth crown and the turn crown, &c. Indeed, taking this view of Pigeon-fancying, it is not only a most interesting pastime, but the beautiful birds are themselves proofs of the truth of Holy Writ, and I delight to regard them as living rebukes of the unbeliever.

I must also beg to add one brief word concerning the union of the two London Pigeon Societies—a word of strong commendation of the step taken. It is just what is wanted. The paper issued by the Reorganisation Committee is admirable, and a plain proof that the old jeer about Pigeon-fanciers being uneducated is now wholly out of place. That paper might have been read before a learned society. I would venture to suggest that there should be a low rate of subscription for country members, who are not likely to be often in London, and yet would like much to be members. This plan would add considerably to the number of the subscribers, and greatly strengthen the Society. A county paper I know well did not pay when sold at a high price, but that now being greatly lowered, it pays well. Should this plan be adopted I shall be happy to belong to the Society, and ask my friends clerical and lay to do the same.—W. R.

BREEDING POUTER PIGEONS.

I HAVE just been reading Mr. Volkman's article in your paper last week, in answer to the remarks formerly made by Mr. Ure, Mr. Huie, and Mr. Stuart. As a Pigeon-fancier I am glad to see your columns open to discussion on this branch of the fancy. I only trust your kindness will not be abused. I thoroughly understand Mr. Volkman's views in respect to the breeding of the Pouter Pigeon. I am afraid, however, his enthusiasm for that class has carried him beyond his depth. Mr. Volkman, being an experienced breeder of long standing, must surely be aware of the insurmountable difficulties that debar the breeder of Pouter Pigeons from obtaining perfection, and less than that is evidently found fault with by our friend Mr. Volkman.

I am inclined to believe all has been and is now done to improve the Pouter in all its properties, that careful study, select matching, and access to an overflowing cash account in the bank could possibly do. It is a very easy matter to say that breeders should do this and that to obtain certain results in colour and marking along with the other indispensable properties; but surely Mr. Volkman is not so thoroughly ignorant, after his long experience in breeding his favourite Pouters, as not to know that that class cannot be put on a par with most other Pigeon classes; that anything like perfection can only be obtained very rarely, and that never with certainty, although hundreds are produced so near it that no one but a fancier, and he sometimes a whimsical one, could possibly discover a difference, and still this difference from the standard of perfection Mr. Volkman evidently thinks can be got over. Surely, if he will allow it, he is more intent in drawing out a few of the Scotch fanciers into a discussion, and leading them to give out unwittingly in the heat of argument a few valuable hints for the benefit of their English brethren, as to how they produce such magnificent specimens—for it is a very evident fact that the Scotch excel in this breed to a wonderful degree, and one would think that it was a decided misnomer to call this Pigeon the "English Pouter," seeing that it has emanated principally from Scotland during the

last century. However, I would not quarrel with a name, as that is of little importance so long as the Scotch breeders hold the laurels for producing the finest specimens ever yet exhibited, and therefore I think it can only be fairly inferred that they do not require any lesson how to breed.

As those of successful Pouter breeders of long standing, Mr. Ure's and Mr. Huie's views may be considered very valuable; also the remarks and information given us by the no less successful, though younger fancier, Mr. Stuart. I regret very much, however, to see an evident "worry" taking place by Mr. Volkman's erroneous and very inconsistent statement, when he unwarrantably tramps on their toes by insinuating that they had been breeding only for size, and "neglected" the property of colour and marking—telling them they should discard for a time the evident bad system they had adopted hitherto, which only produced size and symmetry, and little else to be commended. Now these assertions, without being facts, are apt to raise the Scotch blood a bit; and although Mr. Volkman is quite correct in advocating the exertions of all true fanciers to do all in their power to obtain as far as possible something like a standard, he should have stopped there, as a little reasoning would have proved to him that a Pouter Pigeon is such a combination of parts, so readily and easily effected, that no certainty could ever be relied on in production.

Would it not be much better if breeders and fanciers gave us a few practical hints as to their experience in the selection and matching of their birds, with the result? Some kind of information like this has never yet appeared in any publication as far as I have seen. Sterling facts would be eagerly read, as they might save the young fancier losing years in experimenting. Mr. Stuart very openly and candidly states one fact worthy of notice, and that is, his experience teaches him to select a moderate-sized hen to breed from. Now, here is a lesson that I dare say the inexperienced would have doubtless avoided if they had their choice.

Mr. Simpson, of Newark, gave us in a few lines downright straight-to-the-point information how he produced the best coloured Yellows and Reds. If Mr. Volkman would favour us with the description of the many birds he has bred, how he matched, and the results, as we are led to believe he has been very successful in obtaining all the properties, it will not only be more instructive, but may be more creditable to him as a breeder than all he could suggest should be done as "a fancier."

Your space is too valuable to be taken up with anything but useful information, and I trust the members of the fancy will not lose your favour by tiring you with irrelevant matter.—DEEDS SHOW.

A GUIDE TO CANARY-BREEDING.—No. 3.

THE birds on being introduced to each other will at first, most likely, evince anything but an amiable disposition, but this will in a day or two give way to a much happier state of things. The cock will be observed to feed his mate frequently, and she will begin to "nest," and will search eagerly for material with which to construct a habitation for her future progeny. The felt will supply this necessity, but a few feathers, or a piece of moss or soft doe hair—not cotton or wool, which is apt to become entangled in the feet—will afford her ample amusement. If this be not supplied, and no foreign material find its way within her reach, she will at once proceed to appropriate a portion of her lord and master's tail, or failing that, may watch her opportunity and seize him by the back of the neck in a most unfeminine way, swinging him backwards and forwards under the perch, till he falls and leaves her in possession of a monthful of feathers, a proceeding which he, like many other hen-pecked husbands, does not appear to dare to resent. If supplied with material and a suitable niche for her nest she will build one, and this is, as I have stated in a previous article, the common mode in the south. Different breeders adopt either plan. The felt nest has this advantage, that when the vermin begin to show themselves, and they most assuredly will, it can be changed at once, and an entirely clean nest substituted, which cannot be done so well with a nest of the bird's own construction, and those who know what pests these parasites are, are only too ready to adopt any plan of eradicating them.

In the course of a week or ten days after the publication of the hanns, the time varying according to the state of the weather, and the general health and condition of the birds, the hen will lay her first egg. The breeder need not be alarmed if the day before this most auspicious event he should find the

hen squatting in the bottom of the cage, generally with her head in a corner, with outspread wings, closed eyes, breathing rapidly, and looking the picture of misery, and as if at the point of death. At such a time it is best to leave Nature entirely to herself. Should the cock show any signs of molesting her he may be removed till the next day, but such is seldom the case, and the anxious novice who will, perhaps, be expecting to find his pet dead next morning, will find egg number one duly deposited, and the hen as well and as sprightly as ever. This complete prostration does not often happen. Should it, however, extend into the second day—that is, if she should not lay her egg in the morning, but be still evidently in a state of discomfort and pain, it will arise from her not being able to pass her egg, or being “egg-bound.” In this case hold her for a minute or two over the neck of a jug containing boiling water, exposing the vent to the action of the steam. Then replace her in the cage, and if the egg be not passed very shortly, repeat the operation, and if necessary, drop a single drop of olive oil on the vent, when, in nine cases out of ten, the egg will be passed without further trouble. Almost invariably one vapour bath is sufficient, and the egg is not unfrequently laid in the hand. Save it by all means, if possible; but these measures must be adopted with a view to save the bird, which must inevitably die if not relieved.

The Canary lays from three to six, and sometimes, but rarely, seven eggs, and has four or five nests in the season. Four is an average nest, five or six a good one. Take out the egg every morning till the third is laid. The object of this is to insure the eggs all being “chipped” together. In their natural state birds do not commence to incubate till they have laid their full complement; but the Canary will often sit on the first egg, which is not desirable, as the birds first chipped will necessarily be stronger than their brethren a day younger, and will secure most food, to the marked detriment of their less fortunate nestlings.

On the evening of the third day remove the felt in which the hen has been scuffling about for the last week, and substitute a clean one, nicely fitted to the tin, and securely fastened. Next morning the hen will have laid a fourth egg, and will at once begin to sit, seldom leaving her nest except to feed, and that not very often, as the cock, if he be a dutiful husband, will supply all her wants. The chipped egg, and all stimulating food, must now be discontinued.

The breeder can satisfy himself in a few days as to whether there be any vitality in the eggs by holding them up to the light, when the network of blood vessels can be distinctly seen, and in a day or two longer the egg becomes quite opaque. Such eggs are said to be “full,” others are worthless, and if at the expiration of a week they are perfectly transparent, they may at once be removed, as it is useless to distress the hen by allowing her to sit them out.—W. A. BLAKSTON.

GOLDFINCH AND CANARY MULES.

CAN you give me any information about breeding light-coloured mules between a Goldfinch and a hen Canary? I have been a breeder of mules a few years, and never have bred a buff or a yellow bird. I have bred from buff and yellow hens bred from yellow birds for twenty years.—L. S. D.

[Your correspondent wishes to discover a secret which many others would like to fathom. In my opinion mule-breeding is very much like a lottery—more blanks than prizes. There are, perhaps, more mules bred in this district than anywhere in England. I mean variegated Goldfinch and Canary mules. They are for the most part bred from a strain of birds known among breeders as belonging to the “marked mule tribe;” but what this “marked mule tribe” is, or whence its origin, I know not. I take it to be after this fashion:—

A breeder discovers that among a number of hens put up with Goldfinches one only shows a disposition to throw her young ones nearer the Canary than the Finch, and accordingly he experiments with her progeny—that is, with the young ones he may obtain from her by a Canary cock. These he breeds from again and again regardless of their feather; all he desires is to perpetuate a strain of birds which has a disposition to throw mules more nearly approaching the Canary than the Finch. By-and-by he becomes somewhat celebrated, and is reported to have a fine strain of mule-breeding hens. That there are such is beyond doubt the case, but to obtain them from their owners is almost impossible. The value attached to them and the interest centered in them is something beyond belief. There is some truth in the story of the pitman, who when dying said,

“Mary, hinny! I wad like to live the season oot, to see whether the ould dun hen wadn’t breed a clean mule!”

I have a cock and hen from a noted strain, which has not been contaminated with any cross for twenty-nine years. They are from the nest immediately preceding one which contained some first-class mules. I have also a cock and two hens from another noted strain, the property of the late T. Reid, Esq., Belgian Vice-Consul at Newcastle, a noted ornithologist, whose melancholy death a short time ago threw a gloom over this entire district. His stock was eagerly sought for, and I was fortunate enough to secure what I have mentioned. If your correspondent is very anxious to try for mules I will sell him one hen, but I cannot spare more. As may be expected from continued in-and-in breeding, they are very insignificant in appearance, their merit being in the certainty of their producing mules more or less marked.—W. A. BLAKSTON, *Sunderland.*]

CONSEQUENCES OF MISMANAGEMENT.

You have not yet made it clear to me what has been the cause of the comparative weakness of my Ligurians. I may, however, remark that a friend who has been looking at them thinks they are doing very fairly. Perhaps my alarm was partly owing to my expectation of something quite out of the common, and to my comparing them with a remarkably strong and active hive of good old John Bulls (which, however, I must say owe me something, as I got no honey from them last year, nor any swarm that I know of). This beautiful mild morning the Ligurians are out in numbers sufficient to satisfy any one, but on colder days they are decidedly less active than the English bees.

Pray tell me what was wrong in my driving last year. It was not by any means a large swarm which I drove. Was it too early, May 31st? I should like to know what course you would have recommended when the bees refused to go into a glass super, and were hanging out idle, and would inevitably have swarmed in a few days, which swarm I should probably have lost, as there were then no bushes in my garden. I have had some planted since.

The driven swarm, though not large, would, doubtless, have done very well had I been at home to feed it a little during the wet weather in July; but unless Italian bees are very sentimental, I do not see how its miserable end could have affected the parent stock.

My friend says that the whole of my mismanagement consisted in not stopping up the hives with tow during the snow in December, but I was again from home. Of course beekeepers should never go from home, but such things will happen.

May I ask if Lapwings in the garden would be injurious to the bees? Also, will you say whether dahlias are poisonous to bees?—S. S.

[If we have not already been sufficiently explicit we will now endeavour to be so. What was wrong in your driving was permitting the expelled bees to starve; what was wrong afterwards was allowing the stock which you had denuded of its surplus population to exhaust itself by over-swarming without applying a remedy; and what was quite as wrong as either was withholding an important fact, and endeavouring to throw discredit on the innocent victims of your own mismanagement. It is sheer nonsense to compare a stock which has been so treated with one that has remained intact, and then talk about “lazy” and “sentimental Ligurians” and “good old John Bulls.” Stopping up hives with tow during snow in December might very possibly result in a catastrophe by suffocation. Lapwings are insectivorous, but whether they would eat bees we are doubtful. We do not believe that dahlias are poisonous to bees.]

SHIFTING BEES INTO A NEW HIVE.

I HAVE a hive of bees, which is very strong; they did not swarm last year, and have wintered very well. The hive is a very old one (three or four years), and the briers that hold it together have given way in places. I wish, therefore, to know how I had better act, so as to remove the bees from the hive, and still preserve the brood, which is coming forward at this time of the year. I wish if possible to prevent from swarming, and yet still have a new hive for next winter. Do you think it would be most profitable to make an artificial swarm, as described in a February number, or to leave the hive alone till autumn, then drive the bees out of it, and esta-

blish them in a new hive? Do you not think the latter plan will come rather expensive with the feeding they will require? or will it be possible to drive them in August without destroying much brood?—CAROLUS.

[Your object of shifting the bees into a new hive without permitting them to swarm will be most completely attained by transferring the stock to a Woodbury frame hive in the manner described by us in No. 318 in reply to "Squir." Or you may permit the hive to swarm naturally, and on the twenty-first day after the issue of the first expel the remaining bees by driving, and add them to the last swarm, appropriating the combs, which will then be free from brood, to such purpose as you may see fit. If you drive the bees in autumn as you propose, it will be better to unite them to another stock rather than incur the expense of supplying them with sufficient food to enable them to build and store combs for the winter. This expense may, however, be very materially diminished if you are able to induct them into a hive already furnished with combs.]

COMB-CONSTRUCTION IN WOODBURY HIVES.

I HAVE a Woodbury frame hive in use, and like it much, but find that the bees do not fix the combs regularly on the line of the bars. How can this be obviated?—C. B.

[We always superintend the construction of combs in a frame hive ourselves, inspecting them from time to time, and promptly correcting any incipient deviation from the straight line. If yours are very irregularly made, the best plan will be to wait until the hive becomes well filled with bees (say towards the end of April or early in May), and then during the middle of a fine day drive all the bees into an empty hive, which place on the old stance, and then convey their original habitation in-doors, where such of the combs as require it may be either wholly or partially detached from their frames, and temporarily secured in the correct position by means of zinc clips and thin strips of wood tacked on in the manner delineated in page 84 of "The Gardener's Almanack." Bent combs must be set straight; and if not sufficiently pliable may be slightly warmed by the fire. Thickened parts should be pared down, but take care that the cells on each side are left of equal length, and that the "partition wall" of every comb is in the centre of each bar. It is better to remove the projecting Woodbury rib from the bars, and the bees will attach their combs to them with greater facility if their under surface be coated with melted wax. When the job is completed, and the combs arranged in their new apartment in the same order as that which they occupied in their old one, temporarily deepen the hive by putting an empty one of the same size, from which the frames, and crown and floor boards have been removed, on the top, and then place the whole on the old stance, knocking the cluster of bees out of their temporary place of refuge into the empty hive, and on to the top of the exposed frames, instantly pulling on the crown board. The inverted hive may be removed the next morning, and all, or nearly all, the artificial supports from the combs the day after.]

OUR LETTER BOX.

CHARACTERISTICS OF HOUDANS (*Lincolnshire Subscriber*).—It is with Houdans as with all other birds as soon as there is a demand for them. Fowls with some only of the characteristics of the breed are sold as pure specimens. We fear it has been the case with yours. Pure birds must have top-knots, beards, and five claws. The nearer the plumage approaches to unmixed black the better the birds; old hens will, however, have their top-knots tipped with white, and it is difficult to obtain the cocks without some mixture of white or yellow plumage after the first moulting, but red feathers are a serious fault. You would be disqualified if you showed unbearded birds. Alter your feeding by substituting once every day meal for whole corn, and consider your potatoes rather as playthings than as sustenance. Discontinue the eggshells. They make fowls egg-eaters. We keep large numbers, we never knew one broody.

DUCKINGS DYING (*Old Duck*).—Oatmeal is the best Duck's food. Mix with their meal fine gravel, and put a sod of earth covered with grass in the vessel that holds their food.

GOLDEN-SPANGLED HAMBURGERS' EGGS UNFERTILE (*A Constant Subscriber*).—We cannot guess the cause of the failure. We know to what most people would point, but we do not believe in such causes. It is a common complaint early in the season, but after results prove it a false one. There can, however, be no harm in trying another cock. It is often the result of bad sitting on the part of the hens, when, as in this season, broody ones have been scarce enough to make breeders anxious and less careful than they should be in assuring themselves of hens which are really staunch sitters. Such will sit partially just long enough to spoil the eggs, and then be as steady as possible. The morning frosts have been quite hard enough to spoil eggs. Have these been clear or rotten?

BRAHMA FOOTBALLS WEN-ROOTED (*H. P. L.*).—We should care little for the web between the toes. The outside toe is always short. When the toe is under the other, we should release it by cutting the leaders at the end.

SPANISH COCK WITH ENLARGED EYELIDS (*An Amateur*).—We suppose by the eyelid you mean the white face, the point of beauty. Benefit sometimes arises from frequent washing with strong alum, or vinegar and water applied cold and very strong. You must not cut it. If the eye is quite closed you must open it, and fasten it open with narrow strips of some adhesive plaster. They must remain on till the skin becomes contracted, and the bird can see again.

COLOUR OF COCHIN CHINESE EGGS (*Mona*).—Why the eggshells sometimes are white can never be settled. We have often noticed the same in all breeds of Cochins and Brahmas. Game fowls and White Dorkings will often lay brown eggs. Among our Cochins and Brahmas we have sometimes eggs almost as dark as chocolate "au lait," and others nearly white. We have often made it the cause of inquiry among our people. But one ever attempted an answer, and she (an old woman), said she had noticed that the eggs were dark, just in proportion to the heat of the weather: cold weather invariably made them pale. We have often noticed the eggs of White Cochins covered with white, apparently chalk spots. Although a perfectly white egg in a Cochin house, where that breed only was kept, would give us doubts, yet variety of colour or shade, however great, is not, in our opinion, inconsistent with absolute purity of breed in Cochins.

WEAK-LEGGED BANTAMS (*G. D.*).—We cannot advise you to breed from the Game Bantams again. We should avoid the strain, but if some of the pullets were good enough in points to make it desirable, we should put them to a cock that could not be akin to them. If the chickens were hatched under favourable circumstances, and provided with all that is necessary for successful rearing, they must be altogether wanting in constitution. Many birds will have white flights in their chicken wings, but moulting them out the first time. If, however, you have any intention to show, you must not breed from the cock you mention. It is probably the result of a cross that was made many years ago, and still throws back a little to Duckwing or Pile. Breeding in, or between brother and sister—indeed, anything that weakens constitution, has a tendency to produce white feathers.

HENS CEASING TO LAY (*An Amateur*).—Sharp frosts and cold winds are not helps to laying, neither will fowls lay every week alike. Your feeding is not good. If by meat you mean raw meat, they have far too much. They do not want it more than three times per week, and can do without it altogether. Potatoes are poor food, and rice is worthless. We prefer Indian corn whole to ground. Give this once every day, except when meat is given. The other two meals should be of whole barley once, and barley or oatmeal once, slaked with water. Cooked food, such as scraps of dried outside or knuckle of leg or shoulder of mutton chopped fine, is better than any raw meat. With the latter twice per day, the fowls become too fat, and not only lay less, but frequently die from the obstruction caused by internal fat.

BREEDING POULTRY PROFITABLY (*L. R.*).—We will endeavour to give you some details next week. In the meantime we can tell you that all Irish chickens at the present time are making 6s. per couple in London. Messrs. Howard & Fricker, of Leadenhall Market, are most respectable and trustworthy men, and would make quick and conscientious returns. Now, however, is the time to sell "profitable poultry." It is and will be very dear for the next seven or eight weeks, after that it will be cheaper.

HIVES (*W. Early*).—We consider any form of hive which will admit of supering to be superior to the collateral system, upon which Nutt's hives are made.

ASPECT FOR BEE HOUSE (*J. B.*).—We do not esteem aspect to be of primary importance, but prefer to place our hives facing towards the south. Any point between south-east and south-west will do.

LIGURIANISING (*G. J.*).—As you do not describe the hives in which your bees are domiciled, we are unable to advise you. Read Mr. Woodbury's article on "Propagating Ligurians," which appeared in No. 315, and if you want further information write to us again, stating where you are at a loss and what kind of hives you use. Assiduity in pollen-gathering is a tolerably sure sign of the presence of brood in a hive. The propagation of Ligurians may commence as soon as drone brood is pretty well advanced.

HIVES CONTAINING EMPTY COMBS (*H. M. K.*).—It is scarcely possible to overrate the advantage of having bees in hives already furnished with combs. If, therefore, the last year's swarms really died from starvation and not from disease, by all means induct fresh swarms into their old combs. You will find no difficulty in so doing, and it will be benefit rather than otherwise if it compels you to forego the now-exploded process of preparing the hives with balm, &c.

FEARS (*J. Z.*).—The following is all the information we can give you:—"Cleanliness and frequent sprinkling of the room with a simple decoction of wormwood will soon exterminate the whole breed of these troublesome vermin, and the best remedy to expel them from bedclothes is a bag filled with dry moss, the odour of which is to them extremely offensive. Others cover the floors of the rooms where fleas abound with leaves of the alder tree while the dew is on the foliage, to which these insects fondly adhere, and thus may be easily destroyed. Fumigation with the leaves of pennyroyal, or the fresh-gathered foliage of that plant sown up in a bag, and laid in the bed, are also remedies pointed out for the expulsion of fleas. The most effectual and speedy way to get rid of fleas or dogs is to pour sweet or train oil along the back, from the top of the rump to the back of the head, rubbing the sides, haunches, and flanks well with the hand until the oil be well incorporated with the hair. If this be done properly it is said that there will not remain a living flea on the animal in ten minutes after the application. They will throw themselves out upon the surface of the hair, of a yellow colour, with legs, &c., extended, and die almost instantaneously."

POULTRY MARKET.—APRIL 1.

FAMINE supply and famine prices. Some are gone, others are not come, and, therefore, salesmen's stalls are a "beggarly account of empty benches." The past week saw the arrival of the first Plover's eggs of the season. Many were sold at 5s. each.

From observations taken near London during the last forty-one years, the average day temperature of the week is 56.3°; and its night temperature 35.8°. The greatest heat was 77°, on the 14th, 1862; and the lowest cold 20°, on the 10th, 1860; and 15th, 1862. The greatest fall of rain was 0.73 inch.

THE DAHLIA AS A BEDDING PLANT—STORING THE TUBERS.

BY many flower gardeners the florists' Dahlia is voted a slow plant, its blooming period being somewhat short, and its habit not a little intractable; for it refuses to submit, or yields with a very bad grace, to the process of pegging-down. The appearance of those inevitable half-naked stakes is also decidedly inartistic, remaining an eyesore for many weeks during the early part of the season; and even the habit and form of both plant

and flower are sometimes said to be almost vulgarly ungraceful. This last allegation, however, I take to proceed more from the fact of the Dahlia being frequently met with in positions not the most picturesque than from any vulgarity in the flower itself. A stand of Dahlias at a flower show as usually seen does not present a picture of beauty calculated to throw a flower gardener into a state of ecstasy any more than do the long lines and borders of our florist friends, or the monotonously grand banks of our great growers; yet as a purely decorative plant, though not fashionable, the Dahlia is a gorgeous subject.

Like nine-tenths of all the bedding plants with which we have to deal, it is seen to most advantage in circular beds, and, up to a certain size, the larger they are the better; for it must be borne in mind that it is what is called in common parlance a large-featured plant, large both in leaf and flower, and to it as such the surrounding features must be assimilated. Its forte is producing an effect, not near at hand, of rich heavy luxuriance, the sort of beauty we are supposed to admire in the foreground of some highly-coloured southern landscape. Yet when planted in what are called the neutral or central beds of a large set it is also very effective, these acting as resting places for the weary eye, which, tired of scanning so much colour, intuitively turns to and is pleased to rest upon something more massive than dazzling, and which those who love to compare flower gardening to music would call the low rich notes of the piece.

For an isolated bed to stand entirely on its own merits—for instance, a bed of 15 feet in diameter—put one of the tallest dark sorts in the centre; round it, and at a distance of 18 inches, have five mixed sorts, but inclining to maroon; again, at 2 feet, another circle, in which bronze and crimson are the prevailing colours; and at 2½ feet, a third ring, composed of pink, lilac, and orange varieties, with an edging of Yellow Zelinda round the whole. Thus without any very regular gradation of colours we pass from sober to gay, the most striking being in the outer circles. In arranging the distances, the nature of the soil and situation must be considered; but as a rule Dahlias should be planted most thickly towards the centre of the bed, and there tied up to single stakes, the distances increasing with each circle. The plants towards the outside should be trained with three or more stems to as many stakes, while those forming the edging may be pegged down with more or less severity, so that the whole, when at perfection, will form a pyramid not stiff, yet possessed of that sym-

metry and balance, without which no circular beds can ever please the eye, no matter what their contents may be.

But the purpose for which we see the Dahlia most frequently used in the flower garden is as a backing for ribbon borders which have a wall or shrubbery behind. Now I know it is ungenerous, if not unjust, to find fault with anything, be it only a flower, without being able to give a reason for so doing. He who wrote—

"I do not like thee, Dr. Fell!
The reason why I cannot tell;
But, I do not like thee, Dr. Fell!"

penned a piece of doggerel which gives expression to a large amount of truth and bad logic; yet, substituting, of course, a Dahlia for the detested medical man, it exactly expresses my humble opinion upon this floral subject. Somehow or other Dahlias seem to make a ribbon border, which is at any time the very essence of cut-and-dried formality, still more formal. In borders similarly situated but planted in the mixed style, they do better, especially if relieved by plants of lighter form, such as Humeas, and when those immediately in front of them are of a height sufficient to hide their lower parts. Thus planted they form an excellent background for what is, when well arranged, a much more tasteful border than any planted ribbon-fashion can ever be.

Of bedding Dahlias proper there is now a rich variety and every year is adding to the number, but the selfs—white, yellow, scarlet, and purple—are those most suitable for flower-garden purposes, and may be introduced with advantage into any set of beds where very early flowering is not a primary consideration. They succeed best in a rather light, not too rich soil, a spadeful or two of something good being given them at planting time to afford them a start; after which their mission being to flower, they do so more speedily and profusely in somewhat poor soil.

A very attractive circular bed can be made by planting the following sorts in rings 18 inches apart, round a centre of Purple Zelinda 2½ feet in diameter:—First circle, Tiger, maroon; second, Prince Arthur, crimson; third, Crystal Palace Scarlet; fourth, Titian, yellow; fifth, Alba floribunda, white, and an edging of Mignonette, if on gravel, or Prince of Orange Calceolaria, if on grass. Prince Arthur, crimson, edged with bands of Cineraria maritima and Lobelia Paxtonii is also very effective, forming a quiet bed. The average height of these varieties being about 2½ feet, only those forming the outer circles require pegging-down; for the others stakes short enough to be entirely hidden should be used. Short, stout pieces of pea rods with part of the branches left on, placed among them when the flower stalks are well up, are also of great service, keeping them from swaying with the wind, and even in the case of those pegged down this precaution is sometimes necessary.

Passing over the propagation and culture of the Dahlia as sufficiently well known, allow me to say a word, however unseasonable, upon the storing of the roots over winter. Sanctioned by custom, it has long been thought a matter of great importance by many that the tubers should when taken up in autumn be carefully dried, and

kept dry until the following spring, and where a suitable place, neither so dry as to shrivel, nor so damp as to rot them, can be had, no doubt this plan gives ample satisfaction; yet they keep much better if laid, when large quantities of them are used, in long narrow heaps, mixed with sand, and carefully covered like Potatoes, care being taken, of course, to exclude both frost and rain. In spring they start more freely and at a lower temperature than those kept in a dry loft or room. Nature is in this, although not in every case, the best teacher.—*AYRSHIRE GARDENER.*

CAMELLIAS.

I do not suppose that it is useful that a person should grow a whole houseful of plants of any one kind to enable him to speak with any degree of experience on their cultivation, but that the same treatment which is found beneficial for a dozen plants is likely to be equally good for fifty or a hundred. I know that in reading the details of cultivation given from time to time in *THE JOURNAL OF HORTICULTURE* I never stop to inquire what is the number of the plants the cultivator grows, feeling that if I see good common sense, and am told that the plan has been successful, it is of very little moment to me what number of the particular plant he has under his care, and I am ready to take a hint from him, whether he be a large or a small grower; and, therefore, although my Camellia-growing is only in a very small way, yet the results that I have obtained are to me so satisfactory, that I may be pardoned, perhaps, if I detail it, and add a few notes on varieties.

There was a considerable amount of controversy last year in the Journal about the proper way to grow them. It interested me, and it seemed to me that the balance of argument was on the side of Mr. Pearson, of Chilwell, and I adopted in consequence his plan—*i.e.* I potted the Camellias in quite fresh loam taken off a pasture, about an inch in thickness, and torn up into small pieces about an inch square. I did this as soon as the plants were out of bloom, just as they were beginning to make their fresh shoots, taking care not to overpot them. They were then kept in a coolinery, where the Vines were just beginning to start, and kept syringed twice a-day. After remaining here until the shoots had acquired their full growth, they were removed into the front greenhouse facing the south, and placed on the front shelf with a blind of thick tiffany stretched over them. Here they were syringed as before; they were never put out of doors, never exposed to the weather in any way; and whether from these causes or not I do not know, but certainly I have never grown Camellias with anything like the satisfaction I have done these, for I had a quantity of bloom—so much so, that I was obliged to take off a large number, and had even then on a plant of Jubilee in a 32-pot nineteen blooms large and full. These results justify me in going on in the same way, and I shall certainly never adopt any other plan as long as I grow them. That equally favourable results may be obtained by other means I will not deny; the Ghent growers, for example, grow their Camellias almost exclusively in peat and leaf mould, and nothing can be better than theirs are. Still, having tried that and seen the superiority of those grown as I have detailed, I intend to adhere to Mr. Pearson's method of treatment. They like plenty of water and shade, and I prefer giving them both by artificial means rather than placing them under trees and getting the heavy rains upon them.

With regard to varieties, there are, as may be seen by referring to the Belgian catalogues, a vast number; but, as with every other flower, the lists contain many very inferior varieties, while in almost every colour now there are sorts whose shape and appearance it seems impossible to surpass. The following sorts I have grown myself, and give my opinion of them for what it is worth, holding as I do in this as in other flowers, that shape is of the greatest consequence:—

1. *SARAH FROST*, said to be of American origin; but wherever it comes from, a most beautiful flower, of a deep rosy pink colour, beautiful in shape, large and full. The habit of the plant, too, is excellent. Altogether first-rate.

2. *CONTESSA LAVINIA MAGGI*, a large, fine, striped flower, decidedly of the deep Carnation-striped flowers the very best we have. It has a tendency at times to come semi-double, my plant this year having produced several flowers of this character, and showing the stamens, but it is a noble flower.

3. *MRS. ABBEY WILDER*, an exquisitely-shaped white flower, most beautifully imbricated and pure in colour; its habit also is very good, and it flowers very freely.

4. *COMTESSE BOUTOURLIN*, a large rosy carmine flower, somewhat flat but striking in appearance; it is one of the large handsome-foliaged varieties.

5. *MRS. COPE*, an exquisite flower, white, faintly striped with pink; foliage small and neat; habit of the plant pyramidal. Altogether a desirable variety.

6. *MONTIRONI*, an old and well-known favourite, white, good habit, and free.

7. *JUBILEE*, another well-known flower of Messrs. Low, of Clapton; it is of most admirable habit, and very fine. My plant this year was a perfect picture.

8. *DUCHESSE DE BERRI*, an exquisitely shaped white flower, but the bud is large and hard, and I have found a difficulty in getting it to open; when it does it is very lovely.

9. *MAGNIFICENT*, a flower of very great size, deep rosy carmine; but I have found it so very double and so hard to open, that I have after two seasons given it up; moreover, it is somewhat coarse even when it does open.

10. *JENNY LIND*, an exquisite flower, faintly but regularly striped with pink; nothing can be more charming in its way than this is.

12. *REINE DES BEAUTÉS*, a lovely flower, beautiful delicate blush, of very fine shape, and well deserving of its name. It is said to be a sport from Mrs. Abbey Wilder, and partakes very much of the character of that flower.

13. *MRS. DOMERAIN*, a beautiful delicate light pink flower, shape excellent, habit good. It is quite a new variety, and not very well known, but it is very fine.

14. *RUBENS*, a small red flower, worth growing for the remarkable endurance of its blooms, which remain for a very long time on the plant without fading.

15. *CANDIDISSIMA*, an old variety, pure white, and well deserving of a place in any collection. Its habit does not seem to me to be very good.

16. *SACCOI NOVA*, another old sort, vigorous in growth, and very free; well worthy a place in a collection.

17. *CONTE BERNARDINO LECHI*, a new sort, which has not flowered quite yet; it seems to be a large flaked flower, and promises well.

18. *CUP OF BEAUTY*, an exquisite light flower, of first-rate shape and quality.

19. *COUNTESS OF ORKNEY*, a fine flower, of large size and exquisite shape, beautifully flaked with bright rose.

20. *AUGUSTE DELFOSSE*, a bright red flower, but somewhat starchy and faulty in shape.

21. *IMBRICATA*, an old and well-known flower of fine shape, red colour, and vigorous habit.

22. *DOUBLE WHITE*, an old and very favourite flower, pure white, of good habit.

23. *FIMBRIATA*, quite a gem, pure white, the edges of the petals beautifully fringed; a general favourite.

24. *MATHOTIANA*, a very large, nay enormous flower, very remarkable in appearance, but somewhat coarse.

I believe a very good selection may be made from these. I prefer No. 1, 2, 3, 5, 6, 7, 10, 12, 13, 15, 18, 19, 21, 22, and 23. Doubtless there are many others very good, but I only write of those which have bloomed under my own eye.—*D., Deal.*

PELARGONIUMS.

I wish to publish this short note on the very remarkable growth of a few Pelargoniums placed under my care.

Amy Hogg.—Colour bright purplish rose, flowers in very large trusses. This was a small cutting struck in August last. It has grown very freely. Some of my plants measure 2 feet through, and are beautifully formed.

Duchess is a soft rose lake, and is said to be of dwarf habit, but is a very strong grower here. It has immense foliage, the leaves measuring 9½ inches by 8 inches. The plant is young, being only the same age as Amy Hogg.

Culford Rose is another, and, perhaps, the best of the Zonal Pelargoniums. It has most beautiful foliage, almost as ornamental as that of a Gesnera. Its leaves measure 9 inches by 7½ inches.

Magenta is also a fine sort.

Clipper, Baron Ricasoli, Beaton's Indian Yellow, Black Dwarf, Dr. Lindley, and Orange Nosegay, are fine for growing as bedding plants, as well as for pot culture. They ought to have a place in every flower garden. When grown well they look magnificent in a conservatory. I have had them one mass of bloom in June, July, August, and part of September. It is as well not to allow them to remain in flower later than the

end of August, or beginning of September, if they are wanted to come in next season.

Cloth of Gold is growing here this winter and spring (so far) better than I ever saw it at any place. I have some plants 3 feet 4 inches in diameter. They look well in the conservatory or greenhouse when mixed with other well-grown *Pelargoniums*, if the foliage is fine.

The compost I use for the above-named plants consists of good turfy loam three parts, decomposed cow dung one-fourth, and white sand one-tenth, with a small quantity of bone dust. These ingredients are all well mixed together, and the whole is allowed to acquire a proper temperature before potting.—J. A. RONEY, *Wistaston*.

PEACH AND NECTARINE TREES OUT OF DOORS.

I NOTICE in a recent number a letter from "OBSERVER," entitled "New Glass Structures for Growing Fruit," in which he speaks of Peach and Nectarine trees having lost their constitutional strength, and as being now no longer hardy as in former years; and he goes on to say that "a wall heated while the sun shines on it, and a wall rendered cold by wind and evaporation when the sun is off, does not seem to suit these now tender plants, neither does too great an amount of moisture to the roots, especially in autumn, agree with their delicate constitutions. Cold, moisture-absorbing winds cause a chill. Bringing the trees in too close contact with walls by nails cripples them," &c.

Now, as statements of this kind often appear, particularly from advocates of orchard houses, against which I have nothing to say, inasmuch as they are delightful accessories to any garden, I should be glad to know whether in the south of England, or at all events south of London, your readers can endorse the opinions of "OBSERVER." For my own part, living in Sussex, I have never failed for the last six years to have a good crop of Peaches and Nectarines out of doors. I mention six years, because I did not attempt much gardening before then. I have been successful on the chalk and the stiff Wealden clay; but as the loam of the latter district is far stronger than any soil to be found on the chalk, I have more vigorous trees and heavier crops on it than I ever could obtain on the chalk. I have found a change from the chalk to the loam with a clay subsoil very beneficial; and I have one tree in particular, which labours under all the supposed disadvantages mentioned by "OBSERVER," a perfect picture of health and vigour, carrying regularly almost any amount of fruit, and, as a matter of taste, I prefer the flavour of a Peach off a good warm wall to that of those from orchard-house trees, with which, also, I have had no difficulty.

I think there is a tendency in these days to go into far too many extravagances in the way of "new structures," which may be all very well for those who have unlimited means, but are quite unnecessary for Peach, Nectarine, or Apricot trees in this part of the country, and I do not like to hear that some of our most choice and national fruits are becoming debilitated and unfit for out-door cultivation, for now that glass houses are so common, I imagine the true reason is that sufficient care is not bestowed on the things which our fathers brought to perfection in the open air, when, as far as I know, the winters were even more severe than they generally are now.

Only the other day I saw an Apricot tree quite 30 feet high spreading over the gable end of an old farmhouse. Its stem was like the stem of a large Apple tree, and a neglected grass lawn entirely covered its roots, which were, doubtless, far down in a wonderfully stiff and very wet soil, yet none of its limbs seemed to fail, and the farmer told me it almost always had an abundant crop. It has now quite a mass of bloom, as very little pruning has troubled it for many a year. Yet I hear and read that there are no old Apricot trees now-a-days, and that they must be grown under glass. If these fruits are required early they must be forced under glass; but with proper management, or even as this Apricot tree seems to say, with no management, they may be grown very well here without it.

Now, surely, one instance like that of this Apricot or my Peach tree puts a negative on the assertions of "OBSERVER," and reduces the facts that may have come under his observation from the region of climate or other source of supposed degeneracy to culture. The conditions which maintained that Apricot in health and fertility for fifty and more years would have maintained any number of trees similarly circumstanced, and the supposed evils of training a Peach tree on a wall,

which "OBSERVER" enumerates, cannot be the real cause of his failures, for, if not the cause, they are co-existent with my success. In gardening matters there is often something wanting; it is our business, by patiently comparing fact with fact, to find out what that something is.—H. NICHOLLS, *Hawkhurst Lodge, Burdocks, Horsham*.

OLD YEW TREE.

In the churchyard at Gresford, near Wrexham, Denbighshire, is a large old Yew tree. Its circumference at the ground, following the irregularities of the trunk, is 31 feet 6 inches, and at 3 feet from the ground, 32 feet 1 inch. At 3 feet 6 inches from the ground the girth, on merely passing the tape round, is 26 feet 3 inches. The tree has evidently been in declining health for some years, as some of the upper branches are bare of foliage, otherwise it is perfect; the trunk, a low one of 6 feet, particularly so, having no holes in it. The bark, however, is not good all round, still the stem is sound.

In London's "Gardener's Magazine" I find the following notice of this tree at page 536 of the volume for 1836:—"A Yew tree in Gresford churchyard, near Wrexham, is 29 feet in girth at 5 feet from the ground; height 52 feet, and the diameter of the head 36 feet.—J. E. BOWMAN, July 1, 1836." From the decay of the upper limbs the tree is studded with small branches or twigs at the setting-on of the branches, and at 5 feet no correct circumference could be arrived at.

The church is surrounded with Yew trees in a flourishing state, and few of less age than five hundred years.—G. A.

BOILERS FOR HEATING BY HOT WATER.

MR. R. FEATHERSTONE stated that his employer, Mr. Butler, purchased one of Clarke's water-jacket furnace boilers some two or three years ago, but that it fails entirely when he has to burn inferior fuel, such as they use in the garden, and that he objects to hollow firebars, as they tend to prevent thorough combustion.

I have had two of the above boilers at work for about the same period, and I can conscientiously testify that the heat is so intense in my water-jacket furnace, that it would melt cinders. Would this be considered thorough combustion? and if Mr. Butler's boiler will not do that, there is something wrong with the draught. Our boilers are heating piping for top and bottom heat for one thousand Cucumber plants. We sow in January, and cut fruit of the same plants in March.—JAMES WHITAKER, *Bark House, Prescott*.

ROYAL HORTICULTURAL SOCIETY.

APRIL 7TH.

FRUIT COMMITTEE.—George F. Wilson, Esq., F.R.S., in the chair. Mr. W. Hallett, of Cossington House, Bridgwater, sent two braces of Cucumbers, one named Cossington Hero, and the other Hallett's Perfection. Mr. S. Brister, Whitton, near Hounslow, sent a seedling Apple which was not of any value; and Mr. Whiting, of The Deepdene, sent specimens of Wilcox and Wilcox Improved Broccoli.

FLORAL COMMITTEE.—Another most successful meeting was held this day; it is most gratifying to witness how much interest these fortnightly meetings have excited; the liberal support of so many exhibitors tends to the success, and deserves the thanks of the Society. It is now evident that the spirit of horticulture, pure and simple, is in the ascendency, and we may now confidently expect better days for the Society. Indeed, the collection of hybrid *Coleus*, exhibited from the Society's own gardens at Chiswick, must have convinced the most sceptical that the dear old garden is still vigorous. Mr. Banse's seedling *Coleus* cannot be too highly commended, they are vigorous and a vast improvement in this family. All honour be to the indefatigable hybridiser, who is so devoted to his calling. Without doubt they are one of the greatest advances yet made in this direction. These plants will be highly esteemed in the horticultural world, and will be very beneficial to the Society.

The awards made were numerous. Messrs. Veitch exhibited several new plants, especially Orchids, but some not being recognised by name they must await their awards. Some of them were very fine, especially an *Anguloa*, which is of first-rate merit. A special certificate was awarded for *Angreum citratum*; a first-class certificate for *Pandanus gramineus*; and a special certificate for the beautiful collection of Orchids.

Mr. Davies, Ormskirk, sent a hybrid *Azalea*, called *Odorata*, profusely covered with white flowers and very ornamental; it received a first-class certificate. Messrs. E. G. Henderson sent *Primula elatior* Golden Prince, a true *Polyanthus* with deep yellow trusses, most

beautiful, and as a spring decorative flower invaluable; it received a first-class certificate; cut specimens of *Trichopilia snavis* from the same firm had a special certificate, and *Trichopilia* var. *splendens*, had a first-class certificate. Mr. Williams, Holloway, exhibited a fine specimen of *Imantophyllum* miniatum with numerous heads of flowers, and a special certificate was awarded for excellent cultivation. Mr. Baxter, gardener to C. Keiser, Esq., sent *Amaryllis Othello*, a very dark red variety, smooth in outline and good, and received a first-class certificate. A special certificate was awarded him for the collection of seedlings, some of them of good character. Mr. Turner, of Slough, was awarded second-class certificates for seedling *Auriculas*, green-edged, Col. Champneys; and grey-edged, Competitor; of Selfs, King of Crimsous, a beautiful flower, had a first-class certificate; Jessie, dark, one of the second-class; Princess, a deep purple, a first-class certificate. A special certificate was awarded for the collection of show *Auriculas*, and also for the collection of Selfs. These latter are called *Alpines*, but the term is inadmissible.

Mr. Trussler, gardener to R. J. Kay, Esq., received a special certificate for a box of cut *Camellias*; Mr. Green, gardener to W. W. Saunders, Esq., a special certificate for a very nice collection of plants, many of the minute *Orchids* among them. These discarded plants of the great orchidists Mr. Saunders delights in cultivating, and most truly beautiful and interesting they are. Mr. W. Paul received a special certificate for a collection of superb cut *Roses*. He also exhibited some very small plants of *Likodendrons* beautifully in flower. They were grafted last September, the flower-buds being then formed, kept in a cool place till spring, and then received a little heat. He also sent a collection of *Variegated Zonal Pelargoniums* which have been previously noticed.

Mr. Pilcher, gardener to S. Rucker, Esq., was awarded a special certificate for a remarkably fine specimen of *Odontoglossum pulchellum*; and Mr. Farley, gardener to F. Pryor, Esq., Digswell, a special certificate for a basket of cut flowers of *Thunbergia Harrisii*, most delicate in colour. Messrs. Smith, of Dulwich, received a second-class certificate for *Cineraria Pandora*, and a special certificate for a collection of *Cinerarias* and a collection of *Variegated Zonal Pelargoniums* of much interest. We must take this opportunity of stating that at this early period of the season the Committee decline adjudicating on the merits of *Zonal Pelargoniums*; to do otherwise would be equally unfair to the plants as to the Committee. Exhibitors should remember that this is not the time for judging these plants; it is utterly useless to profess to know from the present appearance of any *Zonal* what it may present in six months' time. The Committee consequently request that all *Zonal Pelargoniums* should be sent later in the season.

Mr. Bragg exhibited a large collection of *Pansies*, rather rough in outline, but sufficiently meritorious to receive a special certificate. Mr. Moore, gardener to the Earl of Shrewsbury, sent a beautiful collection of cut specimens of *Orchids*, which were destined as a present to Her Royal Highness the Princess of Wales, but they were sadly bruised in their journey to Kensington. A special certificate was awarded for a collection of *Orchids* from the Society's gardens.

There were numerous other exhibitors. Mr. Mann, of Brentwood, sent some splendid specimens of his *Zonal Pelargonium*, Lord Derby, but owing to the rough treatment received from the railway porters they were completely destroyed. However, the character of the flower is still first-rate; it is, doubtless, the finest *Zonal* in cultivation. Messrs. Paul & Son, Chesham, sent a collection of spring flowers. Messrs. Henderson, Wellington Road, *Dianthus Mossieux*, and *Zonal Pelargonium Curiosity*; also a new *Orchid*, *Nasomia cinnabarina*. The Committee were rather rebuked by Mr. Bateman in his remarks on this plant not being certificated; but the Committee have their rules, which we think are to be defended. Of the rarity of a plant, or of its intrinsic value, unless specified, what can the Committee know? and if rare and valuable if not effective and distinct, it cannot surely deserve commendation. Mr. Kinghorn sent cut flowers of his beautifully-striped *Azalea Lizzie*. A first-class certificate was awarded this as a seedling plant in 1867, and it maintains its first-rate character.

GENERAL MEETING.—J. Bateman, Esq., F.R.S., in the chair. After a vote of thanks had been passed for several donations of plants, &c., to the Society, twenty new Fellows were elected, and the Harrogate Horticultural Society admitted into union. The awards of the Floral Committee were then announced, and Mr. Wilson, in stating that the Fruit Committee had made none, remarked that at this season, when fruit is very scarce, the inducement of prizes is needed to bring it forward, and that such would be offered at the next meeting. At the last there was a very fine collection of Apples, which gained the second prize, and Mr. Cox, of Redleaf, who exhibited them, had sent a letter which should have arrived at the same time, but did not, informing the Committee that the fruit had been preserved in cork dust. The appearance was excellent, and the flavour in nowise altered. Mr. Wilson added that he had tried the same material with *Joséphine de Malines* Pear, and the fruit so kept was very much better than when otherwise preserved.

The Rev. M. J. Berkeley, being then called upon by the Chairman, said that at the last meeting a very pretty plant was exhibited under the name of *Cypripis Lacourii*, and received a second-class certificate, but he had since found that the plant was very widely distributed over

the world, being found both in the East and West Indies, and in the Society Islands, and that its proper name is *Kyllingia monocephala*. He then congratulated the Meeting on the fine hybrid varieties of *Colens* which had been raised by M. Banse at the Chiswick gardens, and pointed out a curious specimen of *Odontoglossum gloriosum*, in which the flower had two distinct lips, and some *Stocks* exhibiting a malformation similar to that which is so frequent in *Roses*, all the flowers producing a new spike in place of a pistil. A species of *monid* which had all the appearance of a sea-weed, and which Agardh had called *Phycomyces nitens*, was next exhibited to the meeting, and Mr. Berkeley said that having developed itself on barrels of grease in a storeroom in London, he had received some of it, and, being successful in fruiting it, he had found it to be *Macro phycomyces*, which has a very disastrous effect on grease by exhausting all the fatty matters. Examples of the effect of fungi on woods were then shown and among others a section of a trunk of an Elm tree, showing the mycelium on one side, and on the other the fungus developed; also a piece of Oak wood, in which the course of the mycelium was very distinctly defined. An example of *cremactis* was likewise shown, in which the wood had become almost entirely converted into coal.

At the last meeting, Mr. Berkeley proceeded, Mr. Wilson Saunders had made some observations on the very interesting subject of raising *Orchids* from seed. The late Mr. Joseph Henderson, one of the most acute observers with whom he had ever been acquainted, had found at first no trace of an embryo in this class of plants, but one was eventually developed amidst a mass of cellular tissue, and consequently its rudiments must have been there. He (Mr. Berkeley) would advise all who might be desirous to try Mr. Dominy's plan of hybridisation, to endeavour to raise the seeds on wood covered with moss. At the last meeting there was also a bunch of *Grapes*, kept by placing the footstalk in water (see page 222), and the opinion of the Committee was condemnatory of the proceeding, the berries being pronounced vapid and insipid, and he could now advance a reason which did not occur to him at the time. Supposing that the charcoal in the water had the power of absorbing all noxious gases, the water taken up by the stalk would be pure water, not sap; and if by the process of endosmosis and exosmosis it passed into the cells, something would also pass out, and that something in all probability would be saccharine matter. Mr. Berkeley concluded by remarking, with reference to hypocaust heating, that some doubts had been expressed whether noxious gases might not escape into houses heated by that mode, but Mr. Martin had informed him that it was utterly impossible for anything of the kind to take place.

Mr. Bateman said he had a grievance to bring before the meeting. It so happened that ten or twelve years ago he had introduced from the continent a perfectly hardy evergreen Bamboo, called *Bambusa metake*. It would attain the height of 14 feet, and no amount of frost affected its large handsome leaves. Great, however, was his dismay last spring to find that the plants were covered with brown processes, and by no means in a healthy state. This he at first thought was the effect of the winter, but afterwards he found that it was an attempt to flower. On returning from the continent this year he had found the flowering repeated, and he now exhibited specimens in that state. He was very much interested in the fact, inasmuch as no other person's plants, so far as he was aware, had taken similar liberties, but he was inclined to ascribe this circumstance to the fact of his having the plant before any one else, but in a year or two other people might find themselves in the same position.

Mr. Wilson Saunders said that the plant was flowering very freely with him, and had thereby lost a portion of its beauty. He would advise Mr. Bateman to cut it down, and fresh leaves would spring up.

Mr. Bateman said he would put it to the vote that Mr. Saunders should be called upon to cut down his plant first.

Mr. Saunders replied he had already tried that, and with perfect success.

Mr. Bateman, in commenting on the *Orchids*, first referred to *Odontoglossum luteo-purpureum* from the Bishop of Winchester's gardener, Mr. Laurence, and remarked that the Bishop in his long illness had found much solace and comfort in his *Orchids*, and Mr. Bateman felt sure that all would join him in the hope that they might again soon see the Bishop at their meetings, where he had been a constant attendant. Among the *Orchids*, Messrs. Veitch's collection held the first place. The plants of which it consisted were natives of all quarters of the globe, but Africa, including Madagascar and the Mauritius, he thought on this occasion bore the palm. Especially noticeable among the Africans was *Angraecum citratum*, which two years ago was shown in a very small state, but was now much improved. Passing to India, where, in Nepal and the adjoining districts, the head-quarters of the beautiful *Dendrobies* were fixed, we had a *Dendrobium Falconeri*, which Messrs. Veitch were not allowed to carry off from Liverpool for less than £70. With regard to *Epidendrum paniculatum*, it was not very striking last year, and even this its vigour was far from equal to that of wild specimens, but what would it be when it formed one dense panicle of lilac flowers, of which that on the plant before the Meeting could only be considered a branch? An *Angulou* from Peru, with a curiously-jointed lip, was then noticed as remarkable for the movements of that part of the flower when touched; but among splendid plants the place of honour was certainly due to the *Odontoglossum pulchellum* from Mr. Pilcher. Mr. Bateman then took some exception to the Floral Committee's having

passed over *Nasonia cinnabarina*, which not only forms tufts of brilliant vermilion flowers, but is moreover a cool Orchid. A noble lord in his own county, Lord Shrewsbury, or rather his gardener, had sent a collection of cut Orchids, some of which were to be presented to Her Royal Highness the Princess of Wales, and others were to be distributed after the meeting. Among them were *Dendrobium Wardianum*, which was at one time confounded with *D. Falcoueri*. Mr. Marshall had *Odontoglossum triumphans* with twelve flowers on a spike. O. Hallii was flowering very finely with Mr. Rucker, and from his (Mr. Bateman's) own garden there was *Blotia Sherrattiana*. Messrs. E. G. Henderson had sent a fine exhibition of *Trichopilia nanus*, from Costa Rica, and Mr. Wilson Saunders a very interesting collection of that peculiar but very interesting race of Orchids which he delighted to cultivate. *Odontoglossum macranthum hastiferum*, from Lord Lonsborough's garden, Mr. Richards, was also noticed. Mr. Bateman remarking that this *Odontoglossum* had been introduced thirty years ago, but had been lost through not being kept cool enough, but now, through the enterprise of Messrs. Veitch it had been reintroduced. Mr. Bateman added that he had seen it with forty or fifty flowers in a spike.

Mr. Bateman next offered some remarks on *Dahlia imperialis*. About the beginning of last November he reached Cannes, where the climate is so mild that plants from the Cape, Australia, and Mexico may be successfully grown in the open air. On entering Mr. Wolfeld's garden he caught sight of a plant at a distance of 50 or 60 yards, with large French white flowers, which he at first took to be those of a white Lily, but when he reached the plant he found it was a *Dahlia*. He was told it was *Dahlia imperialis*, which had been introduced by a collector named Roezl. Mr. Bateman, in continuation, said that when at Chatsworth, some years ago, he was shown by the former President of the Society, the late Duke of Devonshire, a *Dahlia*, which was expected to grow 30 feet high; but it had never been thought to try it otherwise than out of doors, and nothing more was heard of it. This was twenty-five or thirty years ago, and whether the present plant was the same or not he could not say. Mr. Salter, of Hammersmith however, had visited the nursery of M. Hubert, at Cannes, had there seen it growing 13 feet high, and had introduced it into this country. When he (Mr. Bateman) had seen it an exceptional frost, such as did not occur at Cannes once in four or five years, had curtailed its beauty, of which, however, some idea might be formed from the dried specimen before the meeting, and of which the flowers measured nearly a span across, these being produced in branched panicles of great size; and when in flower this *Dahlia* was certainly one of the most magnificent out-door plants he had ever seen. Having with him a copy of Pritzke's "Iconum Botanicarum Index," he found that *Dahlia imperialis* was figured in "Gartenflora," where there is a very long German account of it, for a translation of which he was indebted to Miss Richards, and a portion of which he would read.

"We openly confess that we read our friend Roezl's first account of this new *Dahlia* with a somewhat incredulous smile, and perhaps the same may happen to many a reader of the 'Gartenflora' when he casts the first glance at the accompanying plate, which shows him a *Dahlia* of a very extraordinary—I might say undreamed-of and surprisingly new appearance; for a *Dahlia* with bell-shaped, white, lilaceous flowers, with a pyramidal, hundred-blossomed, caudal-shaped inflorescence appears to belong, judging from what we have hitherto known of Dahlias, to fairy world.

"To truth, *Dahlia imperialis* appears to be new to the scientific world, for we cultivated several specimens last year in the botanical garden at Zurich, and brought them into blossom, and convinced ourselves that it did not belong to either of the species described in 'Prodrum,' and in 'Walper's Repertorium.'

"Roezl's short and convincing information read somewhat like the following:—This new *Dahlia*, which is imposing even as a leaf plant, will make as great a sensation as the first single *Dahlia* did. It blossoms on pyramidal flower stems, with from 150 to 200 large, white, bell-shaped, nodding flowers, like a Yucca or a giant white Lily. I consider it the most beautiful and valuable of my importations. It will, I hope, completely justify its proud name of the Emperor's *Dahlia*, even in European gardens; and as we (Messrs. Roezl and Besserer) place our entire confidence in it, we try, by representing it at its first blossoming, to make it known. At the same time as this information, which excited our curiosity and expectation in the highest degree, we received at the end of May of last year (1882), a large chest with about two hundred tubers, pretty much like the ordinary *Dahlia* tubers, but of a longer, more stretched-out shape. As the season was already pretty well advanced, they were all immediately planted in the open ground, in groups and beds in the garden, and a large number, on account of want of space, in a poor manured Potato field. All the tubers threw out well, several three or four tubers, which even to the strongest were immediately broken off, and took root more quickly and with greater certainty than tubers of the ordinary *Dahlia* planted at the same time for comparison, which sufficiently convinced us that the *D. imperialis* would support itself and spread rapidly, even if it did not ripen seed. The specimens planted in the garden soon reached the height of 5 to 6 feet, while those in the poorer ground were from 3 to 4 feet. The stately growth, the large, elegantly double, almost triple pinnate, gladsome green leaves make at least as beautiful a leaf-plant as the most beautiful of the *Wiganas*, *Solanums*, and *Nicotianas* at present so highly prized. Singly, in the grass, with well-manured ground, the *D. imperialis* will figure in the first rank as a leaf plant even before its flowering time commences, as it does not lose its lower leaves. As soon, however, as it unfolds its flower panicles, richly covered with large white Lily-bells, it will far surpass the most beautiful of the ornamental flowers which are at present so much liked. We ought not to, neither will we keep silent, that last year (for our impatience can be well understood), we had to wait long, but too long before we discovered the first buds. Not before the middle of October did the longed-for buds show themselves; but now, as by

enchantment, several specimens, the most luxuriant as well as the poorer, were covered with buds; the top as well as the side branches produced whole bunches of buds. There was no longer any doubt that Roezl did not exaggerate when he spoke of 150 to 200 flowers on a panicle, for on our strongest specimen we could show a still larger number of buds."

As to *Dahlia imperialis* ever taking its place as an out-door plant, continued Mr. Bateman, the idea was absolutely preposterous. It must, therefore, be grown out of doors in summer, and moved into the conservatory in September. He hoped that the tubers which he had shown the meeting would, under Mr. Fyles's or Mr. Barron's care, produce flowers before the end of the year.

Major Trevor Clarke said that two years ago he had purchased a packet of seed, said to be that of *Dahlia imperialis*, and whether the continental nurserymen had "done" the English, or the English had "done" him he did not know; but the produce was a common *Dahlia* of the most abominable description, and he could only say, *Caveat emptor*.

The proceedings closed with a vote of thanks to the Chairman, and the announcement that the next meeting would be held on the 21st instant.

THE GREAT INTERNATIONAL EXHIBITION AT GHENT.

(Continued from page 256.)

A VERY large number of new and very rare plants was sent by Messrs. Veitch & Son, Messrs. Lindon, Van Houtte, Ambroise Verschaffelt, Jean Verschaffelt, and a host of other eminent cultivators. These were exhibited in a very long, heated, conservatory-like building, commanding a view of the great hall beneath, and in it were plants enough to fill two such buildings.

In Mr. Ambroise Verschaffelt's collection were *Dioscorea nobilis*, with rich velvety foliage dusted with lemon spots, with a large, broad, irregular, lemon stripe in the centre of each leaf. *Cordylone Guilfoylei*, which is a variegated *Dracena* with pale yellowish white and green leaves. These are two valuable plants. In the same collection was a very pretty and distinct dwarf-growing *Dieffenbachia* named princeps. Mr. Linden had a very interesting group, amongst them *Iresine sp. nova*, a narrow-leaved kind with beetroot-coloured foliage and bright red midrib; *Maranta virginialis* and *Maranta virginialis macrophylla*, the former good, the latter particularly so, and a welcome acquisition. Both partake of the habit of *M. fasciata*, and are very similar to *M. Veitchii* in marking, but lighter in colour. *Cochlostoma Jacobianum* is a very curious plant with *Medinella*-like flowers thrown out from the base of the leaf. *Lasiandra macrantha* is a *Melastomaceae* plant, blooming freely in a small state with rich-coloured *Pleroma*-like flowers. Messrs. Veitch & Son sent a valuable lot of plants. Amongst these were some fine new *Dracenas*, especially *Deunisoni*, *Chelsoni*, *Moorei*, and *Gibsoni*, the latter richly coloured and a fine thing; *Alcacia Jenningsii*, a small-growing species with the foliage distinctly marked with dark velvet and bright green stripes, a lovely plant; the pretty *Primula cortusoides alba*; some handsome *Retinosporas*; *Lomaria ciliata*, a beautiful Fern; *Clematis John Gould Veitch*, double, pale lilac colour, quite hardy and a fine kind; *Dieffenbachias* *Weirii* and *Pearcei*; *Pandanus Veitchii*, an extremely fine thing, beautifully striped with white; *Cinchona* species; some new *Crotons*, *Philodendron Pearcei*; *Hippeastrum pardunum* in flower; a very promising *Apheclaudra*, and other things. In other collections we observed *Curelugo sumatrana* fol. var., a handsome variegated plant, somewhat resembling an *Aspidistra*; several new Palms, particularly *Geonoma Seemannii*, which promises to be as fine as *Verschaffeltii* *splendida* and is distinct. M. Jacob Makoy, of Liege, had some very interesting new plants, amongst them *Panicum plantatum foliis nivo-vittatis*, with woolly green leaves striped with white. *Cocos Weddeliana* is a most beautiful small-growing Palm with delicate graceful foliage; and *Clerodendron Bungeana* variegata, of which several plants were shown, will, if the variegation comes whiter, be valuable, but as exhibited its colours were not clear enough. There was a batch of beautiful *Acer*s in pots, particularly *multifidum*, *multifidum purpureum*, *ornatum*, *Fredrick William*, and *polymorphum sanguineum*, all varieties of *palmatum*. These are all small-growing, cut-leaved kinds, varying in form and colour, and are most valuable for decorative plants, especially for table decoration. A new species of *Pandanus* precisely like *P. elegantissimus* in form, with a strongly-marked glaucous base, promises well, and we noticed two or three forms of this plant in M. Van Houtte's nursery. *Dioscorea sp. nova*, is a very interesting form of the *Sundew*; and *Gloxinia hypocyrtiflora*, a new plant from Ecuador, is much more curious than pretty. *Gymnogramma ramosa cristata aurea* is a crested form of the Gold Fern, which, also, is more curious and pretty. We have noticed what we consider the best of the new plants. There were many other things, but as they are not likely to be popular in England, we pass them by. Some seedling *Begonias* were exhibited, but only one, a seedling of *M. Vandeubeeke's*, which appeared to be a sportive and curious form of *B. smaragdina*, arrested our attention. Two variegated hardy plants but little known, but most valuable, *Hemerocallis Kwano variegata* and the silver variegated form of *Dentzia gracilis*, deserve

to be in every garden. We saw nothing striking in new *Caladiums*. Of the new *Azaleas* and *Camellias* we will speak presently.

A long and spacious room was devoted to *Agaves*, *Amaryllis*, *houquets*, table decorations, &c. *Agaves*, *Yuccas*, &c., many of them of great size and value, and numbering some three to four hundred plants, were exhibited. These are much esteemed on the Continent, but are little valued in England.

What a glorious display of *Amaryllis*!—over four hundred plants, and such variety of colour! Some of the seedlings were grand, and M. Van Houtte has the finest strains. All were grown in small pots and were admirably bloomed, and they must become more popular in England. They can be hybridised to any extent, so as to get perfection in form and colouring. Mr. Charles Turner drew our attention to a small flower, a seedling rich in colour and of exquisite form, but passed over by the Judges. In his hands this and a half dozen others we could have picked out would soon have given birth to some grandchildren!

The *Azaleas*, which, as in our own shows, were the most attractive of colour objects, were smaller than our own, but no less dazzling. Three seedlings, however, appeared very desirable in point of colour, surpassing everything which approached them in brilliancy—namely, *Roi d'Hollande*, a valuable variety of a rich vermilion, spotted on the upper segments, and remarkable for smoothness and substance; *James Veitch*, a most brilliant tint of magenta rose; and *Coloris nova*, a rich glowing crimson, quite distinct and very fine.

New *Azaleas* were, however, so numerous and fine that it is somewhat difficult to tell which were really the best. We especially noticed—*La Victoire*, bright red, with spotted petals; *La Vestale*, shaded lilac pink, fine substance, size, and form; *Thisbe*, bright salmon red, extra fine form; *Meteor*, shaded lilac red, fine form; *Raphael*, a very fine double white; *La Superbe*, intense rich dark orange scarlet, smooth and fine; *Madame Leon Maenhant*, a peculiar shade of red, with rich violet-spotted top petals; *Madame Van der Cruis*, a very large semi-double rose; *Rachel Von Varabagen*, an extra fine single rose; *Gloire Avant tout*, white, and occasionally striped with pink; *Bayard*, a light scarlet, with rosy carmine spots, very fine; *La Déesse*, pale rosy salmon, margined with white, extra fine; *La Paix*, light rosy purple, fine form; *James Veitch*, warm rosy vermilion, extra fine; *M. Thibaut*, rich pale scarlet, fine form; *Beauté Suprême*, pale rose, bordered with white; *Ferdinand Kegeljan*, light orange red, densely spotted in the top petals, extra fine; *Eclatant*, intense dark reddish scarlet, extra fine; *Charmor (Bull)*, rich rosy pink, very fine indeed; *Antoinette Theliman*, rich double scarlet, extra fine; *Roi des Blancs*, an extra fine white; *Charles Albert*, a fine double white; *Frederick II.*, light orange scarlet, extra fine; *Unica*, intense rich glossy crimson; *Reine Marie Henriette*, pale pink, shaded and margined with white, richly spotted in the top petals; and several other fine sorts. A very fine unnamed seedling, double striped white, from M. Van Houtte, is a great advance. A large number of other very fine sorts were shown, such as *Belle Gautoise*, *Madame Camiart d'Hamale*, *Louis Napoleon*, *Cedo Nulli*, *Madame Ambroise Verschaffelt*, *Duc de Nassau*, *Rubens*, and a large number of other Continental and English raised varieties.

The pyramidal form of *Azaleas*, adopted by the English growers (as remarked in our last number), is altogether ignored here, and a more globular form is aimed at. In fact, it may be said that the half of a globe indicates the form of almost all the plants exhibited. The large number of plants exhibited gave, as already stated, a brilliant effect to the Exhibition.

Of the *Camellias* we cannot speak too highly, for almost all were wonderfully fine. The practice adopted here of grafting young plants on to old plants, literally placing young heads on old shoulders, has been the means of showing us the great results which arise from this practice. Symmetrically trained plants of a pyramidal form, close-growing from the bottom upwards, in luxuriant health, and covered with blossoms, were to be seen by the hundred. Many of these were monster specimens, but the freshness of health was everywhere visible. A large number of seedlings was shown, and in one group, exhibited by M. Camilla Van der Bosch, were two very fine things, viz.:—*Prince Royal*, of beautiful form, light pink colour, irregularly blotched with white, and *Eteudard de Flandre*, of exquisitely cupped form and substance, light veined pink, irregularly striped; this is a very beautiful variety. Amongst the best *Camellias* were *Frost's Perfection*, beautiful pinky bluish, shaded with white; *Charmante*, one of *Vervaeke's* seedlings, shaded pink, of fine form; *Comtesse de Flandre*, pale lilac, faintly streaked with pink, fine form; *Victoria Emmanuel II.*, bluish, striped with pink; *Angelo Cocchi*, much lighter than *Lavinia Maggi*; *Madame Ambroise Verschaffelt*, a very fine light striped kind; *Reine des Beantes*, beautiful shaded pink and bluish, fine form; *Leon Legmay*, *Leopold II.*, a superb rich dark crimson; *La Reine*, *Jeany Lind*, *Courtes of Orkney*, *Jubilee*, *Impératrice Eugénie*, *Mathotiana alba*, and many others. Nowhere else could such plants be brought together.

A greenhouse was devoted entirely to *Melocacti*, *Hyacinths*, and *Tulips*; of the former there were four excellent collections. Of *Hyacinths*, there was a very fine display. These were all grown in small pots, and although not equal in size of spike and growth to those exhibited by Mr. Cuttush, Mr. Paul, and others in London and Liverpool, they were a remarkable collection, and there were a large number of fine spikes. Some of the Haarlem cultivators exhibited collections of from 100 to 150 varieties, and all were very creditable.

These collections were very prettily arranged in banks on each side of the greenhouse and looked well. A collection of 125 *Hyacinths* grown in glasses elicited unbounded admiration. They had really been grown in the glasses, and each was a perfect specimen. The Jury evidently thought so, by awarding the first prize to those in glasses. Amongst these we noticed as especially fine—*Double Reds*: *Lord Wellington*, *Milton*, *Jeany Lind*, *Noble par Mérite*, and *Regina Victoria*. *Single Reds*: *La Dame du Lac*, *Agnes*, *Princess Clotilde*, *Dabatsch Sabalskauky*, *Von Schiller*, *Susanna Maria*, *Cavaignac*, *Mrs. Beecher Stowe*, *Josephine*, *Amphion*, and *Macaulay*. *Double Whites*: *La Tour d'Anvergne*, *Jeany Lind*, *Prince of Waterloo*, *Lord Anson*, and *Virgo*. *Single Whites*: *Pucelle d'Orleans*, *Roi Van Nederlanden*, *Hercules*, *La Candeur*, *Reine d'Hollande*, *Mont Blanc*, *Cleopatra*, *Alba Maxima*, *Madame Vanderhoof*, *Alba superbissima*, *Nina*, *Graudeur*, *Merveille*. *Double Blues*: *General Antenk*, *Garrick*, *Bloksberg*, *Van Speyk*, and *Laurens Koster*. *Single Blues*: *Leopold II.*, *Argus*, *Uncle Tom*, *Charles Dickens*, *Couronne de Cèle*, *Prince Albert*, *Nimrod*, *William I.*, *Grand Lillas*, and *Sir C. Napier*. We have named all these, as some may be glad to know what sorts do well in water, but the whole collection was good. So this proves that it is not necessary to have only certain sorts. One exhibitor sent sixteen pans of *Hyacinths*, each containing a dozen bulbs, and they had a very effective appearance. A very large number of new and little-known *Hyacinths* was exhibited. Amongst these were *Pima Donna*, not a new one, but most superbly coloured and grown; *Josephine*, rather thin but most brilliant in colour, rich orange and scarlet; *Goliath*, bluish striped with pale pink, and very showy; *Grand Duchess Olga*, a very pretty pale rosy pink, good spike—all *Reds*. In *Whites*: *Paganini*, *Teneriffe*, *Baroness Swaader*, *Die*, all fine; *Nectar*, a very fair creamy white with large finely-formed bell and close spike; *La Franchise* and *Miss Aiken*, fine. In *Blues*: *Zriny* is fine, dark velvety blue purple, fine close spike; *Emperor Alexander*, a peculiar shade of blue, fine bell and spike; *Julius Cesar*, shaded blue purple, fine close spike; *Prince Alexander*, a very fine dark purple; *Marie Antoinette*, fine; *Prince Bragation*, very fine and distinct; *Czar Peter*, *La Martine*, *Leontidas*, *Pleuveau*, *De Caudelle*, *Louis Philippe*, double; *Tollens* or *Prince of Wales*, *Arnold's Prince*, *Darwin*, *Tomb of Napoleon*, *King of the Blues*, and *Hereditary Prince of Sweden* were all very fine. There was not much new in *Yellows*. *Siberia* is a very fine creamy yellow, and *Lord Seymour* is also very fine, and *Lord Australia* is good. *Chateaubriand* is a very distinct yellow, and *Alphonse Karr* is a pale lemon colour and good. *Hyacinths* were shown in collections of 100 and 150. The display of *Tulips* was also good, and several new and little known kinds were shown. Among the most striking of these were *Leonardo da Vinci*, *La Cavaignac*, *Lac Van Haarlem*, *Rose d'Amour*, *Duc d'Angoulême*, *Duc de Bordeaux*, *Jeanne d'Arc*, *Marillo*, and *La Citrodelle*. In *Singles*: *Rosa Mundi*, *La Poitrin Blanche*, *Graude Blanche*, *Alba regalis*, *Duc de Wiemar*, *Grand Duc or Crown Imperial*, *Archiduc d'Autriche*, *Prince d'Autriche*, *Paul Morelles*, *Duchesse de Parma panache*, *Cramoisi pompre*, *Prince de Joinville*, *Mavrocordato*, and *Joost Van Vondel* are all very fine.

In a large building in the grounds, a quantity of *Rhododendrons* was displayed, and they formed huge banks of colour, but there was a great deficiency of those grand rich scarlets, crimsons, and fine whites which we see at the *Rhododendron* displays in London. *Empeur de Mexique*, conspicuously spotted alike in each petal, truss rather loose and not good in form, is a good variety to cross from. *Baronne Oxy* is another singularly-spotted light variety, not to be confounded with *Baron Oxy*, a heavily-spotted white variety. In this building were groups of hardy *Azaleas*, and what beautiful things they are in pots! forced hardy shrubs, hardy variegated plants in quantity, new *Conifers*, a collection of *Apples* and *Pears*, and a very interesting exhibition of various forms of grafting and budding.

Some forced fruits and vegetables were shown in another department. The *Grapes* were very poor. *Pine-apples* good. *Strawberries* in pots, only middling, and these appeared to have been potted shortly before forcing, for a pencil could easily be pushed to the bottom of the pot. *Chicory* seemed to be the most striking thing in forced vegetables. The *Peas* and *Beans* in pots could be beaten in hundreds of English gardens, and early *Potatoes* were nowhere compared with English growth.

They grow *Mignonette* well. Vigorous plants of the large-leaved kind—and in another mouth or so what plants they will be!—but only one plant in a pot. Then there were collections of *Violets*, hardy *Primulas* in species and varieties, *Cyclameus*, fancy *Pansies*, but very inferior to English raised kinds. Chinese *Primulas*, extremely poor in quality, and Variegated Zonal *Geraniums*, all English kinds, and badly coloured. These seem to be grown in a close house. I noticed a plant or two of *Lady Collum* in M. Ambroise Verschaffelt's nursery, which were beautifully coloured.

And now for the bouquets and groups of flowers for table decoration. The bouquets are enormously large generally, although I have at different times seen many beautiful medium-sized bouquets in the Brussels market, but all that were exhibited were very large—too large, I have always thought; but after seeing Her Majesty and the Comtesse de Flandre carrying bouquets of the same size, I begin to think we make them rather too small. There were several bridal bouquets, one of which was composed entirely of orange buds, not blossoms, each separately wired. The wires are very neatly covered

to resemble green moss, and the buds, although pretty close together are not crowded. I think sufficient fern is not used in constructing these bouquets. The groups of flowers for table (and some of them were very large), were too heavy and formal. The judicious introduction of more foliage and ferns would have relieved this and improved the arrangement. Head-dresses of flowers were exhibited, but were nothing remarkable. The White Persian Lilac and White Dentzia seemed to be valuable for this purpose.

Outside the building, scattered about the grounds, and here and there arranged in groups, were quite sufficient objects of interest to form an exhibition, and of some of these things we will give a brief sketch.

There were stands of garden implements and tools, containing many things which English amateurs and gardeners would hail with delight—pruning scissors and shears of all forms; knives, many of which would not delight us, being too clumsy and curved; garden chairs of every description, and so delightfully easy that a cigar and a snooze became first thoughts; many of these, made of light elastic iron tastefully painted, were more fit for a drawing-room; iron rods, to imitate stakes for Dahlias, standard Roses, &c. Then there were snug, inviting lawn tents, samples of wood latticework, screens for shading houses, or covering fruit trees; also boilers, one form of which I may as well say with Mr. Lane is "my idea" of their idea of a boiler. It is a capital application of a saddle boiler, and in one of your early numbers I will give you a rough sketch of it, and a few remarks. Meantime I would just remark that all the boilers exhibited were deficient in water space, most of them not having more than from 1 inch to 1½ inch clear water space, and corrosion would very soon reduce this. All the greenhouses are made of cast iron, and the arched roof seems to be the most popular. I believe we entertain an unjustifiable prejudice against them, and when speaking about the boiler, I shall worry you with "my idea" of iron houses and garden frames, of which samples were exhibited.

Standard Bays, Myrtles, Box, Orange trees, and all such things, in tubs, are greatly used in Belgium for terrace ornament. Many wonderful examples of these things were exhibited on this occasion. There was a pair of Sweet Bays on short stems, each 12 feet high and as much through, and a lot of others varying in smaller sizes. Then there was a pair of magnificent and bushy Orange trees, almost as large as the two Bays, standard Laurustinus, and a pair of Giant Clethra arborea on stems 7 feet high and 15 inches in circumference, each plant 18 feet high, with handsome heads; small-leaved Myrtles on stems, with heads 6 feet through; a magnificent lot of specimen Aloes, Variegated and other Yuccas; berried Aucubas, three of which were fully 5 feet high and 6 to 7 feet through, all amply testifying that berried Aucubas are grand things and *must* be generally planted.

A collection of standard Bays in pots, showing thirty different designs of twisted stems, indicated marvellous patience on the part of the grower, and formed a novel exhibition. The first thought which occurred to many was that such a process would so check the circulation of the sap as to produce sickly growth. Not so. These plants were very healthy. Two Cupressus Lawsoniana in tubs, each 20 feet high, and perfect pyramids, stood side by side with the monster Wellingtonias in tubs, quite as high. Samples of garden pots, statuary, wirework, and many other appliances for the garden met the eye in every direction. Nor must we omit to mention vines in pots, and a pair of wonderful plants of Phoradendron tenax, 5 to 6 feet high, and about 12 feet through.

Prizes were offered for fifty Conifers, and some extremely fine specimens were shown, many of them from 8 to 16 feet high, and in pots or tubs. M. Gangard and M. Auguste Van Geert both exhibited in this class. There were also two fine collections of thirty specimen Hollies in tubs and baskets. Specimens of various forms of training fruit trees were exhibited by M. Gangard and M. Van Houtte, but why the prize was awarded to the former I am at a loss to tell. Much more attention is devoted to the training and pruning of fruit trees in Belgium than by ourselves.

All that we have now to add is, that we all left Ghent delighted with our visit, and especially with the Exhibition, grateful to our friends there for the warmth of their reception, and all joining in the wish that we may meet there again in 1873.

ENTOMOLOGICAL SOCIETY.

THE second March meeting was held on the 16th of the month at Burlington House, the President, H. W. Bates, Esq., being in the chair. Amongst the new publications presented to the Society's library since the last meeting were Dr. Schaefuss's Memoir on the Scydmaenidae of South America; a new periodical work on the Coleoptera, by Baron Von Harold; and the Zeitung of the Stettin Entomological Society.

A curious Lepidopterous caterpillar from Brazil, forwarded by Dr. Peckholt, was exhibited by Mr. F. Smith. It lives in communities of considerable extent, and has the habit of forming nests as large as a man's head, of a strong woolly texture, in which it resides, upon trees. It has the body covered with long hairy bristles. It was not stated by Dr. Peckholt in what situation the chrysalis state is passed, or whether the caterpillar formed a cocoon within the nest, so that it was not

possible to determine whether it belonged to a diurnal species (butterfly), or to a nocturnal one (moth).

Mr. Stainton directed attention to a memoir by Dr. Hartmann, in which the natural history of three different species of Moths was recorded, belonging to the families Trochilidae (Trochilium cephaliformis), Tortricidae (Grapholitha interruptana, H. Schaff. duplicana, Zett.), and Tineidae (Gelechia sp.). These insects had all been reared from knots or galls on the stems of the common Juniper (Juniperus communis); and Mr. Stainton suggested that by a careful examination of the bushes of that tree in this country it might possibly be discovered that these insects were indigenous.

The President called attention to a general catalogue of Coleopterous insects classified according to Lacordaire's great work, by the Baron Von Harold, the publication of the commencement of which was announced.

Mr. Smith read an article from the "Guardian," a periodical of the last century, edited by Addison, giving an account, extracted from the "Proceedings" of the French Academy of 1713, of the economy of the common garden Ant, which the writer affirmed had the instinct to collect and store up grain for future supplies of food. A marvellous amount of detail was added of the proceedings of a colony introduced into a chamber, not only with reference to the fact of collecting and storing the food, but also of previously preparing it, and regularly airing it from time to time, all which statements Mr. Smith believed to be purely fictitious. Professor Westwood, however, considered that certain well-known facts in the economy of the Ant had been simply misunderstood and misrepresented by the writer. Thus, he believed that the grain stated to have been stored up was the cocoons of the pupae which the Ants often brought to the surface of the nests, and that this biting off the cap of the cocoon by the Ants for the escape of the enclosed insect on its arrival at the imago state had been mistaken for picking out the buds of the grains of Wheat to prevent them sprouting. Mr. Smith further remarked on the want of precision observable in the statements of facts of natural history by various French writers at the present day. Thus, M. Fabre's curious account of the economy of the bee parasites, Sitaris and Meloe, could not be relied upon, as he stated that the young larvae when hatched swam about in the fluid honey stored up in the wild bees' nests; whereas it was well known that these particular kinds of Bees only collect the pollen of flowers for the support of their own progeny.

PLANTS INHALING NOXIOUS GASES.

THE Editors' note at the foot of my article in page 234 reminded me very forcibly of an episode of my school days. A valued monitor, with a view of making a deserved castigation more effective, brought me to the front and administered it as publicly as possible. Still further, that the object of the correction should be lasting, he at the same time surprised me with what was then to me a valuable present. I have oftentimes thought since that this mode of assisting the memory was sound in principle. I am afraid that the castigation and this object of it would have been forgotten long ago but for the present. It is this which brings the whole scene vividly before me. I hope the slight rap on the knuckles which the Editore have been kind enough to bring me to the front to receive, will be supplemented with a present in the shape of the reasons why they "totally dissent" from the theory propounded of plants inhaling noxious gases. This information I shall hail with pleasure, and I believe it would also be acceptable to many others, who, like myself, are unable to lay hands on books which give the true theory of this and kindred subjects appertaining to the work in which we are engaged as the means of a livelihood. I make no pretensions to a knowledge of vegetable chemistry, or vegetable physiology. I rejoice in being a working gardener, rolling up my sleeves on a Monday morning, where they remain until my wife rolls them down again in the washtub; but while I work I think, often to no purpose I grant, and I hope still less to mislead. I am ambitious to the extent of being dissatisfied with an effect unless I can trace the cause. Nothing is to me such hard work as "guess work." To be able to give a reason for every thing I do is the goal at which I aim. I have been led into many difficulties, but never conquered one without finding the next more easy; and so I wade on, sometimes getting out of my depth, but hitherto I have safely reached the shore.

But why dabble in theory? it may be asked. Why not be satisfied with practice? I yield to no one in the estimation in which I hold practice, since it gives me good results; but much so-called practice is after all only false theory. I think there is much force in Horne Tooke's observation, "That he became all the better acquainted with the country through having the good luck sometimes to lose his way." I appear to have lost my way in my article above referred to; but I am in the country yet, and hope to know it the better of my pere-

grinations. The best instruction may often be gathered from mistakes, as the soundest wisdom is gathered from failure.

Since I may appear to have promulgated a theory recklessly and without due consideration, I may, perhaps, be permitted to give a brief *résumé* of my mode of reasoning, which led me to the conclusion which I had the boldness to submit to the public through the columns of the Journal. In respect to inhalation or absorption—for though the terms are different in animal, I have yet to learn that they are not synonymous in vegetable physiology, inasmuch as in the vegetable kingdom both are carried on by the same organs of respiration, while in animals inhalation is by the lungs, and absorption independent of them, except indirectly. Now, as to noxious or poisonous gases, my view is that excess is poison, and therefore noxious. As there is such a great analogy and harmony of operation between the vegetable and animal kingdoms, I think I am not unreasonable if I lay the latter under tribute for examples, and so reason by induction. Excess, then, is poison, both as taken into the system by liquid and solid constituents for its support, and also in the shape of vitiated air or noxious gas inhaled by respiration. In the former I will only instance the common mussel, and in the latter the extrication of a combination of gases, primarily carbonic acid, resultant from the burning of charcoal. A death resulting from either of these is death by poison, and in this case there must be something noxious. Neither is the immediate inhalation of noxious gas absolutely necessary to constitute animal poisoning. By the important functions of respiration the arterialisisation of the blood is effected. This function failing, then commences the work of poisoning by the penetration and circulation of venous blood acting on the nervous and muscular textures of the body, the venous blood itself being a poison of the most deadly kind. This poisoning takes place if the animal is placed *in vacuo*, or in an irrespirable gas, as nitrogen. Suffocation and asphyxia are the terms commonly applied when an animal dies from an excess of noxious gas; but it is in reality poisoned. Here, then, are my reasons for considering excess poison; and if the excess is in a gaseous form, it follows that it must be a noxious gas.

I will now step into the vegetable kingdom. Plants, I assume, possess organs of respiration, by which they inhale or absorb atmospheric constituents for assimilation and support. On the authority of the Editors plants would seem to possess a power of selection, and to apply only those elements which are essential to their welfare. This is new to me, and I do not for a moment hesitate to acknowledge and admit my ignorance. Here they possess an advantage over the animal kingdom. By what law this power of selection is effected and governed I am also ignorant. If by the law of compensation, I should have thought they would have the power to resist excess. This it appears, by that excellent work of reference "The Cottage Gardener's Dictionary," they are unable to do. According to that book, hotbeds sometimes have the air within them contaminated by carbonic acid, causing injury to the plants by an excess of acid which they are not able to digest. "Digest" would imply pre-absorption; if so, it seems to me that they absorb an excess which injures them, which excess of gas is consequently noxious.

During the past summer a gentleman, a few miles from here, in order to destroy the red spider had a quantity of sulphur burned in his greenhouse. This not only killed the red spider but also every plant in the house, and every leaf of the Vines also. My opinion, and I submit it was a natural one, and it was endorsed by able men than myself, was that death here resulted from an excess of sulphurous acid absorbed by the leaves. This appears to be erroneous. Strictly speaking the Vines may be said to have been suffocated, and have died from want of gases which they could not absorb, or by the retention of gases which they could not transpire or liberate. What is this but poisoning by gases previously absorbed becoming noxious, just on the principle of venous blood in the animal becoming poison from not being arterialisised? If a plant like an animal is placed in irrespirable gas, I submit it is to all intents and purposes poisoned by its own constituents previously absorbed by its roots and leaves, and that part of it which is gaseous becoming noxious gas.

I will refrain from entering further into this, as I think I have said enough to make it understood what I meant in my previous article. There I may have wrongly expressed myself, but the results are the same, and are for all practical purposes applicable to the case. In this article I may but have made a still greater parade of my ignorance, and my temerity may be answered by another rap on the knuckles, or, perhaps

this time by the bastinado. Well, be it so; I will try and submit to it peacefully, since I know it will be inflicted mercifully. Feeling that this is a subject not exactly of a kind suited to your columns, I am unwilling to put pressure on space which might be devoted to more practical and matter-of-fact subjects; I shall therefore try and not be tempted to enter further into the matter.—J. W.

[We should, under any circumstances, readily admit our excellent correspondent's explanation; but we do so the more readily because his explanation shows where he was wrong, and why we said we differed from him. He assumed, and still assumes, that suffocation is the same as poisoning. If so, the man who is hung is poisoned! Now, unquestionably, this similarity is not admitted. Suffocation is the exclusion of the gas needful for a plant's or animal's life. Poisoning, on the other hand, is the actual admission of something, whether by root, leaf, or mouth, injurious or fatal to the plant or animal. If a plant is plunged into an atmosphere containing a great excess of either carbonic acid or sulphurous acid, arising from burning sulphur, it is killed by suffocation. It does not inhale either of the gases, and in the case of the sulphurous acid the very texture of the leaves' epidermis is destroyed. The same power of rejection is possessed by the spongioles of the rootlets. It has been shown by actual experiment, that when two or three salts were dissolved in one water and the roots of a plant placed in it, they absorbed one or two of the salts and totally rejected the other. That leaves have the power of selecting the gas or gases beneficial to the plant, has this evidence: M. Saussure grew the Lesser Periwinkle (*Vinca minor*), in a vessel containing, in round numbers, 212 parts azote, 56 parts oxygen, and 22 carbonic acid. The plant absorbed all the carbonic acid, but did not diminish the other two gases.

What is said in the "Cottage Gardener's Dictionary" is in no way contradictory of our opinion. The carbonic acid may be to a certain extent increased beyond the proportion usually present in the atmosphere, and yet be inhaled by the plant, and even with apparent benefit for awhile; but it is injurious if long continued. So in the case of man; he can breathe an atmosphere containing an excess of oxygen. It increases the rapidity of his pulse, intensifies the colour in his cheeks, but hurried respiration, debility, and insensibility soon occur.—*Eds.*]

DOUBLE-BLOSSOMED PEACH FRUITFUL.

I HAVE sent to-day a branch of the double-blossomed Peach for your inspection. We have here a fine standard of it now in beauty, but I have not sent it for its flowering properties so much as its fruiting. Last season I gathered six dozen of Peaches from it all ripe, and several dishes were sent to my employer's table, and pronounced very good.

The tree stands in quite an open situation, but, notwithstanding that, it stood the last frost in May, while others on a south wall lost nearly all their fruit. As I do not think this a common occurrence I thought it might be worthy of notice.—*E. CHITTY, Catlands Park, Waltham-on-Thames.*

Although more numerous petalled than is usual in a Peach blossom, yet each flower of the specimen sent has perfect stamens and pistil. We once had in Essex a maiden seedling standard Peach tree, and it bore fruit for several years.]

PROPAGATION OF CENTAUREA CANDIDISSIMA.

Any one without difficulty may secure a stock to propagate from, by taking up in autumn as many plants as will be required for cuttings, and treating them in the following manner: Lift the plants by the end of October or early in November, pick off the dead leaves, and pot in soil consisting of about equal parts of loam and dung from an old Mushroom bed or hotbed, with a little sand. Then water them, place them in a lateinery or Peach house, and through the winter treat like Scarlet Pelargoniums.

About the middle of January place them in a warmer situation to produce growth for propagation. As soon as they are growing freely pick out the tops; they will then push numerous side shoots, which will be fit for cuttings by the beginning of March—quite soon enough to begin; and if the following directions be adhered to no difficulty will be met with in obtaining by the end of May a fine stock of plants for bedding-out or for pot culture.

Into saucers such as are in use in most gardens put about

three-quarters of an inch of clean sand, pour warm water on it, stir up and give it a shake, and drain off the water till the sand is firm enough for the cuttings to stand in. Next pull the cuttings off the plants, not cut them off, and stick them in the sand, the largest in the centre. The saucers I use are 4 and 5 inches in diameter, and hold from twelve to sixteen cuttings. Plunge them to the rim in a hotbed or propagating case, where the bottom heat is from 70 to 80, and the cuttings will be fit to pot-off in ten or twelve days. They should then be potted into 2-inch pots. Mix equal parts of rotten dung and loam with a little sand, riddle it through a half-inch sieve, and use the largest for drainage and the fine for potting with. Keep the young plants in a warm house till the roots show at the bottom of the pots; they will then be fit to shift into 4 or 5-inch pots, using the same kind of soil. Kept in a cool place, such as an orchard or Peach house, they will be fine plants for bedding-out by May.

A few plants grown in larger pots will form fine subjects for decoration in-doors, and cuttings afterwards. The cuttings will not want watering during the time they are striking; merely sprinkle them through a fine rose in favourable days.

In turning out the plants, strike the edge of the saucer on the potting bench to loosen the sand, so as not to break the roots.

Not one cutting out of fifty will fail to strike root by this method. I am aware that striking cuttings in sand and water is not new, having been fully described by Mr. Beaton four or five years since as practised extensively by Mr. Kidd, of Bushy Park.—J. T. CUREN, *Gardener to F. Swarwick, Esq., Whittington House, Chester* told.

SNAKES AND ADDERS.

CAN any of your readers inform me whether there is any means, by poison or otherwise, of destroying or driving away snakes, and especially vipers? My garden is infested with both; and it is scarcely possible, owing to the vicinity of a pond and shrubberies, with stony ground and thick underwood, to clear their haunts.—H. R.

[We are not able from our own experience to advise you as we would wish, but were we so situated we would poison some frogs and strips of fresh meat, and lay them carelessly and liberally in the haunts of the vipers and snakes. We recollect of a case, but not so bad as yours, and where, also, there was a small piece of water, about which and the lawn close to it they became a dangerous nuisance. In spring a few heaps of stones were thrown together, leaving open interstices between them, in which moss was lightly placed. As expected, the snakes made these heaps their home, and when they became pretty well colonised, a fire of brushwood, with sulphur sprinkled on the wood, was placed round them, and hundreds were thus destroyed. We shall be glad if some correspondent will give better information and advice.]

EMIGRATING.

YOUR correspondent, "W. T. G." (see page 201), draws a very dismal picture for intending emigrants to the British North American colonies and the United States, a picture enough to deter the most stout-hearted of the ill-paid English gardeners from attempting to better their condition by emigrating to that country.

Without disputing anything "W. T. G." has said, I wish to draw the attention of intending emigrants (of course I mean my brother horticulturists and farmers), to a British colony, where the cultivator of the soil will find very few of the long list of drawbacks detailed by "W. T. G.," I mean Queensland, one of the Australian colonies. There the emigrant need not fear the uprooting of his vines and fruit trees in winter, as frosts are unknown in that favoured country. The climate very much resembles that favourite resort of our invalids, Madeira, being only a few degrees warmer in summer and a few degrees colder in winter. The soil and climate are admirably adapted for the growth of all tropical and subtropical plants. The following is an extract from a book written on Queensland by the Rev. Mr. Wight in 1861: "On the same farm you may see growing Maize, Peas, Potatoes, Oats, Coffee, Sugar Cane, Arrowroot, Ginger, Flax, Cotton, Peaches, Oranges, Apricots, Figs, Mulberries, Grape Vines, Pine Apples, and Bananas. All these may be seen growing to perfection in the open air, and under ordinary treatment in the neighbourhood

of Brisbane. Land is cheap; you can have your pick of the agricultural reserves for £1 an acre."

After what I have said, I need only say that I would advise all cultivators of the soil, that think of emigrating, to go to Queensland. I may add that the colony is rich in minerals, and gold is found abundantly in the northern parts. J.

The only comment we shall offer are the following lines, written by an emigrant:—

"Come, boys, I have something to tell you;
Come near, I would whisper it low—
You are thinking of leaving the homestead
Don't be in a hurry to go!
"You talk of the mines of Australia—
They're wealthy in gold without doubt;
But, ah! there is gold in the soil, boys,
If only you'll shovel it out.
The mere outside trade is a hazard,
The goods are first high and then low;
Better dig the old soil a while longer
Don't be in a hurry to go!
"The great busy West has inducements,
And so has the busiest East;
But wealth is not made in a day, boys—
Don't be in a hurry to start;
The bankers and brokers are wealthy,
They take in their thousands or so—
Ah! think of the frauds and deceptions—
Don't be in a hurry to go!
"Home soil is the safest and surest,
The orchards are loaded to-day,
You're as free as the air of the mountains,
And monarch of all you survey.
Better stay on that soil a while longer,
Though profits come in rather slow;
Remember, you've nothing to risk, boys—
Don't be in a hurry to go!"

A WORD FOR AMARYLLIS CULTURE.

AMONGST plants really worthy of cultivation there are very few more deserving of patronage than the Amaryllis family; occasionally we see a solitary plant in flower, but we hardly ever find these plants grown in quantity, or in proportion to others. We see in collections dozens of Azaleas, Pelargoniums, and kindred plants, but seldom a fair proportion of Amaryllises. I often regret that this omission should be so general, because wherever a good collection is kept, and well bloomed and judiciously mixed with other conservatory plants, the Amaryllises contribute a peculiar stateliness and diversity which enhance the beauty of the collection.

It is not, however, in the spring solely, that plants of this charming family develop their beauties, for they can be had in bloom all the year round, by a little adjustment of rest and action. I need hardly say that if they are fit associates for Azaleas, and are undimmed by the dazzling brilliancy of these, their presence must be always welcome.

In point of colour there is a wide field for selection. From *Reticulata rosea*, a chaste white, most delicately pencilled with faint rose, we may select still higher and brighter colours in the *Vittata* and *Marginata venusta* section, white and scarlet. From these we may pass on through the *Johnsoni* section, and find ourselves in company with the self-coloured ones. Amongst these may be found a brilliant and most beautiful array of colour, from orange to the darkest maroon. Some of them are most deliciously sweet, quite equal to any flower in cultivation in point of aromatic perfume.

When a very fine display is desired, from two to six bulbs should be planted in one pot. If the bulbs are equal in point of size, and have been grown and rested similarly, then when started into growth, most probably every bulb will send up a flower spathe, and very often two spikes to each bulb will be the result. We have often produced ten spikes in one pot, with from four to seven blooms on each, and when such a display is secured and well developed, there is hardly a plant of any description that can surpass the Amaryllis. For large conservatories, and for contrast with Azaleas, I can recommend specimen Amaryllises. Like other plants, their rest can only be estimated when seen as above grown. They are, nevertheless, very effective in single bulbs.

I find it a good plan in practice to treat them liberally. When potting I give good shafts with plenty of drainage, and use turfy loam and leaf soil in equal proportions, with a small mixture of peat and sand. They should be started in heat, when in bloom placed in a cooler atmosphere, and when out of bloom they should have more heat, and exposure to sunshine, gradually withholding water as the plant completes its growth. It should then be allowed to go gradually to rest, removing the

foliage only when it withers. By adopting this plan bloom is secured to a certainty, and the bulbs do not degenerate under such treatment. I have bulbs now which have bloomed here for sixteen years. I commenced with about a dozen different varieties, fertilised them, and raised hundreds of seedlings. I like the old *Aulica* for this purpose, and think that the seedlings from it are particularly strongly constituted—so much so, that they will grow and bloom in an ordinary greenhouse. Their defect consists in a tendency to produce but two blooms like the parent, while it is most desirable to secure those capable of bearing a larger number of blooms on a spike. It takes three or four years to make blooming bulbs from seed.—WILLIAM PAYNE, *Fir Vale, Sheffield.*

FLOWERS TOO MUCH NEGLECTED.

I CANNOT refrain from noticing a few that deserve a little more attention than they are receiving. What can be more attractive at this season than pyramids 6 or 8 feet high of *Ribes sanguineum* and *sanguineum album*, clothed from bottom to top in their distinct colours? or they may be grown not as pyramids, but as bushes. Then, what splendid pillar plants are the two varieties of *Cydonia japonica*, the one white the other scarlet, almost too bright for the eye to rest upon in the full sunshine, such as we have been enjoying of late. They are likewise suitable for training against a wall or fence. Let us next look at those fine old sorts of double Wallflowers, of various colours, but the bright yellow outshines them all. What can be more pleasing than a bed or edging of *Erythronium dens-canis* with its white and purple flowers and its spotted leaves? and bright-coloured *Hepatica triloba*, single and double, of various hues? There is also *Bellis aeneuifolia*, an acquisition either in-doors or out. Another of our little stars that is creeping into favour is *Aubrietia deltoidea variegata*; for either rock-work, edging, or patchwork, it deserves a place in every collection. Last, but not least, let us admire *Saxifraga oppositifolia*, with alba and major in contrast. They are really gems of the first water when taken care of, forming splendid edgings, or, shall I say, carpets of pink and white blossoms, well repaying any amount of care bestowed upon them.

LIST OF PLANTS IN BLOOM.

March 2. <i>Crocus vernus</i> (blue, white, striped, and purple).	March 18. <i>Acer rubrum</i>
Cloth of Gold	<i>Alnus glutinosa laciniata</i>
<i>Ulmus montana campestris</i>	20. <i>Berberis empetrifolia</i>
<i>Populus tremula</i>	<i>Comptonia asplenifolia</i>
6. <i>Aubrietia deltoidea</i>	<i>Kerria japonica</i>
<i>Ribes sanguineum</i>	<i>Polyanthus Fire King</i>
<i>Viola odorata plena</i>	<i>Populus alba argentea canescens</i>
<i>Primula vulgaris</i>	<i>Salix helix</i>
<i>Erythronium dens-canis</i>	<i>Lambertiana prinoides triandra</i>
<i>Pulmonaria officinalis</i>	<i>Vinca major minor</i>
10. <i>Apricots</i>	24. <i>Hyacinthus orientalis botryoides</i>
<i>Veronica hederifolia</i>	<i>Narcissus pseudo-narcissus biflorus odoratus</i>
<i>Anemone hortensis</i>	<i>Van Thol Tulips</i>
<i>Tussilago farfara</i>	<i>Primula cortusoides vulgaris</i> , varieties
<i>Asarum europæum</i>	Daisies
<i>Aubrietia deltoidea variegata</i>	28. <i>Amygdalus communis dulcis incana</i>
<i>Malcolmia maritima</i>	Wallflower, double yellow, dark crimson
16. <i>Larix europæa</i>	30. <i>Berberis aquifolium</i>
<i>Prunus spinosa</i>	<i>Peaches</i>
<i>Potentilla fragaria</i>	<i>Nectarines</i>
<i>Cydonia japonica alba</i>	<i>Plums</i>
<i>Pulmonaria pinnatifida</i>	<i>Pears</i>
18. <i>Ruscus aculeatus</i>	<i>Cherries</i>
<i>Buxus sempervirens</i>	<i>Picaria ranunculoides alba</i>
<i>Anemone nemorosa plena</i>	
<i>Gentiana acandis</i>	
<i>Corydalis bulbosa</i>	
<i>Saxifraga oppositifolia alba major</i>	
<i>Scilla bifida</i>	
<i>Tussilago alpina</i>	
<i>Viola odorata plena canina alba</i>	
<i>Acer dasycarpum</i>	

—M. H., *Acklam Hall, Middlesbrough-on-Tees.*

SCALE DESTROYED BY PARAFFIN OIL.

I HAVE been trying experiments on the best way of destroying scale, using a great many different applications with various results; but a short time ago I met with something by accident which I do not think has been tried before. I have a large

Fern case heated by hot water, and I use a paraffin lamp under the boiler. After filling the lamp one morning I happened to find a scale on a Fern frond, and in taking him off I used my finger which had come in contact with the oil; he came off much quicker than usual, and it immediately struck me that the oil had something to do with it. I therefore took some oil, and going into one of the hothouses used it on a young Orange tree with scale on it. The scale all came off with the slightest touch of paraffin, and the plant does not look any the worse of the oil. I am going to try it on one or two Ferns. Our gardener says that he never saw scale come off so quickly. I think I will try the vapour from paraffin on some young Ferns when I can find any with scale on them.—THOMAS CLAY.

[We shall be obliged by a statement of the results of your experiments.]

BAG-HOLDER AND TUNNEL COMBINED.

THE engraving represents the simplest, most convenient, and altogether the best arrangement for holding bags while filling with grain, meal, or anything else put into bags. It consists of

a metallic tunnel, to which are attached four steel hooks, which hold the mouth of the bag distended in such form as readily to receive the grain from the measure or shovel without the inconvenience of filling the bag alone.—(*Prairie Farmer.*)

GREEN FLY ON FRUIT TREES IN BLOOM.

Our orchard-house Peach and Nectarine trees have been, and still continue to be, much infested with green fly, and the insects, in spite of all that we have been able to do to destroy them, seem to be as numerous as ever. Having already destroyed nearly all the blossoms, they now seem to threaten the young shoots with the same fate.

We have an old viney 40 feet long by 15 wide, and the Vines being worthless, we cleared them away. The idea of experimenting with a few orchard-house trees having occurred to us, we commenced with ten Peach and Nectarine trees, and by following up Mr. Pearson's directions as closely as our circumstances would permit, we succeeded in ripening a tolerably fair crop of fruit last year, which circumstance induced my employer to increase the number this year to thirty-two, including Apricot, Plum, Cherry, Apple, and Pear trees.

The trees which fruited with us last year ripened their wood well, and having been carefully stopped, were in point of appearance all that we could desire in respect to fruit and wood buds; indeed, a month ago they looked the very picture of health, but within the last three weeks the green fly attacked them, and by its ravages has given us great uneasiness, and caused us to entertain grave doubts as to whether it is possible to keep Peach trees free from green fly under certain circumstances. Mr. Pearson says, "The green smother fly must be got

rid of;" but how, is another story. We have not a house on the place that is anything like smoke-tight, so with us fumigating is almost out of the question. Syringing with tobacco water or quassia mixture is impracticable with trees in full bloom. Brushing off the aphides with camel-hair brushes dipped in tobacco water has been carefully resorted to by the young ladies with the most praiseworthy perseverance, but as fast as the trees are cleaned they become covered again, and as a last resort I write to you for advice, as we are at our wits' end. Our Apricot trees, which are arranged amongst the infected Peach trees, are all right, being well sprinkled with fruit; the Cherry and Pear trees are also looking well. The green fly has attacked some of the Plums, and something not unlike mildew has appeared on the Apples. Now, we want to know whether it is possible in our case to ward off the attacks of green fly by previous manumgement, without being obliged to have recourse to much fumigating and such like doctoring whilst the trees are in bloom? because if orchard-house trees are so very liable to be so terribly injured, and the means of prevention so difficult, our hopes of success will be as much impaired as the health of the trees by the blight.—DILEMMA.

[We have known cases quite as bad followed by great success. There is nothing in the house to prevent your being quite successful. One thing you seem to have omitted, and that is washing the trees in autumn and winter; this should always be done in the way of preventive. Most likely if with a brush you had washed the trees with warm soap water, or syringed them well, and then painted them with weak Gishurst, or even with a paint of sulphur, clay, lime, and soot, so thin as to work freely, you would not have been so troubled, though you might have had some green fly. This season we drew merely a little limewash over our trees, and we have not noticed insects as yet on more than half a dozen shoots, but we have had them years ago in abundance. With the trees in bloom, and the insects so clustering round the bloom, you can do little good with washing or brushing.]

The openness of the house is not favourable for fumigating, but not so much so as to prevent that proceeding being successful if you cover the roof with cloth or mats, and keep them wet. We have smoked such open-glazed houses with the aid of the garden engine alone, playing on the roof all the time, and the water thus filling the spaces of the laps. If for want of cloths you could lay hands on some rough hay or straw in a mild day to cover the roof, and use the water engine freely, you will find the smoking very effectual, but you must not give it too strong. The roof should be slightly shaded for a few days, and then the smoking should be repeated, and after that we should hope that syringing would keep all right. After the second smoking you had better shade a little for a few days.

The simplest mode for temporarily shading would be to scrape down the size of a walnut of fine whitening into three or four gallons of water, and then with a syringe throw it nicely over the roof; the first shower will wash it all off, and then shading will not be needed. Of course it will not be needed in dull weather; but in such weather as preceded the 4th of April it would be wanted, otherwise the blossoms would suffer. We say again, "Never give up," you will yet succeed to your own satisfaction. See "Doings of the Week."

NOTES AND GLEANINGS.

With the view of assisting the EDUCATION OF YOUNG GARDENERS, the Council of the ROYAL HORTICULTURAL SOCIETY have made arrangements through the Department of Science and Art for the formation of a Drawing Class at Chiswick. Until the class becomes too large for the room available, the lessons will be given in the Garden of the Society on the Wednesday evening of each week, excepting in August and September, between the hours of seven and nine o'clock. Arrangements have also been made for giving a course of twenty lessons in Surveying, on evenings, of which due notice will hereafter be given.

The fees for the Chiswick students will be paid by the Society, and also the cost of all models and examples for instruction, but the students will have to provide their own drawing materials. A limited number of other young gardeners, well recommended by their employers, will be admitted to these classes on a payment of a fee of 5s. per subject for a session of twenty lessons; they will also have to provide their own drawing materials.

The subjects of instruction will be—Free-hand Drawing,

Model Drawing and Sketching from objects, Geometrical Drawing, and Elementary Design as applicable to Landscape Gardening; Land-measuring, including levelling.

The Drawing class will commence its work on Wednesday, April 8th; the Surveying class in May. All applications for admission to the classes are to be made to Mr. James Richards, the Assistant Secretary of the Society.

—We are authorised to announce that the Council of the Royal Horticultural Society have decided on offering for sale by auction the splendid collection of twelve varieties of NEW HYBRID COLEUS, raised in the Society's garden at Chiswick, and that the sale will take place at the rooms of Mr. J. C. Stevens, King Street, Covent Garden, on Wednesday, the 22nd inst. We cannot commend too highly this step, which will permit these beautiful plants to be at once put in trade, and will enable the public generally to participate in the possession and enjoyment of a set of the finest decorative plants which have been introduced of late years.

—On Thursday last, the 2nd of April, Her Majesty, accompanied by Princess Christian and Prince Leopold, visited Mr. WILLIAM PAUL'S SPRING SNOW at the Royal Horticultural Gardens; and on inspecting the flowers, Her Majesty was graciously pleased to express her gratification, and requested to be furnished with copies of Mr. Paul's works on horticulture, which were at once supplied.

—THEIR ROYAL HIGHNESSES the Duchess of Cambridge and the Princess Mary of Teck honoured Messrs. Veitch & Sons by visiting the Royal Exotic Nurseries, Chelsea, on the 1st inst., and spent considerable time in inspecting the plants, &c.

—We are glad to see in our advertising columns that the inquiry of "L. M. N." has aroused attention to the query, "Where are FLOWER POTS to be had?" Knowing that so much importance attaches to the quality of the pottery used, Mr. Collier has for some years been unsparing of expense and labour, both in the selection of suitable material for and in manufacturing garden pottery.

—THE Twenty-fifth Anniversary Dinner of the GARDENERS' ROYAL BENEVOLENT INSTITUTION has been fixed for the 24th of June, and M. T. Bass, Esq., M.P., will preside upon the occasion.

—ON the 28th of March, at Brighton, in the eighty-eighth year of his life, died EDWARD JESSE. Gardeners and naturalists are the children of age, and truly marked as those "long walking hand-in-hand with time." He had retired from public life about five years since, but retained his characteristic blithe and candid spirit to the last. The following biographical notice is extracted from "Men of the Time."

"EDWARD JESSE, son of the late Rev. William Jesse, Vicar of Hutton Cranswick, Yorkshire, and subsequently of Bewdley, Worcestershire, was born at the former place in January, 1780. He was educated privately, and at eighteen years of age entered the public service as a clerk in the St. Domingo office. He next became private secretary to Lord Dartmouth, while President of the Board of Control, and when that nobleman became Lord Steward of the Household, he obtained for Mr. Jesse the court office of Gentleman of the Ewry. Mr. Jesse subsequently became Controller of the copper coinage issued by Messrs. Boulton & Watt at Birmingham. About the year 1812 he was appointed a Commissioner of Hackney Coaches, and soon afterwards Deputy Surveyor General of the Royal Parks and Palaces. This post he held, together with his office at Court, until 1830, when both offices were abolished, and he retired on a pension. Mr. Jesse is the author of 'Favourite Plants and Rural Studies,' 'Gleanings in Natural History,' 'Anecdotes of Dogs,' and editions with notes of 'Izaak Walton's Angler,' and of 'White's Selborne,' published in one of Mr. Bohn's series in 1819; an edition, much enlarged, of Ritchie's 'Windsor Castle,' 'Lectures on Natural History,' &c. His eldest daughter, Mrs. Houstoun, is the author of 'Hesperos, or Travels in the West,' a work most favourably noticed by Lockhart; 'Texas and the Gulf of Mexico;' and also of some novels, including 'Recommended to Mercy,' 'Such Things Are,' &c.

Mr. Jesse's son, John Heneage Jesse, is favourably known as the author of several historical and biographical works.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Broccoli, all the varieties require a deep rich soil, and the ground should be trenched to the depth of at least 2 feet, incorpo-

rating with it as the work proceeds abundance of rich manure. The early varieties, such as the Purple Cape, Grange's White Cape, Walcheren, &c., should be sown from the middle of this month to the middle of May, according to locality; and a second sowing of similar kinds should be made about a fortnight after the first. These will succeed the Cauliflowers, and will carry the supply on to Christmas. Two or three sowings of Snow's Winter White put in from the beginning of April to the middle of May will keep up the supply until the Sprouting varieties are ready, and these again till the spring kinds come in. *Carrots*, sow now the Covent Garden Long Surrey, the longest and best for a main crop. Sow in drills 12 or 15 inches apart, covering the seeds evenly to the depth of about half an inch. *Cucumbers* (Ridge), sow now in pots or pans filled with light soil, covering the seeds about half an inch, and set in a Cucumber frame or any other place where a moist gentle heat is maintained. As soon as the plants have made their seed leaves, and before they become drawn, shift them into 5-inch pots, putting two plants in each, and replace them in a warm moist situation. To keep the plants dwarf and stocky place them near the glass, and when they are established and moderately strong gradually admit the air more freely, and endeavour to have them well prepared for planting-out by the middle or end of May. *Lettuce*, sow for successional crops in beds of well-pulverised soil at intervals of about a fortnight until the end of July. *Saroy's*, a succession may now be sown. *Turnips*, sow a small breadth of the American Strap-leaf, a sort superior in flavour and quick in growth.

FRUIT GARDEN.

Newly planted trees will require to be well watered in this dry weather, and afterwards mulched. Both Peach and Apricot trees will now require partial disbudding, removing only a few shoots at a time, that the flow of sap may not be checked. Pick out the points of strong shoots, which will ensure healthy bearing wood.

FLOWER GARDEN.

The necessity of strict attention to the watering of newly planted trees and shrubs cannot be too much insisted upon; and the watering should not be a mere wetting of the surface of the soil, but a thorough drenching to the depth of a foot or 18 inches. Proceed with the hoeing and raking of borders, and throw a little Mignonette or Sweet Alyssum seed in all bare places. The time will not be uselessly spent in eradicating Plantain and other broad-leaved weeds from the lawn. Attend to mowing and sweeping, and keep every part of the garden clean and neat. In mowing the American garden mulch the beds with short grass; this not only prevents the parching-up of the soil, but the grass, when decayed, is an excellent manure for the plants. Put in the seeds of biennials as soon as possible, sowing them in drills 9 inches or a foot apart, and covering them with rich soil. Stocks, &c., in the seed beds are now becoming crowded, therefore take advantage of the first shower to transplant them. Some of the earlier kinds of Tulips are putting up their buds. This is a critical period, for heavy rains are often succeeded by frosts, which congeal the water retained by the leaves, and consequently the future blooms are surrounded by a mass of ice to their certain injury. Some florists draw out the water with a syringe, others on hands and knees make the circuit of their beds, blowing it out with their mouths. Whatever means, however, may be adopted, the moisture must be removed. Pinks are on the move, and must be attended to; these when planted in the spring seldom lace well.

GREENHOUSE AND CONSERVATORY.

Where the supply of plants in the conservatory is limited, you must make the best of their bloom by slightly shading them in fine days, although doing so is not good for young growths. Have cuttings of *Pelargonium Album multiflorum* put in now for flowering next November. *Fulgoria* is the best of all the late Roses for flowering in November and December; it continues in bloom till the forced ones come in. Now is the time to obtain a reserve stock of *Heliotropes* for forcing next winter. It is also a good time to put in cuttings of *Plectotes* for forcing after Christmas. If you wish to have a good stock of the plants named you must prepare always six months in advance. The increased heat of the greenhouse is not intended to be by fire heat, but by giving less air, and shutting up the house early in the afternoon, when a moderate use of the syringe may safely be practised. Every plant that is intended for a specimen should have the best place in the house, and should be turned round twice or thrice a-week; the shoots should be stopped from time to time, and it should have free-

dom on all sides. Epacris and early spring Heaths will bear close-pruning after they have done flowering. Correas that have been flowering should now be rather closely pruned and kept in-doors all summer, when they will take the place of Fuchsias after September. *Luculias* that have been at rest since flowering are now beginning to grow again, and should be kept in a low moist atmosphere till all the eyes break forth. Forcing the *Luculia* at this stage, or even encouraging it to make an early growth, was the principal cause of its failure on its first introduction.

STOVE.

Now that the plants are taking hold of the fresh soil more air may be allowed them, but shut up early in the afternoon, and when the watering is finished give them a good syringing overhead. Be sparing of fire heat after this time, even although the thermometer is down to 55° in the morning. The fine weather we have experienced, hot dry days and cool mornings, ought to teach us how to regulate the temperature for our house plants. The last portion of the *Gesneras* and *Acimenes* should now be potted, as they can hardly be safe any longer in their dry state; but to have them late in September and October they must be kept back till about the end of May in a cold pit, allowing them no more water than will keep the soil from being quite dry. There is more merit in retarding plants properly than there is in forcing them into early bloom.

FORCING PIT.

Hedychiums to flower late in the summer may now be started, and another batch of *Tuberoses* put in for succession. *Primula sinensis* for flowering from September should now be little stocky plants fit to be placed out in cold close frames by the middle of May, and more seeds of it should now be sown. *Gesnera zebrina* and *longifolia*, both tall flowers, should now be pushed on by all the heat and moisture at command.

PITS AND FRAMES.

The most forward of the *Hydrangeas* now in bloom must be hardened off preparatory to being bedded-out; and Stocks and other plants blooming in pots may now be removed to the flower garden, taking care to have mats at hand to cover them in case of severe frost. Most of the plants for bedding-out may now be removed to temporary pits, or placed in sheltered situations; and if the pots are wanted a number of the more hardy may be plunged in light sandy soil. Now is a good time to divide the stools of *Chrysanthemums*, and cuttings should be put in of those that are scarce.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Such a week of scorching days and clear cold frosty nights. The lawns and pastures have scarcely made any progress for ten days. In the belief that changes were approaching, opportunity was taken of the open dry weather to forward some kinds of work.

First of all, a regular hoeing and stirring was given among all young growing crops; Cauliflowers and forward Cabbages were assisted with some manure water, and, the former especially, mulched with rotten dung. Peas were sown and Broad Beans planted, and Lettuces hardened-off for planting, as when very small they are so apt to be carried off by the birds. Potatoes were planted to succeed those in frames and earth beds. Spinach was sown for succession. *Dwarf Kidney Beans* were sown in pots to be partly transferred to other pots, and a few to a sheltered place in a few weeks, as at the foot of a wall. What with damp and vermin we did not save a seed last season, and good seed of many sorts is scarce this season. For general cropping in-doors and out we prefer the China Dwarf, or the Robin's Egg; but we must do without it this season. The creams and the yellows produce fine pods. There is a prejudice against those whose pods are mottled and speckled; but we never found anything the matter with the flavour of them. The Newington Wonder is very good when the small pods are gathered young and cooked whole. Sowed Scarlet Runners in some leaf mould, where they can have protection. The ground being dry, rolled that on which Onions and Carrots had been sown, so as to give a firm surface. A skiff on the surface with a Dutch hoe when the seedlings are all up will prevent cracking and gaping in our stiff soil.

Pricked-out, or rather planted, a bed of Celery under glass that had been previously pricked-out. This will come in early when transplanted into trenches. Would have pricked-out lots of Celery, Cauliflower, Cabbage, &c.; but the weather was very

favourable for out-door work, and much of such pricking-off work can be done in a dull or wet day. By so contriving, a wet day is generally one of our busiest days. Sowed a portion of our Winter Greens—Borecoles, Savoy, Brussels Sprouts, and Broccolis, and will sow the rest in a fortnight or so. The ground, rather rough, was broken, rolled, and raked, the seeds sown, and the surface beaten with a spade, then, as the weather was dry, slightly watered through a rose, and shortly afterwards covered with a sprinkling of riddled fine soil from under the potting benches, and at once netted to keep the birds away. In this way all the refuse from pot plants comes in useful for such general purposes. Being dry it does also for mixing with stronger soil for Potatoes in frames, &c. It is of much importance to have a quantity of dry soil to go to in winter and spring.

The weather being so bright, most of the crops under the protection of glass, as Radishes, Lettuces, Potatoes, &c., wanted watering; and we would have preferred to have given them water a little warmed instead of at the natural temperature. We should have had great difficulty in helping ourselves from the pipes in our houses, as, owing to the heat of the sun, the pipes were comparatively cool. Wherever glass as a covering can be secured, a considerable acceleration to all crops can be given when, in addition to storing up the sun's rays, the help of warm waterings can also be afforded. Much of the waterings in spring with cold spring water does harm instead of good. Even in bright weather it would often be better to surface-stir and mulch. Heated water would warm the soil instead of cooling it.

FRUIT GARDEN.

Finished all pruning, and will finish the nailing as soon as we can. The birds having commenced on our dwarf Apple trees, we have had them all syringed with lime and soot. If we can keep the birds off a short time longer they will be all right. Our Gooseberries are safe now, and green enough to resist a rather sharp frost, and we have just thinned them, as we have long given up pruning in winter. We wait now until we see whether the birds or we are to have the mastery. This season we have no reason to complain. Currants we have been obliged to colour like the Apple trees, as the birds, having missed the Gooseberries, seemed bent to be revenged on them.

Strawberries.—Ran the hoe between the rows so as to cut up anything that might be coming, and ere long will rake off the roughest part of the manure placed as surface-dressing. Presently we will plant-out the plants that were forced earliest. Plants in pots have needed much water, and even the latest of them are now showing well, ready to go where an opening with plenty of light can be given to them. Amongst a great number we find a few very strong plants of various kinds that have shown, and will show, no flower truss, and these we have turned at once to the rubbish heap. We dislike all plants for forcing that, if of last year's runners, make two or three crowns or buds, instead of one prominent hold one. All plants with pointed crowns and buds are generally best put aside. We have proved often and often that some of these fruitless plants when planted-out will regain their fertility; but in the great majority of cases we have found that they continue barren, producing little or nothing but huge masses of leaves, so that we strongly advise all those having small gardens and only a little space for Strawberries to select their runners from fertile plants only. We to a great extent secure this by planting-out forced plants, as, of course, we keep none but those that have fruited. In some few cases in early forcing the fruit bud after it shows may be starved, shrivelled, or damped, and such plants are just as good for planting-out as those that had fruited. Some kinds are more apt to be barren than others. Some years ago, for a late supply we used to grow the Elton, and were generally successful; but we recollect among good-bearing rows having a small row that would not bloom, and the plants yet looked all right, and we could not make them bloom, and the runners taken from that row were just like their parents, grew well, but never threw up a truss of bloom, though we tried them two seasons consecutively.

Apricot Trees on Walls.—We had purposed allowing these to take their chance this season, as we had no good covering to give them, and we knew that if the bloom was tolerably dry, it would take a considerable degree of frost to injure it; but when, eight days ago, we had snow, sleet, and driving rains, we thought if we should lose a crop, we would not easily forgive ourselves if we did nothing. By means of a few poles placed about a yard from the wall, we hung a net in front, and by means of a rod along the poles, fastened some long thin

branches of laurel outside the net, so thickly as to oppose a barrier to wet passing readily to the wall, and yet so thin to allow the rays of the sun to pass freely between the foliage of the laurel. As yet the fruit is setting, and all safe, though a few blossoms have dropped—often an advantage, as it saves some thinning afterwards. In many books and calendars there are directions about disbudding Apricots and Peaches as early as this, and, no doubt, they may be applicable to warm places in the south, but north of London we prefer little disbudding, or rather removing shoots, unless it be some strong foreright ones, until May, as the young shoots if rather numerous act as a good protection to the young fruit, and even then partly for the above reason, we go over the trees often, removing only a few at a time, so as not to check growth too much at once.

In looking over the trees in the orchard house we found half a dozen shoots plastered with our old enemy the brown fly, and they were quickly removed. If such an insect should appear where the shoot was wanted, we would wash with weak tobacco water, or, what we prefer, quassia water, as that leaves no unsightly appearance behind it. It is difficult to smoke these open houses, and we do not like to do it when the trees are in bloom; but as yet we have had no necessity, for no insects, except in these few cases, have appeared, and on this day, after a keen inspection, we failed to discover more. No syringing has been given them since they were syringed with hot water in winter. To the preventives then used we attribute the present healthy appearance and freedom from insects.

ORNAMENTAL DEPARTMENT.

Much potting, changing plants in conservatories, and hardening-off bedding plants by placing them in earth pits temporarily, much of the work alluded to last week being now done. Calceolarias were removed from the glass-covered pit, the soil was then removed, a little warm leaves placed in the bottom, rotten dung on the top, and then rough somewhat rich soil in which we shall plant Verbenas, whence they will rise in nice balls at bedding-out time, and do better than if planted out from pots.—R. F.

COVENT GARDEN MARKET.—APRIL 8.

A QUIET week and large supplies have caused reductions that sales may be effected, otherwise much perishable produce must be carted away as rubbish, a quantity having to stand over for another day.

TRADE CATALOGUE RECEIVED.

J. Ilman, Wellington Nursery, Strood, Kent.—*Catalogue of Ferns.*

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

BOOKS (*Timothy T.*)—The "Cottage Gardener's Dictionary." You can have it free by post from our office if you enclose *6s. 8d.* stamps with your address. (*A. F. Horncastle*).—If you enclose seven postage stamps

with your address, and order "Heating, by R. Fish," you will have it sent free by post. It contains very full information on the subject.

CALABAR BEAN (*Medicus*).—The most accessible account is in that excellent work of reference now completed, "Chambers's Encyclopædia," from which we extract the following:—"Calabar Bean, a very remarkable medicinal agent, which has just been introduced into the new edition of the 'British Pharmacopœia' (1867). It is the seed of *Physostigma venenosum*, a twining, half-shrubby plant, a native of Western Africa, and the natural order Leguminosæ, sub-order Papilionaceæ, nearly allied to the Kidney Bean, but of a genus distinguished by the hood-shaped stigma, and the deeply furrowed hilum of the seed. The following are the leading characters of the Bean itself: 'About the size of a very large horse bean, with a very firm, hard, brittle, shining integument, of a brownish red, pale chocolate, or ash grey colour. Irregularly kidney-shaped, with two flat sides, and a furrow running longitudinally along its convex margin, ending in an aperture near one end of the seed. Within the shell is a kernel, consisting of two cotyledons, weighing on an average about forty-six grains, hard, white, and pulverisable, of a taste like that of the ordinary edible leguminous seeds, without bitterness, acrimony, or aromatic flavour. It yields its virtues to alcohol, and imperfectly to water.' It is used in the form of an emulsion by the natives of Africa, as an ordeal when persons are suspected of witchcraft. About twelve years ago, Dr. Christison very nearly fell a victim to his zeal for science in experimenting on some specimens of this Bean which had been sent to Edinburgh by some African missionaries. In twenty minutes after taking twelve grains of the powdered seed, he was seized with giddiness and a general feeling of torpor; on which he took an emetic, and thus emptied his stomach. The giddiness, weakness, and faintness, however, increased to such a degree, that the physicians who were called in found him prostrate and pale, with the heart and pulse very feeble and irregular, and the faintness so great as to threaten immediate death, the mental faculties remaining perfectly clear. He complained of no pains or uneasy feelings, nor did the faintness of the heart's action give him any discomfort. Under the use of stimulants, warmth, pulsation, and the power of moving gradually returned, and the next day he was quite well. In 1854, fifty children were poisoned by eating these Beans, which were swept out of a ship at Liverpool. A boy aged six years, who ate six Beans, died very rapidly. It has been tried medicinally in small doses (one to four grains of the powder, or one-sixteenth to one-fourth of a grain of the extract) in chorea, tetanus, and other diseases of the nervous system; but its value as an internal medicine can hardly be said to be as yet established. Its principal use at present is to produce contraction of the pupil. This can be done by introducing into the eye either a minute quantity of the extract, or of paper, or gelatine rolled in a sheet, saturated with the extract, and divided into small squares, one of which is sufficient to produce the desired effect, which commences in about ten minutes, and lasts for about twenty hours. It is regarded as a very valuable addition to our ophthalmic remedies."

NURSERYMEN (*R. M.*).—We never recommend tradesmen. The plants could be supplied by any nurserymen who advertises in our columns.

PORTABLE BOILER FOR CONSERVATORY (*G. S. H.*).—Any of the portable boilers advertised in our columns would suit your purpose. A small saddle-back boiler, if fixed in the passage beneath the conservatory, would also suit the purpose. Two 4-inch pipes in front of the house would keep out frost. We do not much fancy two inch pipes, but three 3-inch pipes would do, and would heat sooner. However placed, the pipes will be an eyesore on the door so paved with ornamental tiles. We would have had all the heating medium beneath the floor. We presume you will have no difficulty in taking the smoke from the boiler or stove in the passage. The simplest plan of all to heat such a house would be to make a brick stove in the passage, with smoke funnel from it; build a chamber all round, with 5 inches of an opening, and from that chamber have an opening for the heated air to rise into the house. The walls of a dwelling house give great protection. In a glass case nearly double the width of yours, and not quite so lofty, Scarlet Pelargoniums stood for the last and the preceding winter without any artificial heat, except opening the door that led from the living-room for an hour in a very cold night. A gas stove in the house would give least trouble, as it could be taken away from the middle of March to the end of October; and a stove for the burner at one end, and the heated air passing through a pipe to the other, would be the simplest. For the whole system of heating by gas, see plans and explanations in a recent number. It is well to think of heating before laying the floor down. The stove would be the simplest, and an opening in the floor if near the middle of the house would be sufficient to keep out frost. One objection to such stoves is, that they will not draw with a long horizontal pipe unless that is taken to a lofty chimney. If you disliked a brick stove you could have a small iron stove, with funnel for smoke, &c., and surround it with a case of sheet iron, after leaving a vacant space all round. Some stones and gravel could be placed in the lower part of this space, and if that were kept moist the heated air that passed through the small grated opening, say 9 inches square, would be as humid as desirable. Better still, a vessel of water could be placed, not on the top of the stove, but 2 or 3 inches from it; and the dry air would be sufficiently moistened without being too much saturated before entering the house.

SHUTTING UP STOVES, &c. (*C. P.*).—The time for shutting up forcing and orchard houses depends on the weather and what is wanted. As to the orchard house, we shall have remarks next week. Generally houses are kept open too long. Sun heat is the best and cheapest heat. In such weather as we have had in the last days of March and the beginning of April, from three to four o'clock would be a good time. In a range of houses with a wall at each end, we generally shut up the west end first—say about three o'clock, the east end latest, and the intermediate divisions accordingly. Supposing your night temperature to be 65° or 70°, we should not object to the temperature of the house rising to 80° or 85° with sun heat after being shut up. In close-glazed houses we would shut off the bulk of the air early in the afternoon did we even leave a little air on all night, and this we would do where fuel is cheap. By leaving on full air until five or six o'clock you must use much more fire heat; or by shutting up then you will have as high a temperature in the evening and at night as you had in the afternoon; whilst the teaching of nature would say, Proportion your heat to the sunlight.

WHITE MARSEILLES FIGS FALLING (*J. S. Gordon*).—You should have told us how you grow your Figs. If in pots, they will cast some fruit every time the soil becomes dry. They will do the same if grown in a

narrow border. If you have given plenty of water, and not so much as to make a morass from undrained soil, and they still drop, ring the branches by shipping out one-eighth of an inch of bark some distance below the fruit.

RIBBON BORDER (*Westminster*).—We presume you mean seeds that you can sow at once; then the following would look well, beginning at the back or north side of the 4-feet border—viz., first row, Blue Branching Larkspur; second row, Prince's Feather, or Love-lies-bleeding; third row, Coreopsis Drummondii; fourth row, Silene pendula ruberrima.

PELAGONISMS (*Homunculus*).—Both of your two lists. If anything, Lucy Grieve would turn the scale. It is a lovely plant. Victoria Regina is also good.

VINES (*W. H. T.*).—Your proposed Vines in pots are well selected. We would plant out three Black Hamburghs, one Buckland Sweetwater, one Royal Muscadine or one Ewood Muscat. For the late vinery we would have three Hamburghs as proposed, two Lady Downe's, one Calabrian Raisin, and one Ewood Muscat.

GRAFTING HOLLIES (*Rever*).—Your Green Hollies about the thickness of a lead pencil would answer well for grafting, and no time should be lost in performing the operation. You may graft them close to the ground, and after claying draw the earth to the stocks so as to cover the clay. It would not do to take the stocks up and graft them before planting. They should be left where they have been for the past twelve months. Whip-grafting is the best. If newly planted, we fear the grafts would not take, but we have not tried it.

WIRE TRELLIS FOR STONE WALL (*A. O. H.*).—The sloping buttresses will not prevent your having horizontal wires. As the buttresses only reach about half-way up the wall, the upper part can very easily have horizontal wires fixed, and a straining plate of iron will only be required at each end for that part of the wall, and between each buttress you have only to put the same number of straining plates, close to each buttress, and you will thus treat the space between each as if the wall terminated there. The buttresses, of course, will not be wired. It will be less costly to wire the wall horizontally than vertically. For the latter you will require a plate of iron at the top and along the bottom of the wall, and the wires must be put up perpendicularly. The expense will be about double that of horizontal wires, and in our opinion the trellis will not be so good for training. You may have diamond-meshed trellises that would cover the wall to a nicety, and if with 4-inch meshes they answer very well. We have a trellis of this kind, and it looks well. It is thus made: quarter-inch wire all round serves to form a frame, and from this the wires, No. 12, run obliquely and form 4-inch lozenges. It is galvanised, and fixed to the wall with holdfasts.

LIFTING PYRAMID PEAR TREES (*Idem*).—So long as the trees remain fruitful, making no gross growths, and forming bloom buds plentifully, it is not necessary nor desirable to lift and root-prune them; but if they grow very vigorously, and make a quantity of wood that cannot be stopped or summer-pruned be induced to form flower buds, then lifting would be desirable, as it checks growth and tends to encourage the formation of fruit buds. In your soil we should think lifting would not be often required, if at all.

REPOTTING FERNS (*Perplexity*).—The best time to repot Ferns is March, or when they are recommending growth. November and December are the worst months in the year for repotting Ferns. Repotting at that time would no doubt help to cause their death; but we think their being kept in a cold vinery would be sufficient to cause the destruction of such kinds as Nephrolepis, which need a temperature of not less than 45° at night. If kept in a cool house they should not have much water—no more than enough to keep them fresh.

POURING WATER ON HOT-WATER PIPES IN FERNERY (*D. R. C.*).—It is a bad practice, and worse than useless for the destruction of the mealy bug. The black fungus will disappear when the mealy bug is destroyed. Instead of pouring water on the pipes we would advise you to sprinkle the floors, walls, and every available surface with water twice daily, morning and evening, keeping them always moist, but avoid wetting the fronds of the Ferns. As to the mealy bug, we would lay all the plants infested on their sides, and syringe them forcibly on the under side of the fronds with water at a temperature of 120°, turning them round. A few washings will probably clear the plants, and they may be kept clean afterwards by going over them frequently with a moist sponge, and wiping off every trace of the mealy bug. You may by pouring water on the hot-water pipes so damage the fronds of the Ferns that a twelve-month's growth will be required for their recovery.

LEAVES FORMING BUDS (*Idem*).—You will find a full explanation of the theory of propagation by leaves, for which we cannot afford space, in Johnson's "Science and Practice of Gardening," pages 268 to 277 inclusive. You can have the book post free from our office for 3s. 10d. in stamps.

BIRDS versus POLYANTHUSES (*F. P. G.*).—The only plan we know of that will keep them off is to put in small sticks, and about 9 inches out of the ground, and stretch black worsted from stick to stick, putting a double line of worsted along each line of plants. We find it best to put the lines of worsted about 6 inches from the plants on each side, crossing the worsted from stick to stick as well as stretching it straight along the rows. It is placed 8 or 9 inches from the ground. We find this effectual.

HYACINTHS AFTER FLOWERING (*A. H.*).—The plants should be kept in the pots in a light airy position in a cool house or frame until the foliage is well ripened. They ought not to be exposed to frost, and should be well supplied with water; when the foliage turns yellow gradually discontinue watering; withhold water altogether when the foliage is yellow. When it is completely so, turn the plants out of the pots, shake away all the soil, and place them on shelves in a cool airy shed to dry. When thoroughly dried remove the dead leaves, old roots, and all offsets, and pack the bulbs away in dry sand in a dry cool place, where they may remain until the following October, when they should be planted in good, rich, light, well-drained soil, with the crown 1½ to 2 inches below the surface, giving as a mulching over the ground about an inch thick of partially decayed leaf mould in December, before severe weather set in. The mulching may remain during the winter, and be neatly pointed-in in March. You will see by this that we do not advise the growing of Hyacinths in pots the second year; but we consider them very desirable and fine for out-door decoration.

SOWING PASSIFLORA EDULIS SEED (*Ada*).—The seed should now be sown in pots well drained and filled to within half an inch of the rim with a

should be potted in a compost of equal parts turfy sandy peat and fibrous sandy loam, good drainage being provided, for if the soil in the pot ever becomes waterlogged the plant seldom thrives. If the peat be deficient in sand, silver sand should be added liberally. The soil ought never to be allowed to become so dry as to affect the foliage. A temperature of from 50° to 55° is sufficient, giving plenty of air and water when growing, with a position near the glass. Keep the plant underpotted rather than overpotted, for it thrives best when the roots reach the sides of the pot.

VINE BLEEDING (*Rector, Kent*).—The best remedy that we know of for the bleeding of Vines is Thomson's styptic. Applied to the end portions of the wood it will stop the bleeding. If you prefer it, the ends may be seared with a red-hot iron until dry, and then be dipped in boiling tar and pitch; or rub into the pores of the wood (without the charring), a paste formed of one-third calcined oyster shells beaten to a fine powder in a mortar, and two-thirds cheese, working together until a paste is produced.

ARUMS—CAMELLIAS (*C. M. Major*).—There is no special work on the Belgian mode of growing either Arums or Camellias for specimen plants. The modes well known to all gardeners are sufficient. The pyramidal form of the Camellias exhibited at Ghent depended upon their training. The cause of the Camellia flowers not expanding no one can tell without knowing how the plants were treated. The roots may have been kept too cold, too dry, or too wet.

ANTS (*J. Beausire*).—No mode of banishing them is more effectual and obnoxious than sprinkling guano over their haunts.

HOTTEST PERIOD OF THE DAY (*J. T.*).—The sun's rays are most heating between one and two in the afternoon; but the highest temperature in the shade is not generally attained until between three and four.

NAMES OF FRUIT (*C. G.*).—Your Apples are—1, Beauty of Kent; 2, Duncow's Seedling; 3, Scarlet Nonpareil.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY EXHIBITIONS IN GENERAL.

CLASSIFICATION OF GAME FOWLS.

(Continued from page 264.)

PENS for single hens and pairs of hens without a cock have always appeared to me both absurd and useless, as a waste of room, and as using too many pens; and few purchasers buy hens for crossing with, or hens alone, but always purchase good cocks for crossing. I think a cock and three hens in each pen, as at first at Birmingham, are too many, and a cock and one hen to each pen too few, though this prevents the Game hens from fighting. A cock and two hens in each pen are, I think, the right number, the most correct and proper match for polygamous birds, better for sale, and for the size of both the pens and hampers in general use.

Full-grown cocks only should be shown as single cocks, as stags and cock chickens, not being spurred, can scarcely be termed cocks in the strictest sense of the word.

All the birds in each pen should, of course, perfectly match as to the relative size of the hens to the cock, as well as both hens being of the same size, and matching exactly in shape and feather, and in the colours of the eyes and legs, and if not matching should be at once disqualified from competing for cups, prizes, or commendations.

Fowls should never be too highly fed at exhibitions, but should have one good meal at least per day, but not so much as to distend their crops in the least, as this always looks bad. Water in small quantities should be often supplied and, of course, quite clean. The floors of the pens should be sanded or sprinkled with dry sawdust, the sand dry as well.

Pens are, perhaps, best fitted with perches to put up and take down. These should be taken down at daylight and put up in the evening, or when the exhibition is closed for the night, and then the birds will never lay in their own excrements. Fowls are seldom overfed at exhibitions, and over-feeding is very bad for them; so is starving them, of course.

The counties which have been most celebrated for the breeding of poultry are these:—Surrey, Sussex, and Berkshire, for Dorkings and the supply of London; Hertfordshire, which also has excellent fowls and supplies London; Devonshire and Somersetshire, which supply it largely; Yorkshire and Lancashire for Hamburghs and Game fowls; Buckinghamshire for Ducks; Lincolnshire for Geese; Norfolk and Cambridgeshire for Turkeys.

Hertfordshire chiefly supplies the north of London with poultry, and Surrey and Sussex the south and west of London in the same way, being the nearest of the best poultry counties to London.

The Birmingham Exhibition being in North Warwickshire,

which is the central district of England, will always, in all probability, be our chief poultry show. The Crystal Palace and the Bath and West of England Exhibitions used to rank next, but of late years the Manchester Exhibition certainly stands next to Birmingham, the Crystal Palace having given up. Manchester ought to be first-class for Game fowls in its situation.—NEWMARKET.

P.S.—In my last communication in page 264, in the seventh line from the top of the first column, read "November or the first week in November," and not December.

BUCKWHEAT FOR FOWLS.

You consider it not good as poultry food, but I always use it from Christmas till May; and the consequence is, I have eggs before any one else. I have this year sent nests to all my friends, even from hens, long ere they had any, and I attribute it to the buckwheat; whilst I can testify that when mixed they always pick it out first from all other grain.—NEMO.

ACCRINGTON POULTRY SHOW.

Few amateurs anticipated so excellent a Show at this season as that held on the 2nd inst. The competition was of a first-rate character throughout, and the entries amounted to five hundred pens. As an agricultural show was combined with it, the attendance was excellent, and the weather could not have proved more favourable. There is one point in the general arrangements open to great improvement, that of the public having unrestricted admission long prior to the commencement of the judging. From this cause alone, the poultry being all placed in one continuous tier, the two gentlemen who officiated as Judges were compelled to "elbow their way" backwards and forwards during the determination of the premiums, among a dense mass of general visitors, and still more personally interested exhibitors. This error was all the greater, inasmuch as the Judges were not permitted to commence until after eleven o'clock, at which time the Committee and Judges were marched to the Show ground headed by a local brass band. With a very little extra exertion in promptly penning the birds, and commencing early in the morning, every prize-card might easily have been affixed by the time just named, in lieu of that at which the awards began, besides which the finances of the Society would rather have been benefited than otherwise. With an energetic staff of "feeders," to place the birds quickly in position, the Judges at this time of year might easily have been at their duties by 7 A.M., and a trial of this suggestion will, no doubt, prove beneficial in future years. We allude to this oversight because the Committee of Management is evidently most anxious to improve the annual Show by the greatest personal exertions.

All of the *Hamm* classes were most excellent, and the competition lay among many of the best specimens of the day. Nor were the *Game* *Brahmas* less worthy of especial mention. It is but rarely that *Hamburghs* muster so numerously, or of so good quality, even at our largest shows, as they did on this occasion. Some especially good *Spanish* fowls were shown, but, as might be expected, not a few lacked the condition always essential to success. *Brahmas* and *Cochins* were good, and the *Polands*, though few, were capital. In the Variety class

were shown some of the best Cuckoo-coloured Cuchins ever yet exhibited. The "Selling class," to come under the hammer at 3 p.m., brought together a very large entry.

The *Turkeys* and *Geese* throughout were so good as to be a credit to any show; nor were the *Ducks* much less worthy of note, and the variety Duck class was one of the most popular of the meeting.

In *Pigeons*, numbers of most excellent specimens were present, but the pens were decidedly too low and too deep for these birds to be seen to advantage. As the time for closing the Show was so early as 4 p.m., this portion of the Exhibition was especially thronged.

GAME (Black and Brown Reds).—First, C. W. Brierley (Black Red). Second, E. Aykroyd, Bradford. Third, J. Fletcher.

GAME (Any other variety).—First, W. Boyes (Duckwing). Second, J. Fletcher (Piles). Third, J. Lanning, Spalding (Duckwing). Commended, W. A. Taylor, Manchester (Duckwing); C. W. Brierley (Duckwing).

DORKINGS (Any colour).—First, J. White, Waralaby, Northallerton. Second, Mrs. M. Seamons, Aylesbury. Third, J. Robinson, Garstang (Grey). Highly Commended, D. Gellatly, Meide; W. Parr, Patricroft, near Manchester. Commended, Mrs. E. A. Dale, Scarborough (White).

CUCHINS (Buff or Cinnamon).—First, T. Stretch, Ormskirk. Second, and Third, W. A. Taylor (Buff). Highly Commended, W. A. Taylor (Buff); C. Sidgwick, Keighley (Buff). Commended, R. Duckworth, Sheep Hey, near Ramsbottom.

CUCHINS (Any other variety).—First and Third, R. Smalley, Lancaster (White). Second, T. Stretch Partridge. Highly Commended, T. Wrigley, jun., Middleton (Partridge); T. Bott, Bury (Partridge).

SPANISH (Black).—First, H. Beldon, Goutstock, Bingley. Second, J. Newton, Silsden. Third, H. Wilkinson, Early, near Skipton. Highly Commended, J. Thresh; J. Newton, Silsden, near Leeds; Messrs. Burch and Boulter, Sheffield. Commended, Hon. Miss E. Douglass Pennant, Bangor; W. F. Pickard, Thorne, near Leeds.

BRAMAS (Any colour).—First and Second, E. Leech, Rochdale (Dark). Third, Hon. Miss E. Douglass Pennant (Dark). Commended, C. W. Brierley; T. Pomfret, Houghton Lane, Preston.

HAMBURGERS (Golden-pencilled).—First and Third, H. Beldon. Second, H. Pickles, jun. Highly Commended, J. Fielding, Newchurch; H. Beldon. Commended, T. Wrigley, jun.

HAMBURGERS (Silver-pencilled).—First, Second, and Third, H. Beldon. Highly Commended, T. Sharples, Crawshawbooth.

HAMBURGERS (Golden-spangled).—First, N. Marlor, Denton, near Manchester. Second, H. Pickles, Skipton. Third, W. D. Hyde, Harst, Ashton-under-Lyne. Highly Commended, E. Brierley, Heywood; H. Beldon; W. Parr. Commended, J. Lanning, Spalding.

HAMBURGERS (Silver-spangled).—First and Hamburg Cup, H. Beldon. Second, H. Pickles. Third and Highly Commended, J. Fielding. Commended, H. Beldon.

HAMBURGERS (Black).—First, J. Fielding. Second, Messrs. Walker and Mason, Denton, near Manchester. Third, W. Parr. Commended, C. Sidgwick.

HAMBURGERS (Any variety).—First, H. Beldon. Second, R. Bee, Goosnargh, Preston. Third, E. Brierley, Heywood (Gold-spangled). Highly Commended, T. Wrigley, jun. Commended, H. Pickles, jun. **HEA.**—First, H. Beldon. Second, J. Newton. Third, H. Pickles, jun. Highly Commended, J. Lancaster, Burnley. Gold-spangled; W. A. Taylor; J. Fielding. Commended, T. Wrigley, jun.

POLANDS (Any colour).—First, W. Harvey, Sheffield. Second, H. Beldon. Third, P. Unsworth, Lowton, Newton-de-Willows. Highly Commended, P. Unsworth; H. Beldon; W. Pickard. Commended, H. Beldon; W. Harvey.

ANY OTHER VARIETY.—First and Second, Col. Stuart Wortley, London (French). Third, R. Loft, Woodmansey, near Beverley (White Sultan). Highly Commended, J. Sichel, Timperley (Houdans); H. Beldon (Clove-Cour). Commended, D. Parsons, Preston (Cuckoo Dorkings); J. Sichel (Crève Cour); G. Huxter, Stillingfleet, Yorkshire (Malay).

SELLING CLASS (Any variety).—First, W. A. Taylor. Second, W. Bulcock, Burnley (Black Red). Third, G. C. Furness, Accrington. Highly Commended, J. & C. Furness; J. Rhodes, Accrington (Black East Indian Ducks); Messrs. Woodworth & Hargreaves, Oswaldtwistle (Polands); J. Robinson, Failandworth (Dorking); H. Beldon; J. Jackson, Bury. Commended, H. Wilkinson, Early, near Skipton (Black Spanish); C. W. Brierley; G. Anderton, Accrington; W. Boyes.

GAME BANTAMS (Any variety).—First, H. Shumach, Southwell, Notts. (Black Red). Second, J. S. Senior, Dewsbury. Third, C. W. Brierley.

BANTAMS (Any other variety).—First, W. A. Taylor. Second, T. Burgess, Brighouse. Third, Hon. Miss E. Douglass Pennant (Gold-laced). Highly Commended, J. Shackleton, Halifax (White-laced); W. H. Tomlinson, Newark-on-Trent (Black); R. E. Riley, Ovenden (Black); Messrs. Tonkin and Tuckey, Bristol (Black); T. C. Harrison, Hull; S. & R. Ashton, Mottram, Cheshire. Commended, — Bowden, Marchinton, Uttoxeter (Black); Mrs. Dale (White); N. Marlor.

TURKEYS.—First and Second, E. Leech. Third, T. Houlker, Revidge, Blackburn, Cambridge. Highly Commended, W. P. Pickup, Spring Hill, Accrington (Black Norfolk); T. Houlker.

GESE.—First, E. Leech. Second, J. Lancaster. Third, G. Huxter, Stillingfleet Vicarage, Yorkshire. Highly Commended, J. Huxter, Longridge; T. Briggs, Colcoats Hall. Commended, T. Houlker.

DUCKS (Aylesbury).—First and Second, Mrs. M. Seamons. Third, Bowman & Fearon, Whitehaven.

DUCKS (Konek).—First, T. Bott, Woodlands, Bury. Second, J. J. Scott, Rochdale. Third, J. G. Broxup, Burnley. Highly Commended, D. Parsons, Cuerden, Preston; J. West, Worsthorne; T. Bott; W. Parr; E. Leech.

DUCKS (Any other variety).—First and Second, C. W. Brierley. Third, W. Laycock, Woodville, Keighley (Carolina). Highly Commended, T. C. Harrison; H. Beldon (Callis); T. C. Harrison; S. & R. Aston (Carolina); Rev. W. Sergeantson, Acton Burnell (Carolina). Commended, Mrs. Clarke, Bedford (White Peruvian); S. Burn, Whitley (Black East Indian).

ANY VARIETY (Except Game and Game Bantam, within three miles of Accrington).—First, Mrs. G. Furness, Accrington (Cuckoo Cuchins). Second, B. Carlisle, Rishton (Brahmas). Third, G. Duckworth, Church (Silver-spangled). Commended, G. & C. Furness (White Bantams).

SINGLE COCKS.

GAME (Any colour).—First and Game Cup, W. Wheeler, Carlton, near Nottingham (Black Red). Second, J. Fletcher, Stoneclough, near Man-

chester. Third, J. H. Wilson, St. Bees, Cumberland (Black Red). Highly Commended, J. Fletcher; C. W. Brierley, Middleton; F. Sales, Crowle, Lincolnshire (Black Red); W. Boyes, Beverley. Commended, W. Boyes. **GAME (Within three miles of Accrington).**—First, W. Westall, Baxenden, near Accrington (Brown Red). Second, W. Morris, Accrington (Black Red). Third, W. Boothman, Accrington.

GAME BANTAM (Any colour).—First and Cup, J. J. Consins, Leeds. Second, J. Crossland, Wakefield (Black Red). Third, T. Whittaker, Melton Mowbray. Highly Commended, J. Lamber, Accrington; Bowman and Fearon. Commended, J. W. Morris, Rochdale; T. C. Harrison.

GAME BANTAM (Within three miles of Accrington).—First, C. Smalley, Oswaldtwistle (Black Red). Second, A. Riley, Accrington (Brown Red). Third, G. Birtwistle, Haslingden.

PIGEONS.

CARRIERS.—First, H. Yardley, Birmingham. Second, J. S. Skidmore, Nantwich.

TUMBLERS.—First and Second, J. Hawley, Bingley.

BARNS.—First, J. Firth, jun., Dewsbury. Second, A. Laycock. Highly Commended, J. Walker, Newark, Notts.

OWLS.—First, A. Dove, York. Second, H. Yardley. Highly Commended, E. D. Graham, Birkenhead.

POUTERS OR CROPPERS.—First, H. Beldon. Second, J. Hawley. Highly Commended, J. Hawley; H. Yardley.

FANTAILS.—First, H. Yardley. Second, H. Beldon. Highly Commended, J. S. Skidmore, Nantwich; T. Denton, Southwam.

TREBLES.—First, J. T. & J. Sykes, Rochdale. Second, J. Thompson, Bingley. Highly Commended, J. Thompson; H. Yardley; H. Beldon.

DRAGONS.—First, H. Yardley. Second, W. Harvey. Highly Commended, T. Houlker. Commended, T. Houlker; J. Robinson, Failandworth, Manchester.

TRUMPETERS.—First, J. Firth, jun., Dewsbury. Second, J. Hawley. Highly Commended, H. Beldon; J. Thompson; J. Hawley. Commended, J. Thompson.

ANY OTHER VARIETY.—First, H. Yardley. Second, J. Skidmore (Spots). Highly Commended, H. Yardley; J. Thompson; J. Hawley (Red Jacks); H. Beldon.

ANY OTHER VARIETY (Within three miles of Accrington).—First, Withheld. Second, T. Kenyon, Accrington (Black Turbites).

Mr. Hewitt, of Birmingham, and Mr. Tebbay, of Preston, were the Judges.

MR. JOHN MATHEWS EATON.

We learn from the *Field* that this enthusiastic, eccentric, Pigeon-fancier died at Chertsey as long since as the 19th of October last.

He was a tailor, but abandoned his business at Islington to devote himself to Pigeon-dealing. The Short-faced Almond was his favourite variety, and he considered a good specimen only surpassed in beauty by woman; and he had reason to consider it even superior to the individual he took to be his wife. From her he was separated, and found a more congenial companion and friend in Mr. Dean Wolstenholme.

His "Treatise on the Almond Tumbler," published in 1851, is little more than a reprint of Boyce's, which appeared in 1802; and his "Treatise on Pigeons," published in 1852, is a most irregular mixture of old Moore's "Columbarium" and notes furnished by our correspondent the late Mr. Brent.

DEFECTIVE-PLUMAGED POUTERS: THEIR USE, ABUSE, AND DISUSE.

ALTHOUGH colour has been the principal feature of this discussion, I propose, with the indulgence of your readers, to include a more direct consideration of the markings.

But before resuming may I inquire why so interesting a subject should not be discussed strictly on its merits, and quite apart from personalities and charges so totally gratuitous and unsustainable as haste, rudeness, &c.? It must be a poor case indeed that stoops to aid so unequivocal; nor can the merits of the question be in the slightest degree affected by the number of Pouters any of your correspondents may, or may not, have to spare.

My article of February 6th was written without a tinge of personality, was intended for general rather than particular application, and resulted from the patient (not hasty), study of the last two annual Glasgow shows. If I brought to such study some practical experience, I really must apologise for a fault of which it is now impossible to divest myself—a fault, indeed, which I share in common with my late censors. I am guilty, too, of withholding facts in support of my suggested remedy for bad colour, the which it appears I should have advanced "before condemning (b) the method of breeding followed by the oldest and most successful Pouter breeders." If Mr. Ure's courtesy is not equal to the admission of my experience, neither can it be equal to an admission of the facts comprised in that experience.

The "improvability of properties by selection," scarcely needed the intrusion of any facts of mine in its support, for it is endorsed by facts in the possession of every breeder, and

patent to every observant naturalist. Passing over, then, the seeming inconsistency that such facts should be required at all by "an old fancier" (especially in the face of the instance he has adduced in my favour), let it suffice to say that in common with the majority of fanciers, I have ever found colour a most controllable property, and that the German breeders, who make plumage their especial object of cultivation, are continually illustrating its subjection to careful selection.

So far from "condemning" the method of breeding, my article positively and clearly asserts its value, and only questions the departures from, or the one-sided application of, a principle ever the guide of painstaking fanciers. The results best test the method; to these, as illustrated in the late Glasgow shows, I have pointed, and from them shall continue to deduce further observations. These exhibitions are public, and I have yet to learn that my remarks have exceeded the bounds of truth or fair criticism.

We have seen that "selection" is the one principle relied upon by fanciers for the attainment of their results, that under its influence Pouters have made great progress in size and form. We have noticed that no such progress can be claimed for plumage; that while it is admitted that the markings may be improved with tolerable ease, and that in colour certain combinations are recommended and others condemned, yet the applicability of "selection" as a means of improving plumage has been questioned. We have further seen that no better, or, indeed, different principle for guidance has been advanced.

One more of these illustrations drawn from Carriers must be noticed. It is stated that "breeders match the best Blacks to Duns without injury to Blacks." This illustration is not nearly full enough to meet the requirements of the argument. It fails to state how often Blacks may be so crossed without injury; it omits to notice the poverty of colour from which Black Carriers are suffering; it takes no account of an essential difference between Carriers and Pouters, the former being whole-coloured, the latter pied; and it suggests a comparison between Dun and Mealy worth more than a passing remark. Although in Carriers, Dun may be considered as Mealy to the Black, yet in Pouters we have no Mealy colour at all the equivalent of Dun in intensity. Admitting that Dun Carriers may be frequently crossed with Blacks, does it follow as a necessary sequence, that the far-less-intense Mealy Pouter can be as frequently and as usefully employed, to say nothing of the markings—an element not without its weight in such a comparison?

It will scarcely be a digression here to state, that Carriers are displaying to a considerable extent the evils of one-sided selection, and that the partiality of breeders for "head" properties is resulting in some loss of that exquisite shape which should be a distinguishing characteristic of this remarkable variety.

Since my assertion of deteriorated colour is disputed by Mr. Ure, it may be desirable to offer some analysis of the coloured Pouter classes at the last Glasgow Exhibition. This at any rate will determine the present condition of plumage, even if it fails to endorse my views. On the occasion named, 138 birds were exhibited in the old classes as Pied Pouters of standard colour, against sixty-one Meales, Chequers, Splashes, &c. But before any approximate estimate of plumage can be formed these numbers require modification. From the 138 Pied Pouters, one-sixth at least must be deducted for birds too impoverished in colour fairly to rank in a standard class, and another sixth for birds of very indifferent markings, although of passable colour. By adding the forty-six birds thus deducted to the sixty-one figuring in the defective classes, a comparison of some importance is reached—good plumage being represented by ninety-two birds, whilst bad plumage claims at least 107. Nor are these deductions needlessly severe. It would probably be much nearer the mark to subtract one-fifth, or one-fourth even, in each case. No provision having been made for the exhibition of young Chequers, Grizzles, or Splashes, the young classes cannot figure in this illustration, but if they did similar deductions would be necessary.

As the best birds are brought out for exhibition and the worst left at home, it is more than probable that the foregoing statistics somewhat favourably display the proportion of good plumage to bad throughout the fancy, and whether they establish deterioration or not, they assert a condition of plumage open to immense improvement.

If "selection" implies that properties may be developed or intensified by attention, it also implies a non-application or misuse of that well-worn principle when any property exhibits

decline or failure. Is deterioration, then, too hard a name for the present condition of plumage, in the face of such statistics as the greatest Pouter show furnishes, to say nothing of the confessions lately appearing in these columns? Is it beyond the truth to attribute such deterioration or want of development to the known partiality for size and form, and the consequent one-sided exercise of selection?

But what of the future? for this is the question that most requires solution. Guided still by the light of selection, what may be expected from a stock weighted so heavily with defective colour and markings?

Making every allowance for the possible effective use of many doubtful specimens, granting that some may be most legitimately employed for strengthening the White strains, that others (under one ownership), may be matched to neutralise their individual defects, there still remains a proportion of defective plumage far too preponderating to be safely utilised by matches with the sounder birds. Any such attempt would but intensify the present disastrous tendencies, would accumulate in yet increasing numbers Meales, Chequers, Grizzles, and Splashes, would stimulate the production of still weaker colour, would raise further barriers against accurate markings, and would develop the strong bias to undesirable reversion, which is more than ever a characteristic of the Pouter classes in the departments now under consideration. I can, therefore, but re-affirm the suggestions contained in my article of February 6th. Future progress demands a far stricter selection for plumage, the exclusive use for the present of the soundest possible colour, and the temporary disuse of crosses at all likely to injure the markings, dilute the colour, or otherwise impair it in richness, smoothness, or lustre. Persistent efforts in these directions would ultimately establish plumage on a footing not less secure than size and contour. The multiplication of defective specimens would be restricted, the tendencies to unsightly reversions be in a great measure controlled, and birds purer in strain, richer in colour, and more comely in markings, would gradually supplant the well-nigh ridiculous nondescripts so frequently offered for our admiration.

Such selection should be well sustained. If ever our Pouters are to attain to a complete pedigree, they must breed far truer for plumage than they do now. Therefore, I claim for my recommendations more than a passing trial, and urge a perseverance more on a par with that enduring effort which has secured so much to admire in the domains of size, vigour, symmetry, and carriage.

However useful Meales, Sandies, or Chequers, may have proved for developing size and form, the occasion for their continued use on so lavish a scale has passed, or is passing. It is not now a question of raising grand birds from a stock "little better than Pouting Horsemen," as Mr. Ure puts it. The grand birds are already raised; it is simply a question, therefore, of maintaining our ground, while superadding undeveloped or neglected graces.

A sounder plumage thus established, new starting points would be secured for fresh triumphs with stocks far more true and effective. Then, again, might well-bred Meales be judiciously employed to dilute the too intense blue (as already pointed out by that tasteful fancier Mr. Huie), and other defective birds with especial reference to revision of shape, and to that lengthening of limb so much required to carry the increased length of feather.

To recapitulate. It has been shown that the present condition of plumage urgently requires attention; that unless such attention be promptly bestowed the difficulties of the situation will be materially complicated; that the principle of selection judiciously applied fully meets the case; that such selection involves the utmost circumspection in the use of defective birds, if not their temporary disuse; that no degeneracy in size or form need result from the more direct culture of colour and markings, for the circumstances under which a profuse use of defective-plumaged birds was justifiable no longer exist, or are advantageously modified; and, lastly, that artistic considerations demand numerical restriction rather than the perpetuation or multiplication of inferior specimens.

There is yet another aspect of this subject. In the defective classes there are many birds without pretensions to size, form, or excellence of any kind, but which are, nevertheless, used at the expense of every property in a mere eagerness to breed for quantity. This abuse might be effectively checked by a stricter classification of our public shows. On no account should it be possible to show Pouters very defective in colour or markings on equal terms with the standard specimens if shown at all;

but as an accommodation to breeders such birds might be provided for in a defective-plumage class, to be judged solely and rigorously for size, shape, carriage, limb, and constitution; and this system would have the additional advantage of displaying the taste and abilities of our judges in cardinal matters.—W. VOLCKMAN, *London*.

P.S.—Since the above was put in type an anonymous contributor has appeared in a discussion hitherto conducted under *bona-fide* signatures. Much that “DEEDS SHOW” advances or questions is anticipated in the foregoing article. It is somewhat difficult to disentangle the object of his remarks, seeing that he avoids any direct contravention of the principle of “selection,” a principle agreed in and illustrated by the very authorities he quotes, and practised in some form or other by every successful fancier.

A PERUSAL of Mr. Volckman's reply to Mr. Stuart and myself in the Journal of the 26th ult. quite confirms the impression made on my mind by his first article. He first introduced himself as having had a long practical experience in Pouter-breeding. I therefore asked him to give a few facts in support of his views, as such evidence would tell more strongly in his favour, if agreeing with his theory of breeding, than any amount of writing on the subject; but in his reply he does not even allude to this.

Again, in his report to the members of the London societies he says, “that deterioration is going on in almost every strain.” This assertion could only be made by one who is ignorant of what has been going on for the last ten or twelve years; on the contrary, I say most decidedly that great improvement has been going on in almost all the strains; and every fancier who may have seen the earlier Glasgow Shows will, I feel confident, agree with me, and I have not the slightest doubt but the same may be said of the Birmingham and other principal shows. Blacks had very often white faces or ring heads; Blues were much the same; Reds very poor in colour; and Yellows so scarce and inferior that there was no class for them the first year or two. I therefore claim for myself and for the principal Scotch breeders a great improvement even in colour and marking, though no doubt there is plenty to do yet, and we shall always be glad to receive practical hints or to receive more light; but Mr. Volckman has utterly failed to give us this, even to the extent of a farthing rushlight.

My illustration drawn from Almonds is, he says, unfortunate, as breeders are now at a standstill, if not actually going back. Not being at present in the Short-face fancy, I cannot say whether such is the case or not. I certainly think the birds at Glasgow during the late shows would not lead one to think they were sinking, and I know that some of the most successful breeders still adhere to this system; but the Short-face fanciers do not require me to assist them if they should feel aggrieved. This inability to move on, Mr. Volckman says, arises “from one-sided selection at the will or taste of the fanciers,” but he does not say how selection is to be made if not at the will and taste of the fancier. Perhaps the new Society which he has been aiding to form may, in its very comprehensive limits, appoint a committee of taste or a registrar general to decide upon the merits of the candidates for matrimonial felicity—to take care that the gentleman in black does not foolishly ally himself with the young lady in blue, and thereby entail disgrace on their descendants by having to pass through life as despised Chequers or seedy Blacks.

Mr. Volckman seems quite pleased with the fancy that it had taken Mr. Stuart and myself four or five weeks to reply to his first article, no doubt dashed off in as many minutes; but like Snug in the play, we are “slow of study” here in the north. It would, however, have been much better had he taken more time, and waited until he really had something to say worth hearing. Suppose that he had waited a few years to give his pet system of selection a trial to ascertain if it was really better than that which he condemns; if he had done this, and shown us better birds than we have been breeding, it would then have required no persuasion, by long wordy articles or otherwise, to follow his system, as Scotchmen have the name of being wide awake to their own interest. Who asked Mr. Volckman to believe that our present grand strains of Pouters have been bred from Pouting Horsemen?

I had almost forgot to ask, What of the Dun and Black Carriers? I may presume that as Mr. Volckman does not notice this that it is not unfortunate for me.

I think I have now shown that Mr. Volckman has in reality no practical experience in Pouter-breeding, and that he does

not know what has been done by fanciers in raising the various strains to their present comparatively high state of excellence; and in reply to his question of What ought to be done under the present condition and aspect of the Pouter classes? I would simply say, Nothing. The present system has raised those birds steadily; and though not yet all we could wish, I think there is sufficient vitality and power in our system to raise them still higher, or at least we shall let well alone till something better is brought forward.—GEO. URK, *Dundee*.

A GUIDE TO CANARY-BREEDING.—No. 1.

THE Canary lays from three to six eggs, and sometimes but not often seven, and has four or five nests in the season. Four is an average nest. Take out the egg every morning till the third is laid, and on the evening of that day remove the nest in which the hen has been scuffling about for the last week, and replace the eggs in a clean felt securely fastened, and carefully adjusted to the shape of the tin. This is best done by making the felt of a circular shape, and cutting a deep notch in the edge, which will make it fit without a wrinkle by pressing it into the tin. Should the bird have built her own nest, by all means allow it to remain intact, the above process applying only to the artificial nest system. Each has its merits. Try both, and adopt that which succeeds best with you. Some hens evince only a very slight inclination to build; while others are very clever architects, and, true to the instincts of their nature, construct such beautiful nests that, apart from all other considerations, one cannot help regarding them with admiration. I have twenty hens sitting, and have adopted both plans, and so far I decidedly advocate allowing the bird to construct its own habitation, but as the season advances I shall look with some apprehension for the appearance of the little red rascals, on the first sight of which I invariably change the nest instantaneously.

With reference to this matter, I will give an extract from a letter I received this morning from a lady, a valued correspondent. I give it both as an item of experience, and to show your fair readers what an interest our feathered favourites are capable of exciting in the minds of their own sex. My correspondent writes:—“As to nests, I always give my birds moss and hair to make their own in square boxes, which they generally do very nicely. When they do not I make the nest for them, putting moss in the corners and filling up with hair, rounding it with my knuckles and bent hand, and finally finishing with one of my hard-boiled hen's eggs while warm. It is easily done. As for red mites, I am rarely troubled with them. I saturate all the joints and crevices of my cages with sweet oil before I put up my birds, using a large camel-hair brush, and working it into the joints with a thin knife. I also pour oil into the nest boxes before they are used, allowing the oil to run into the joints. I repeat the process between every brood of birds, and carefully watch for the white powdery look which announces the presence of these pests, and brush the place over with oil. If they appear in a nest, a fresh one must be made as I have explained.”

On the fourth morning will in all probability be found another egg added to the number, and the hen will at once begin to sit, seldom leaving her nest except to feed, and that not often, as the cock, if he be a dutiful husband, will supply all her wants. The egg and hemp seed must now be discontinued. The breeder can satisfy himself in a few days as to whether there be any vitality in the eggs by holding them up to the light, when the blood vessels can be distinctly traced, and the egg will be observed to be semi-opaque, while in a day or two longer it will become perfectly so. Such are said to be “full” eggs. Others are worthless; and if at the expiration of a week they are still transparent, they may be at once removed, as it is useless to distress the hen by allowing her to sit them out, unless her services may be required as a nurse for the progeny of some other bird whose ideas of maternal duties are not of a very clear nature, and which is expected to chip on or about the same date as the other.

On the morning of the thirteenth day following that on which the bird began to sit, the young ones will chip—that is, supposing she lay her fourth egg on Wednesday morning, and at once begins to sit closely, they will chip on the following Tuesday week; and in anticipation of this interesting occasion, have in readiness a hard-boiled egg, and if procurable a nice bunch of chickweed, or, better still, lettuce. Pass a small portion of the yolk through the perforated zinc egg box, and add a little

crushed hemp seed, mixing the whole and chopping it very fine. After the first day or two the white may be added to the yolk. Place this mixture in one of the egg tins in the cage, suspending it in the front near one of the perches by weaving in a piece of wire crossways, on which it will hang by a couple of little hooks attached to it. If placed in the door the hand need never pass inside the cage at all, as the tin will always come outside by the opening of the door. Stand the green food in a small jar of water on the bottom of the cage. The old birds will at once commence feeding their infant brood, an operation which they will carry on at short intervals till they can perform that necessary act for themselves, which will be in about three weeks, more or less according to the attention which has been bestowed on them by their parents.

There is a great diversity of opinion as to the use of hemp seed as a food for the Canary. One of our most eminent breeders and most successful exhibitors, whose buffet is adorned with more than one silver cup won at our All-England exhibitions, is very much prejudiced against it. He denounces it in very strong terms. I shall not soon forget his raising himself from a reclining position in his easy chair in his drawing-room at his hotel in Sunderland, and while taking his cigar from his mouth not to intercept the utterance of so important a maxim, he gave me a smart slap on the knee as if to give still greater emphasis, and said, "Blakston, don't let your birds see hemp seed!" On the other hand, one of the breeders in this district brings up more young birds on it, and nothing else, than others who discountenance its use. Each breeder speaks most highly of that food which he has found most useful. One man condemns groundsel as green food, another uses nothing else, and the same remark applies to each and all of the various items which compose the bill of fare in the Canary room. This diversity of opinion must in the majority of cases result from pure ignorance, connecting certain results with certain causes, without thought as to the conditions which may have induced them. The lessons of our breeding season will teach an intelligent man more than he will learn from listening a whole lifetime to the nonsense preached by a certain school.—W. A. BLAKSTON.

AN EASY MODE OF PRACTISING ARTIFICIAL SWARMING WITH MOVEABLE COMB HIVES.

SOME of your readers may be interested in a method of swarming which I have devised, and successfully practised for the last few years.

My queens have their wings clipped, and the hives are set low, with a moveable board, one end of which rests upon the ground, while the other slants against the alighting board of the hive. When swarms may be expected, the hives for their reception are placed near the full stocks, with frames, &c., all ready for the use of the swarms. As soon as a swarm begins to issue, the apiarian watches for the queen, which will soon be found on the ground in front of the hive, vainly endeavouring to join her emigrating family. Gently seizing her by the wings or upper part of her body, he places her in a wire cage, paper cone, or any convenient receptacle. In a few minutes the bees, missing her, begin to return to the parent stock, which should now be removed from its stand, and the new hive put in its place. As soon as the bees begin to enter, their queen should be liberated at its mouth, and the bees compelled to go in as quickly as possible, when it should be placed where it is to remain during the season, and the old hive returned to its former position. If the hives in the apiary resemble each other, and are not placed too near to each other, there will be no necessity of removing the swarming stock from its place. When the bees begin to return, a sheet may be thrown over it to conceal it from them, and the new hive, with the cage containing the queen, may be placed upon or close to the old one, to be removed as soon as the bees are well hived. Should the swarm issue while no one is watching the apiary, the bees will return, and the queen will soon join them by crawling up the sloping board to the entrance of the hive.

Natural swarming may in this way be safely and easily practised in a large apiary without any fear of the swarms eloping, with little risk of different swarms uniting while on the wing, and without any necessity for ladders, saws, &c., or any of the perplexities with which some of your readers are doubtless only too familiar. The bee-keeper may thus, without any drawback, enjoy all the pleasing excitement of the swarming season. Any one able to distinguish the queen, and to put her in a cage,

may in the absence of the apiarian, easily manage the whole affair, removing the sheet from the old stock as soon as the bees have entered the new hive.—L. L. LANGSTROTH, *Orford, Butler Co., Ohio.*

FEEDING BEES.

I HAVE lost many stocks through insufficiency of food in the winter. Either I do not feed them with the proper mixture, or the bees do not get at it in the best manner. Is it advisable to put the food inside the hives? I have done so, because in the winter time it is not policy to disturb the bees or induce them to come out into the cold to obtain it.

Will wheat flour do as well as rye meal to provide pollen for the bees in the spring? I have tried the former, and find it will not answer.—C. B.

If you give your bees a sufficient quantity of food in October in the manner and of the kind described in pages 72 and 86 of "The Gardener's Almanack," they will do just as well on artificial food as on honey. They should, however, never be fed in winter. We have kept twenty-five stocks through the past winter on artificial food without losing one, and do not believe that they possessed on an average 1 lb. of honey to each stock.

Bees can always get sufficient pollen in this climate at all seasons whenever they are able to fly out. We therefore consider both wheat flour and rye meal worthless as substitutes for pollen in England, however valuable they may be in Germany.

OUR LETTER BOX.

DUCKS' EGGS FOR HATCHING (W. D. A.).—Your eggs will be useless; it is necessary for breeding purposes that the Ducks should be in water now and then. It is not required often.

BRABMA POOTRA CHICKENS' TWISTED WINGS (L. B.).—Your food is very good, add thereto some meat, cooked and chopped fine, and bread and milk, any other change will be beneficial. It is impossible to say how many of your chickens will be fit for exhibition; but if you have two out of six you will be favoured. The Dark Brahma chickens hatched the end of March will be fit to show at the end of July. Fowls that belong to large breeds, and are well managed, and have never had a check, should at six months old, weigh 6 lbs. Twisted wings are caused by contraction of the last joint of the wing, which draws the end feathers of the flight under the others, through which they pass and project.

SILVER-PENCILED HAMBURGHS (S. E. T. F.).—It is impossible you can be correct, you might as well expect them to remain small chickens always, and to cease growing, as to attain the age of twelve months without laying. They certainly lay, and their eggs are either eaten, or they eat them.

CHECKING THE GROWTH OF CHICKENS (L. S. D.).—We know no means of checking the growth of chickens without injury to the birds. Exposure to cold, deficiency of food, or want of quality in it, all check growth. Give your fowls some bricklayers' rubbish.

EGGS WITH THICKENED SKINS (A. I. P.).—Your eggs want moistening before the hatching time comes. They should be wetted every day for five or six days before hatching. The second skin is merely the lining membrane, which hardens from heat and drought, and which the chicken cannot pierce. If the eggs were wetted, this membrane would be soft and easily penetrated.

HOUZAN CHICKENS (J. C.).—Houzan chickens require no particular food or treatment. Feed them as you would others.

MIS-SHAPED EGGS (Osborne).—Your statement is a remarkable one. There is little doubt that purgative medicines would restore her laying properties; but you should save and preserve the very curious abortions you mention.

FOOD FOR DUCKS (J. W. E.).—We cannot guess at the food, that is required by six Rouen Ducks, having a grass run. The best way is to feed them yourself for two or three days. Worms given in very large quantities are bad food, and frequently kill Ducks.

INDIAN GAME FOWLS' PLUMAGE (Norrie).—The Indian Game are smaller than the English, and much more brilliant in colour. They differ in the spur, comb, and gill. On the hackles and saddles every feather has a tip of "light" at the extremity.

COCHIN-CHINA COCK'S HEAD SWOLLEN (C. L.).—Wash with a strong solution of alum; purge freely with castor oil, and feed entirely on bread and ale. We know of no better treatment.

SIX OF GUINEA FOWLS (A Constant Subscriber).—Only the hen utters the peculiar "cock-clark" cry. The male utters no other cry than a wailing whistle.

ANNIE AND DORA are informed that we will find next week, if possible, "A children's corner" in the Journal, for "the verses papa has made about one of their lively hens, to amuse them, and for their instruction too, he says, and which verses they think (and so we think) might amuse some other children as well, who, like themselves, are fond of poultry."

ARTIFICIAL SWARMING (Carotus).—Artificial swarming, when attempted by an unpractised hand, possessed only of common hives, is so uncertain in its results, that we hardly like to advise it, nor is it even certain that it will prevent natural swarming. If you decide on trying the experiment, the stock will probably not require a super at all, certainly not directly afterwards. Your bees may be very strong and very busy, but they are not likely to take to a super so early in the season. Bees obtain honey from all the bushes and trees you mention.

BEES FALLING (A. F. Newman).—Your bees which feed freely, but drop near the hive, seem to be suffering from either dysentery or dropsy. If from the former, this fine weather ought speedily to restore them; if from the latter, we know of but one mode of cure, and that applicable only to stocks in moveable comb hives. Write again if the disease does not abate, and state what kind of hives you use. Bees can now maintain themselves, and need not be fed.

From observations taken near London during the last forty-one years, the average day temperature of the week is 58.5°; and its night temperature 36.9°. The greatest heat was 77°, on the 19th, 1854; and the lowest cold 20°, on the 19th, 1852. The greatest fall of rain was 0.56 inch.

TREES FOR SINGLE SPECIMEN IN EXPOSED PLACES.

ALTHOUGH general lists of shrubs and trees, as well as of other plants, are plentiful enough, yet selections available for special purposes are by no means so frequently given as they ought to be. True there is a long array of ornamental shrubs and trees, and hardy climbers are numerous enough, and not always easy to select from, but there is one class of trees and shrubs not over-numerous—namely, those well adapted to withstand

the storms incidental to a high and exposed situation, or to stand out singly as individual objects, and such of them as we have are not always of the description we want.

If shelter or appearance be the aim of the planter, it is better at once to choose something likely to insure the desired result, however common the plant may be, than to employ an exotic, but improper plant, that is thought to be rare and choice, with the certainty of seeing it drag on a wretched existence.

Could we but be led to think it, our own country possesses trees of extraordinary beauty and utility, our bluffs and headlands being, perhaps, as well clothed naturally as those of any other, and in these cases Nature selects the best and most suitable for each of her works. The Alder and Sallow occupy the marsh, the sides of brooks, and similar places, but are not often met with on the crests of hills 300 or 400 feet above the level of the adjoining country. On such elevations a class of plants especially adapted to high grounds is met with, and some of them are of especial beauty and merit. As it is often desirable to plant a solitary tree in such a position, the class best suited for that purpose deserves to have special consideration.

Assuming, therefore, that it is advisable to plant only a very small number of trees in such a situation, or it may be only single specimens at particular places, the list suitable for the purpose is a very limited one, and the trees constituting it will most conveniently be dealt with separately in the remarks which I purpose offering.

Yew.—This unquestionably stands first for the purposes referred to, not only from its great hardiness and its withstanding all the storms to which our island is subject, but also on account of its beauty and the associations connected with the tree. Yew trees frowning over chalk cliffs or precipitous rocks form a most important feature in the landscape of many districts, and the period for which the tree has done duty may often be computed by centuries. Its sturdy limbs seem to bid defiance to the violence of any gale, and, what is equally important, the growth on the windward side is scarcely less than that on the sheltered one. A slight inclination in one direction may be given to the stem or bole, if the tree has one: but even this is not always in the direction of the wind, and the Yew stands out boldly to the blast, presenting that unchanging appearance which possibly may have had much to do with securing it a place in our churchyards, where so many noble specimens of it exist. The Yew is also more accommodating than most trees, for, although it is often met with

in the most exposed positions, it is also not unfrequently seen luxuriating beneath the shade of other trees, where many plants would fail to live, and still exhibiting that sombre dark green appearance which is peculiarly its own. It is, however, mostly where it stands out in bold relief to the landscape that this fine tree appears in all its glory; its wide-spread limbs thickly clothed with a foliage which braves all weathers, and the strength and elasticity of its timber setting at defiance, or nearly so, all the vicissitudes of our climate. Even to time the Yew only yields after everything else has done so, it being about our longest-lived tree. Possibly when our collectors have exhausted both hemispheres of their arboreal treasures we shall then discover that we have some of the noblest of Nature's productions at home; for the Yew, the Scotch Fir, and the Beech, the Oak, and several other deciduous trees, together with the Holly as an evergreen, are not easily excelled.

The Yew will grow in most situations, but it delights in a dry stony soil, though it will make greater progress for a time in rich garden soil. It has also the good quality of transplanting well, if it has been transplanted before; but plants from seed self-sown in a shady wood, if 3 or 4 feet high, do badly when at once removed to an exposed place, and, indeed, are apt to die. Those, however, which have been inured to transplantation are but little affected by the operation. Staking, which is generally needed by newly-planted trees, is but rarely required by the Yew, and whether planted singly or in a group it may with perfect safety be placed to the windward of almost everything else with a fair prospect of its doing well. When planted in situations to which cattle have access, means must be taken to prevent their approaching it, as it is highly poisonous to them. Rabbits seem to be endowed with a greater perception of what is good for them than larger animals, for they do not meddle much with poisonous plants, but where they are numerous the Yew does not escape; at least, small plants suffer; but they are not so fond of this tree as of many others. In most cases, however, where this plant exists near a gateway leading to some pasture field it is advisable to make sure of that gate being always shut, or, by some slight protection to keep cattle and horses from partaking of it.

The Yew is of easy culture, and adapts itself well to most situations, except where the ground is either a stiff clay or very moist, but it grows best in the soils and situations where it is usually found wild.

Oak.—Like the Yew, this noble tree succeeds in the dense forest as well as when growing singly in an exposed position, but if the elevation is very considerable the tree in this case is more stunted in its growth than when otherwise situated. Planted singly in a favourable spot its powers of resisting the elements are very remarkable, and the country can boast of many fine old Oaks standing in such a position, and evidently capable of enduring for many years yet. I remember seeing in a hedgerow in Buckinghamshire an Oak that was very nearly 28 feet in circumference at about 3 feet from the ground, and that appeared likely to last for a century or more without

change. As a tree capable of withstanding the rude blast the Oak may with advantage be planted in most soils not of too peaty a nature, but even in such it will grow, although it succeeds better in a rather calcareous clay not too much charged with water. The limbs of the Oak rarely suffer from the wind, but the bole may do so a little, especially if the tree has been sheltered in the earlier part of its growth, and then exposed. Generally speaking, however, the Oak assumes that fine spread of head which renders it so prominent a feature in some landscapes that certain Oaks may be pointed to as landmarks. The Oak also looks well when in a state of decay; in fact, the painter would consider it in its glory when the tips of its branches were dead and dying.

The Oak transplants tolerably well; rabbits, where they are numerous, destroy small trees, and I have known mice in severe winters gnaw through the young plants at the collar, but the tree resists all attacks, even those of time, better than other rees.

CEDAR OF LEBANON.—The frost of January, 1867, having proved that many new trees expected to be hardy are not so, the rage for these has been somewhat checked, and the Cedar of Lebanon has maintained its place as being one of the most valuable ornamental trees we possess. I am not sure whether any of the Conifers imported during the present century (and their number is very great), approaches it in point of beauty and general adaptability; for we have no proof that the species introduced during that period will prove to be so hardy, and possessed of constitutions capable of withstanding the changes of our climate so well as this fine Cedar, which may now be said to be almost naturalised. The many large specimens gracing the lawns of some of our noblest mansions attest its enduring powers, as well as its capacity to become a large fine tree. Witness the fine trees on the lawn in front of Chiswick House, and many other places possess equally fine trees. In the garden of a farm house only a short distance from Maidstone, are two noble trees equalling in size many of the finest Oaks in the district, the bole of one of them appearing to contain from 70 to 100 cubic feet of timber, and the trees being likely to last some centuries yet. The cutting away of the lower branches some years ago, for the benefit of the under crops, has injured the appearance of the tree very much, as the Cedar usually branches close to the ground; and if the lower branches do die off, which is sometimes the case with very aged trees, the tier above them hangs down so as to touch the ground.

The Cedar likes a dry situation, or rather one in which stone abounds, and its capabilities of withstanding weather of all kinds are so well known as to require no comment. It is also well suited for planting singly, and looks better so planted than in a mixed forest. It may also be transplanted more successfully than some kinds of Conifers, and is rarely subject to any mishap. A very heavy fall of snow may break some of the limbs that are too heavily laden; but this is not of frequent occurrence. Winds rarely affect it, and when it occupies an elevated position its windward side presents much the same bold outline as its other side.

BIRCH.—The beauties of this tree are not half so well acknowledged as they ought to be. Its smooth silvery bark, now and then shedding an outer coating like the unfolding of a roll, with the numerous elastic twigs growing or rather hanging in graceful profusion all over an umbrageous head, and the whole clothed with pleasingly-shaped leaves, claim for the Birch a high position among ornamental trees. It is so different from the other trees which we possess, that no one can mistake the Birch for anything else than what it is, which is not always the case with other deciduous trees when viewed in winter from a short distance off. The Birch never attains the dimensions of some of our native trees, but it is unquestionably the hardiest we possess, as in one or other of its forms it is found ascending the highest mountains, as well in other countries as in this, diminishing in size according to altitude, and disappearing where only some insignificant member of the vegetable kingdom is able to exist. This proves the Birch to be a mountain tree, and its appearance in such a position is in an eminent degree ornamental. Either singly or in groups it forms a fine object, and like the Oak it sends its limbs out on the side exposed to the wind, just as much as on that which is sheltered; but the bole or stem often leans from the blast, yet its doing so adds, perhaps, to the beauty of the tree. The Birch thrives in a soil more or less inclining to peat, but does not object to moisture, is very accommodating, and succeeds in most situations, but is most at home on the steep side of a mountain dingle, and

there its feathery appearance when loaded with hoar frost is most elegant. On the level or highly-kept lawn it is also ornamental, and as a single tree it is highly deserving a place.—J. ROBSON.

(To be continued.)

CULTURE OF AURICULAS.

AN ardent and successful grower of this beautiful, and, in my opinion, too much neglected flower, I read with pleasure the article by "D." of Deal, in THE JOURNAL OF HORTICULTURE lately. A frame containing several hundreds of well-grown plants in full bloom is a sight worth going miles to see, and yet many a gardener and amateur who are enthusiastic about other plants, are in total ignorance of the perfection to which the stage Auricula has now been brought. What can be more exquisite, besides the perfume, than the contrast of colours in the grey, green, and white edges, and selfs? I confess to having had a passion for the Auricula ever since I was a boy, when I grew the border flowers of which I had many varieties, and I have never yet forgot the time, now nearly thirty years ago, when I first saw a few stage plants.

It is now six years since I invested in a dozen plants of the easiest-grown stage sorts, and for the first year or so felt rather afraid lest I should not be able to keep them. In place of that, however, they have thriven with me far beyond my expectation; and my stock, to which I have always been occasionally adding, at present consists of about four hundred plants, comprising eighty varieties of all the leading sorts. I experience no difficulty whatever in growing them, scarcely ever losing a plant, and the health and vigour of the whole stock are the admiration of every one who sees them.

The plants are grown in a frame very steep in the pitch, raised on stone pillars about 8 or 9 inches above the ground, with a step-by-step stage all open below, and placed about 10 inches from the glass. The sashes are linged at the top, and when open are kept up by a rod. There is a moveable glazed sash about 8 or 9 inches wide, hung on a pivot at each end, at top and bottom to admit air. The back and sides of the frame are of wood, and it is set about 6 feet from the back of a south wall, and facing the north. The pots are not plunged, but simply placed on the shelves, and the only extra protection the plants receive is with mats in severe frost in winter, or after they begin to grow in spring. The sashes are never taken off the plants all the season.

The greatest enemy to the Auricula is damp, and the plants can scarcely be kept too dry in the winter months. Worms, too, are very injurious, as they destroy the drainage. The simplest way, however, to get rid of them is to roast all the materials used in potting.

My treatment is as follows:—The blooming plants are grown in from 4 to 6-inch pots, according to size and habit. During open weather, about the first week in February, or as soon as the plants are observed to have started into growth, scrape off about from three-quarters to one inch of the surface of the soil, taking care at the same time not to disturb any of the roots, and top-dress them with a mixture of one-half well-rotted sheep dung, and the other half leaf mould, with sufficient silver sand added to make it porous, all having previously been put through a fine sieve. Give the plants a good watering, keep the pots clean, and stir the surface occasionally. They now require a considerable quantity of water, but it must be given cautiously, especially if the weather be frosty, and the air-giving must be regulated so as not to expose them to cutting winds. No water should now be allowed to touch the leaves, as it spoils the fine powdery appearance of the plants, and the best way to water them is with a low flat pan, having a long bent spout. If seed is wanted the flowers require to be impregnated when in full bloom, and this is easily done with a camel's-hair brush.

As soon as the blooming is over, the plants go to rest for a little. They should now have all the air possible, all the flower stalks should be removed if seed is not wanted, and in hot weather a gentle syringing should be given overhead two or three times a week. After a little the plants start again into growth, and the offsets begin to push vigorously.

The first week in August is the time I always repot, though I believe growers in the south do so immediately after the blooming is over. A mixture, which has been previously passed through a half-inch sieve, consisting of one half loam and the other half of equal parts of leaf mould, peat, and cow dung well rotted, and with a sufficient quantity of silver sand

added to keep it porous, is now prepared. The plant is taken out of the pot, and the old soil shaken clean away; any offsets are taken off with a sharp flat knife, and the cut parts rubbed over with a little powdered charcoal to stop the bleeding. All decayed parts are cut off, and any long roots shortened. A clean pot is taken, an oyster shell with the hollow inverted is placed over the hole in the bottom, a little moss is then put over it, and above the moss a handful of the rough riddings of the leaf mould. The soil is then put in, and around the roots, and the plant pressed in firmly with the hand, but so as to keep all the leaves clear of the soil. A good watering is then given, and if the weather is hot a slight damping with the syringe, and the frame is kept close for eight days till the plants begin to root. After that they should have all the air possible, and water when necessary till frost comes.

During the winter months the plants go to rest, and should have no more water than is sufficient to keep them from flagging. A yellow leaf should never be allowed to remain for a day on any plant, but must be immediately picked off.

There are some very fine varieties which are not yet sent out, but the cream of those generally grown in my opinion, say six of each, is as follows:—

Grey Edges.—Chapman's Maria, Chapman's Sophia, Headley's George Lightbody, Headley's Charles Edward Brown, Lightbody's Robert Trail, Cheetham's Lancashire Hero. *Green Edges*.—Eeston's Apollo, Dickson's Duke of Cambridge, Dickson's Duke of Wellington, Leigh's Colonel Taylor, Lightbody's Sir John Moore, Smith's Lycurgus. *White Edges*.—Hepworth's True Briton, Lee's Bright Venus, Trail's White Rival, Campbell's Robert Burns, Lightbody's Countess of Dunmore, Lowe's Maggie Lauder. *Sells*.—Lightbody's Lord Clyde, Lightbody's Meteor Flag, Smith's Formosa, Smith's Mrs. Smith, Martin's Eclipse, Martin's Mrs. Sturrock.

There are many others equally good, but a great step has of late years been made in some of the new plants, which will be let out by-and-by, and are exquisitely beautiful.—J. M.

BUSH FRUIT TREES.

I HAVE much pleasure in giving the information which Mr. Rivers is pleased to consider will "add much to the value of my communication," (see page 198).

I live two miles south of Lincoln, on a gentle slope at the foot of the Cross Cliff Hills. The soil in my orchard varies from 2 to 4 feet deep, and from a light sandy loam to a stiff clay, the greater portion being a moderately strong loam, just what one would desire for fruit trees. But this land has been artificially prepared in various portions, by clay and finely comminuted chalkstone (containing 98 per cent. of carbonate of lime), scrapings of limestone roads, &c., to suit the various fruits it is intended to produce. It has, moreover, been enriched, though all newly-trenched grass land, with good manure at the rate of 45 tons per acre, and 11 cwt. of half-inch bones. A long strip thus treated has been divided into nine parts and top-dressed with different chemicals.

The subsoil is gravel and clay well drained, although, being on a slope there is never any stagnant water, which, no matter how great the rainfall, percolates rapidly to the river. Taking advantage of the fall, I have made in the upper part a small pond, always full, whence the water is conducted in pipes into large oak casks sunk deep in the ground and covered over. Communicating with each is a 3-inch pipe through which the suction-hose is dropped down, and a Californian forcing-engine rapidly clears the aphides from the trees and waters them effectually as well. The supply from the pond is regulated by a screw sluice-gate. Thus, nearly all my trees can be easily syringed and watered.

Reverting to the subject of lifting trees, I must first thank Mr. Rivers for his explanation, and assure him that I never for a moment considered him capable of intentional "misrepresentation;" but that his bare statement, that "an active man can lift one hundred in a day," is calculated to mislead without explanation. Now, let us look at it and see how far we can agree. Mr. Rivers's man with a "treddle" spade and unlimited opportunity for back-stretching, can lift 120 per day; but Mr. Rivers is confident that a man with such a spade would do three times the work that the same man could do with an ordinary garden spade. Hence a man with a garden spade would lift forty per day. Now, my two men thus armed lifted one hundred per day between them, and, consequently, did half a day's work more than, according to Mr. Rivers, I had a

right to expect; but I am satisfied that, no matter what spade be used, two men can do such work proportionately quicker than one. Trees must be replaced at measured distances in straight lines, one holds the tree whilst the other cuts the roots, for at the first lifting of any tree this must be done, though it may not be necessary afterwards, and having a man on each side of the tree there is less moving about and less liability of damaging the neighbouring plants.

Mr. Rivers's explanation hinges altogether on the kind of spade, of which, I trust, he will kindly send me a specimen, as requested in a private note, for it will well pay its expenses. Mr. Rivers does not mention the kind of soil on which he experimented. It could hardly be more easy to work than mine, which required no scraping of the spade—an item that must much increase the time expended; and, moreover, he appears to have timed his man on one tree only, whereas I timed my two men by the hundred; first when they did not know, and the next day when they did, the result being the same. After all was over I read the passage from the "Miniature Fruit Garden," and they expressed a desire to see one of Mr. Rivers's men, and now they have heard his explanation they are as anxious to see his spade.

I am obliged to Mr. Rivers for an account of his plantations, and the gleam of comfort (?) he inspires by an account of the failure of his crops. Certainly it is a melancholy sort of satisfaction when one has no crop, to know that even Mr. Rivers himself has failed, and been beaten by our common enemy—frost; but I really do not require any comfort, feeling confident that bush fruit trees are "the best thing out," and must prove a success one year with another. But surely Mr. Rivers's plantation of Cox's Orange Pippins, which will stand eight years 3 feet apart every way, is more curious than desirable, taking quality, quantity, and early productiveness as the desiderata. I conceive that as long as a tree bears plenty of good fruit, and makes short-jointed wood full of fruit spurs, that the bigger one grows the tree the better. A well-managed hush 6 or 7 feet high produces something worth gathering, and I cannot help thinking, had Mr. Rivers allowed his trees to make more wood and thinned them out, that he would have realised more fruit in the same time off the same ground, and planted a similar piece as well; and I hope he will kindly tell us whether he advocates dwarfing to such an extent, as a means of obtaining the most good fruit on a given space, or whether it is merely a horticultural triumph, and an illustration of what can be done in the way of a miniature fruit garden.—G. C. E.

NEPETA TEUCRIIFOLIA, VIOLA CORNUTA, AND LOBELIA ERINUS SPECIOSA.

WHETHER *Nepeta teucrifolia* become a rival to *Viola cornuta* or not, as suggested in page 203, will remain to be proved, but it is well worthy of attention on its own account, and probably if we have a very dry summer, and beginning, as appears likely, early in the season, I fear many who have so strongly advocated the claims of *Viola cornuta* will be willing to turn round and admit themselves mistaken about its qualifications for withstanding dry weather. I do not wish to try to dishearten those who intend planting this useful bedder, but would advise their adopting a plan I noticed attended with the best possible results—namely, this *Viola* was planted alternately with *Lobelia erinus speciosa*; and as this mixture was all that could be desired last year, in which there was no lack of moisture during the early summer months, it is more likely to be of service in a season when, perhaps, we may be suffering from a contrary state of things; for in a dry warm season the *Lobelia* will prosper, but I have little hopes of the *Viola* doing so. In the well-kept garden at Preston Hall the mixture of the two was well carried out last year by Mr. Bradley, the gardener there, and very effective the lines of it were, and their beauty was long maintained.

The *Nepeta* will, I think, hardly come into competition with the above, being of taller growth, and in colour more of a lavender; it is, however, a plant of much merit, and its not being particular as to situation is a great point in its favour. It is also quite hardy, or nearly so, and is possibly capable of improvement. It would be a great boon to many, who are at a loss how to provide the numerous bedding plants which they require, to be able to press a goodly number of hardy ones into their service. I hope to see this done in time, and trust that many plants not yet thought of may be so much improved in the hybridiser's hands as to meet the requirements of the

day, of which a prolonged flowering is one of the greatest. That the *Nepeta* possesses this property is well known, but the number of its flowers may, perhaps, be increased, and their colour and quality improved. As it is, I certainly can, from a long acquaintance with it, recommend it for a line or edging near shrubs, or in some place where what may be called second-class plants are brought into use. For the geometric garden, where the highest colours only are admissible, I would hardly recommend it; but I have no hesitation in advising the mixture of *Viola cornuta* and the *Lobelia* for any situation in which the latter has hitherto been employed; and if the *Viola* were planted at once an earlier bloom would be secured than would be the case with the *Lobelia* alone, and most likely the flowering would also be longer maintained.—J. ROBSON.

MR. PERRY'S SEEDLING VERBENAS.

WHEN at the Birmingham Rose Show last year I took the opportunity of visiting Castle Bromwich to see Mr. Perry's seedling Verbenas, and as he had an unusually fine lot I send you a few notes of them. I assisted him in making a selection, and it was with considerable regret we threw aside a large number of really good flowers, so determined was Mr. Perry on sending out only the very best of his seedlings. Two span-roofed houses were devoted entirely to proving seedlings of 1866, and a few of the best sorts already out; and from these his supply of seed for the following year is obtained. His yearlings were all blooming in store pots in frames, and as soon as anything good is recognised it is marked for proving next year, and all not up to the mark are thrown away.

I regard Mr. Perry as the first Verbena-raiser of the day, for the greater portion of the best kinds now in cultivation have been raised by him; and the set to be sent out this spring would alone place him in the foremost rank of raisers if he had never sent out a Verbena before. They will probably consist of—

Miss Turner.—White, with very large pale rose centre, and very fine pip and truss.

Samuel Moreton.—Shaded rosy blush, with large dark centre. Very fine pip and truss, and very distinct.

Hercules.—Rich rosy carmine with dark centre; very fine form and large. A beautiful flower.

Emma Perry.—Blush white, with large dark rosy red centre; very fine pip and truss.

James Birkbeck.—Rich glowing light rosy scarlet, with light eye. A very superb variety both in pip and truss.

Mrs. Mole.—A peculiar lavender-tinted lilac, with large and finely formed pip and truss. Very fine indeed.

Interesting.—Pale scarlet, with distinct white eye and finely formed pip and truss.

Shirley Hibberd.—Intense dark violet, with small white eye, A rich-looking flower of great substance and fine form.

G. P. Tye.—Lighter than Mrs. Turner, with a deeper-coloured centre. A dwarf-growing kind, with very fine pip and truss.

John Wilson.—Rosy carmine, with a violet-tinted centre. Very fine truss and habit.

J. C. Ward.—Light purple, with light eye. Fine form and truss.

James Day.—Shaded light violet, with white eye. Fine truss.

Little Clara.—Shaded pink, with dark carmine centre. Fine form and fine truss.

I have yet to speak of the finest Verbena of all—*Mrs. Perry*, rich blue-purple, with large light eye, and very fine form. This is a superb kind, but it will probably be held over for another year. Several seedlings of last year have still to be proved, and there may be some fine kinds amongst them, but it will be difficult to beat those we selected.

I also give you the following list of the best of the older kinds I saw in Mr. Perry's houses. These are all exhibition flowers, and are grown for that purpose and for producing seeds.

Cleopatra.—Rich dark rose, with white eye. Extra fine.

Delicata.—Pale rosy pink, with light eye. Fine truss.

Harry Law.—Distinct rosy lilac, with large white eye. Very fine pip, and large truss.

William Dean.—Rich violet, with dark violet centre and large clear white eye, finely formed pip and truss. It certainly is a very fine variety.

Indispensable.—Shaded light purple, with well-formed truss.

Esquisite.—Bright reddish pink, with large lemon eye. Fine pip.

Snowball.—The best exhibiting white, but not a pure white.

Nemesis (George Smith).—Rich light scarlet, with small lemon eye. Fine truss.

Auricula.—Rich shaded purple, with large light eye.

Leah.—Pale shaded rose, with large dark centre and large white eye. Very fine pip and truss.

Firefly (Miller).—Lighter than Mazeppa. Very fine pip and truss.

Pink Perfection.—Bright reddish pink, with light eye. A most valuable kind for pot culture, beds, or cut blooms.

Majolica.—Shaded pale rose, with large white eye surrounded by a dark ring. Very large pip and truss.

Wonderful.—Shaded crimson, with white eye. Extra fine in pip and truss.

Meteor.—Rich glowing scarlet, with lemon eye. Small but well-formed truss.

Cato (George Smith).—Blush, shaded and marked with pink; dark eye. A good exhibition kind.

Rose Imperial (Boucharlat).—A glowing rosy pink, with large scarlet centre. Very fine truss.

Mrs. Turner.—Blush, shaded with pink, with a large, deep rosy pink centre. Fine.

Mauve Queen.—Shaded mauve and lilac, with a large light eye. Very distinct.

Charles Perry.—Rosy lilac, with a large dark centre and light eye. Very fine truss, and compact habit.

Champion.—Rich crimson, with small dark centre and yellow eye. Very fine.

Mazeppa.—Brilliant deep orange scarlet, with clear white eye; large pip and truss. Extra fine.

Harry Turner.—Shaded blush and lavender, with a bright centre, and very large well-shaped truss.

Magnificans (Boucharlat).—Lilac shaded with pink, large dark centre. Very large truss, and a fine back-row flower.

Apollo (Smith's).—Blush shaded with pink, and dark centre. Very large truss.

Lilac Queen.—Distinct from Mauve Queen, and very distinctly marked. Very fine truss.

Those to which no raiser's name is attached have been raised by Mr. Perry. There are also others of his raising, such as Charles Turner, Mrs. Dean, James Walton, and others, still very fine kinds. All that I have described I saw in bloom at his place, and others bloomed after I had a second opportunity of seeing his superb collection. He is a first-class grower, and aims at moderate-sized plants in small pots, and the plants are full of health and vigour; and what glorious trusses he obtains those who exhibit against him know full well.—WILLIAM DEAN, Bradford Nursery, Shipley.

TOBACCO LIQUOR FOR DESTROYING INSECTS.

I HAVE no doubt that many will agree with me that tobacco smoke is ineffectual for destroying black and white thrips, and also some species of aphids, especially the yellow aphids often found on Orchids. Three-quarters of a pint of tobacco liquor when obtained from a reliable vendor to one gallon of water for aphids, and one pint to a gallon of water for thrips, are good proportions. The mixture is to be syringed all over the plant or tree in the evening. We have tried the above proportions upon Vines, Peach trees, Orchids, and a variety of stove plants, as well as bedding plants of various sorts, and have found it quite effectual without causing the slightest injury to the foliage. If any insects escape the first syringing give another the following morning, and death is certain.

Tobacco liquor has other advantages. When only a few plants are infested with insects they can be syringed without the trouble and expense of fumigating a whole house.—W. CLARK, *Reby Gardens*.

PROPAGATION AND FAILURE OF CENTAUREA CANDIDISSIMA.

I WOULD advise cultivators of this *Centaurea* to examine their plants minutely this season, and I think they will find them attacked by grubs. Such was the case here last year, and they have again made their appearance upon old plants that have been in the ground all the winter. The plants in question had every appearance of those described by Mr. Robson (page 254). I have enclosed a grub for your inspection.

Those who wish to preserve old plants of *Centaurea candi-*

dissima, I would advise to select a few of the strongest plants any time in March or April, and to repot them in 12-inch pots. These plants can be used for decorating the flower garden by plunging the pots in the soil, and when taken up in the autumn are invaluable for decorating the conservatory in winter, and likewise useful to those who choose to propagate the plant in spring.

There are various opinions respecting the propagation of the *Centaurea*. Some are in favour of cool treatment, others are for spring propagation. We are all aiming at one point—that is, good strong plants for bedding-out early in the spring; and for this I can with confidence recommend autumn for the operation, and also a good bottom heat for the cuttings. Plants thus treated will be double the size of spring-struck cuttings. We find no difficulty in propagating and growing this *Centaurea*, and think it far superior to *Ciucraria maritima*.—W. CLARK, *Ruby Gardens*.

[The grub, though in a chip box, was smashed by the post-office punch; but we think from the skin that it is the "leather coat," or larva of the daddy longlegs (*Tipula*).—Eps.]

SETTING MUSCAT GRAPE.

HAVING lately observed in your pages a controversy respecting the setting of Muscat Grapes, and as your correspondent "Nexo" seems to think that the remarks made by Mr. Battram are inconsistent with both rule and practice, the following may perhaps help to convince him that setting Muscats in a damp atmosphere can be effected, and that Mr. Battram is not the only one who has met with success.

In one of the vineries at this place there are six rods of Muscat of Alexandria, four of Alicante, one of Ingram's Prolific Muscat, one of Lady Downe's, and one of White Nice. These Vines were wrapped in haybands, and laid along the front of the house until the middle of February, when we were under the necessity of undoing the bands on account of the forwardness of the Vines. At this time the temperature of the house was kept at about 60° at night, on account of a large Fig tree which covers the back wall.

The Vines were syringed twice a-day until they began to show bloom; the syringing was then discontinued, but abundance of moisture was kept in the house by the damping of the border and paths at least four times in the twenty-four hours. This house is very flat, consequently it is always late in the day before any air can be admitted: it is also the furthest house from the boilers of four, two of these being in forcing at the same time, and we could therefore admit no air after 2 P.M. Under these circumstances the above Vines have set as well as some of our Hamburgs which were setting at the same time in other houses. The greater part of the bunches are now thinned out. Ingram's Prolific Muscat is the earliest; Alicante and White Nice are very nearly together; but some of the bunches on the latter are taking the lead for size. Three of them measure respectively 16 inches long by 15 inches across the shoulders, 14 inches by 16, and 13 inches by 12. Muscats of Alexandria come next, and Lady Downe's is scarcely set.—J. TAYLOR, *Foreman, Nineham Park Gardens*.

OLD FAVOURITES.

I HAVE just received THE JOURNAL OF HORTICULTURE for April 2nd, and am reminded that I have lying in my desk a letter addressed to you a week ago, detained through my indisposition, which if not in the words of Mr. T. Williams, yet in the same spirit, expresses my hearty welcome to two letters, "Flowers of Other Days," and "Flowers Lovely Though Common."

To be thus anticipated is a real pleasure, showing that the number of those whose hearts are "affected" in the good cause is increasing. I am also grateful to you for so cordially opening the way for information on the subject, so that the neglected and forgotten may once more shine forth in their native beauty, as they did under the eyes of our grand parents, when in the "quaint parterre" they scented "the sweet Musk Rose."

In one respect I am disappointed. I had hoped to supply Mr. Harpur Crewe with the *Narcissus triandrus* or *cernuus* but Mr. Williams has anticipated me; to communicate is half my pleasure in cultivation, and perennial roots increasing so fast as they do, suggest liberality to our neighbour.

It was with great pleasure I observed that in your Journal

for March 26th, we are promised a further sight of the Orston Vicarage garden, so that we may compare notes with Mr. Mellish, for our borders have presented the same gay flowery appearance since the first week in February, and this will continue till the end of November, although Scarlet Pelargoniums and some other bedding-out plants will only find a place to fill up spaces, and give variety of colour. We are often asked by our neighbours whose borders lie fallow for six months, "How is it that you are never without flowers?" Our invalid friends, too, have been cheered by gifts cut from our early spring flowers, and London homes have been made fragrant with the breath of Primroses and Violets.

I have cultivated an old-fashioned garden for many years in the beautiful valley of the Dove, and in Cheshire; and when we came into Kent, though our garden plot is small, being so near London, where land is too valuable to afford large space for pleasure grounds, we still continued our old custom, and gathered together most of our "flowers of other days," but not without much inquiry, and some disappointment. However, we were fortunate in meeting with a nursery garden of long standing, where the intelligent master still kept up his stock of old-fashioned plants. There with many others I found *Dodecatheon meadia*, *Scilla bifolia*, *Fritillaria meleagris*, which grows wild in Dove meadows, Grape Hyacinths, blue and white, and the singular Fringe Hyacinth, which Mr. Stidolph, of Bromley, our good nursery gardener, says has become exceedingly scarce.

Should you not deem as an intrusion in your pages a few remarks as occasion offers on the cultivation of some of our handsomest wild flowers, I shall be glad to give you my experience, for we have never been without our "English border;" and having myself derived health of body and mind in the pursuit of English botany, and the cultivation of our best flora, I am desirous to interest the young and active of the present generation in the attainment of the same blessings by the same means, for

"Musing in a woodland nook,
Each flower is as an open book."

—ANNA HARRISON.

I AM well pleased to find that your readers are giving more attention to the hardy plants of our cottage gardens.

Your correspondent "H. Harpur Crewe" need not fear that his bulbs of *Triteleia uniflora* will remain dormant. They sometimes rest from being kept too dry. A friend has three pots of bulbs growing in a cold frame with his alpinas; some years since they remained dormant for two years, the third year they grew and flowered very well, and now, although they are growing in the same pots of soil, they are very healthy and promise abundance of flowers.

Ranunculus pyrenaica, the plant your correspondent Mr. Williams so much desires to have, was in my collection last spring; but it was lost by a black snail eating the root in two. As I have never seen it in flower I very much regretted the loss. "The pretty little plant from Lapland," *Cardamine trifoliata*, is eaten up by the same pest, which eats off the roots from the bulbs of one of my favourites, *Scilla praecox*, leaving untouched twelve or fourteen other kinds.

I have two beds of *Narcissus bicolor* just coming into flower. They promise to be, as they have been for some years past, a great ornament to my cottage garden. May your correspondents go on with their notes on our hardy favourites; if they do they will please your readers, and none more so than—RUSTIC ROBIN.

PREPARING LILIES OF THE VALLEY FOR FORCING.

As it may not be very generally known that by a very simple mode of procedure the forcing capabilities of this most deservedly popular plant may be materially enhanced, no excuse will be necessary in introducing a few remarks upon the subject in this Journal, more especially when it is considered that it is next to impossible to have a too large supply of them in flower, from the earliest months of the year onward until it may be possible to gather them from out-door beds. As a British plant, it should be essentially within the province of our craft to push the "Lily of the Valley" to its utmost cultural limits, without the aid or intervention of foreign ingenuity, or even more favourable climate. Yet true it is, nevertheless, that the Dutch, or others, are now making a profit by growing patches

of these suitable for forcing, and then sending them to this country by many tons weight annually, in company with bulbs which we are obliged to look to them for. There are two distinct features in the cultivation of this plant, operating antagonistically to the simple efforts hitherto expended in its culture—namely, a great dislike of being uprooted and separated into smaller portions, which do not very readily attach themselves to the fresh soil; and, when once they have taken possession of the same, such an extraordinary power of multiplication of all parts, that they very quickly become very densely packed together, each thereby neutralising the efforts of the others to attain a fine crown likely to flower in the ensuing spring, and, even should it flower, operating prejudicially as to its fineness. Hence the want of greater success in forcing plants grown after the ordinary method.

With the above suggestions as a basis to our subsequent operations, a piece of ground should be prepared by making a trench $1\frac{1}{2}$ foot in depth, adding abundance of manure, and working it to the necessary space which may be required, according to the quantity needed. When finished, the soil should be trodden firmly over its whole surface. Forming little bundles of from two to five individuals, and with all the roots possible attached and uninjured, dibble the bundles firmly in rows, some 20 inches apart. Fix them firmly in the soil, putting a thick layer of leaf mould over all when finished. With proper attention and keeping them free of weeds, &c., they will be fit for forcing in three years. Hence it will simply be necessary to plant a small space annually, to ensure after the above date a constant succession of excellent patches. A west aspect is the most suitable.—W. EARLEY (in *Journal of Royal Horticultural Society*).

OUR GARDENS.

Among the quiet enjoyments of a country life, there are few deeper or more lasting than that of gardening, to say nothing about its health-giving power and refining influence. But then it must be real gardening—that of digging and planting, sowing, and weeding, and watering. This enjoyment may be gained under various circumstances, for narrow limits do not in any important degree influence the return, some of the smallest gardens giving back the most.

It does not require any large amount of high culture or great physical strength (though both these in their way make work easier and more pleasant, and prevent loss and failure), for the ignorant often grope blindly away from the very end they desire. Not that all loss and failure can be called fruitless; sometimes they lead on to a higher success than might otherwise have been achieved.

It is an enjoyment lessened by no warring element, no class regulations. All may share in it who possess a few feet on the surface of mother earth, and are willing to bring the one thing needed—labour, and without it no garden can long be a pleasant place. So if you have a garden you must work if you have time and taste; if not, you must hire labour, for an ill-kept untidy garden is a constant reproach to ourselves, and an eyesore to our friends. Sometimes it is something more, as when our next neighbour suffered barrowloads of groundsel to seed among her Potatoes during the autumn months and our bit of a garden, standing north-west, received a seven-years benefit.

Yet there is no denying that gardens are a luxury; though we would fain make ourselves believe them a necessity belonging to the rich, those who are rich in means, or strength and time; for though gardens give long vacations during one part of the year, the other part requires incessant work. Nor is the vacation, though a long one, free from anxious forethought, to those who wish to go along with progressing times; and if there is ambition to be foremost, then labour and cost are never counted. Owners of pet villa residences will get up soon and sit up late to work or help on work, in their gardens. Mr. Jones, of Woodside, furnished himself with a good oil lamp for that purpose, and every morning through the dark days of winter, when there was no frost to contend with, might be seen digging or planting by its feeble light hours before his fashionable neighbours thought of their breakfasts. The mayoress of a large town, also used often to boast she did all the work in her not very small garden, even to mowing the grass plots, and clipping the edges; but the light mowing machine was always out of repair, and cost her husband far more than if a man with a scythe had done the work at the rate of half-a-guinea a-time. The large tailor's

scissors, likewise, which she worked with, wore out her gloves, and blistered her fingers; but she had her pleasure and did not mind—a pleasure she often said she would "not exchange for ribbon borders miles long." "What a splendid garden you have!" said a visitor. "Yes," replied the lady spoken to, "we have nearly two acres devoted to Flora's charms, and two men have nothing else to do but attend to her, yet I had more real enjoyment in the little garden I tended the first few years after our marriage. I am fond of outdoor work, yet I never dream of doing anything here." No one ever does where practical gardeners are kept, for of all men they are the sorest about any one intermeddling in their line of business: so it is best, I assure you, to leave them alone to their work; and do not trouble them with questions as to what this is, or what that is, for fear you are answered like the lady who asked her Scotch gardener what kind of seed he was sowing, and received the courteous reply: "Wait, wait, ma'am, and you will see;" or like one I heard of the other day, who, when desired to plant the herbs for kitchen use nearer to the house, and not at the very far extremity of a long garden, replied: "The'd soon be done, for cooks knew the cost of nothing."

But speaking of little gardens belonging to people not ashamed to be seen working in them, who has not often felt astonished at the number of plants and flowers such people can crowd into a small space, often working at short and irregular periods, and with poor tools? I once saw an old woman digging hard in her garden with a table knife, and when I suggested the absurdity of using wrong tools for wrong work, received the indignant reply, "It's all very well to find fault, but I dig with the best spade I've got—not a very poor one either, and my plants come up and flower just as well as if I worked with a bran new steel spade. Across the way there, they are waiting doing up their garden until they can buy a new trowel, the old one was left out all winter to rust, and they are missing the best growing time. It's a good thing to make decent work with bad tools."

Then, too, gardens have a great charm for us all; they are the bit of breathing space we like to call our own, and in which we may do just as we choose—it may be where our vagaries run riot, our peculiar fancies crop out to daylight: still it is our own. We may sow our seeds in tiny dots, just as much as a child's cup could cover, all up and down, without any thought of height of growth, or colour of flower; or we may scatter them broadcast, as the German traveller did his choice Ten-week Stocks, and like him may wonder and wait, and wait and wonder they come not up to daylight. Or we may sow the whole slope of a long terrace with Mignonette, as the poor curate fresh from town did, thinking there could not be too much of what was sweet. Or we may turn all our flower borders into short, soft grass for our little ones to play upon, or for larger children to roll balls about. Still, our garden gives us back full measure of enjoyment. There are times when it does more than this, when its work is at rest. How many weary overtasked heads find balm and strength doing their gardens beneath the budding trees! And many a poor lady, tired of the sound of her solitary needle, seeks change and pleasure in pricking-out her Asters and Phlox Drummondii—doing it, spite of all professors in the art have said to the contrary, in gloved fingers, otherwise she could not do it, for the fresh soil has a strange power of roughening what is smooth, and would thereby render other work impossible.

No country English house seems what it should be without a garden—a place for work, and rest, and enjoyment; and its extent has very little to do with the measure of that enjoyment. Though much may be said in favour of the capabilities of a large one, a small one is not without its advantages. It is more under the command of its owner; is nearer to the home; often furnishes more variety, for it is less under the influence of fashion; its owner dares to cultivate long-discarded plants and flowers, and to venture, without any fear of failure, into new untried ways—ways strange and hazardous, which a veteran gardener who had solved all the mysteries and climbed all the heights of knowledge would never think of going, seeing the probable end. Yet even the risk is a pleasure, and the blame can fall but on one, the master workman.

Then, too, small gardens are more lived-in than large ones. They are resorted to at all hours of the day, from early morning until sunset. Every little plant and flower and coming bud is watched, and noted, and wondered about, and loved. The garden is as it were a summer home. And if it has a thick hedge to afford shelter from the wind, so that the leaves of

our book turn not over before their time, and the repose of our work-basket be not disturbed, a tree to shade all from the sun's heat—then to many possessors of small gardens is happiness complete.—*MAUD.*

HEDGE PLANTS.

(Concluded from page 237.)

BLACKTHORN.—Formidable as this plant is as a solitary bush, or when it forms a portion of a hedge composed of miscellaneous shrubs or bushes, it is seldom we see it employed by itself to form a hedge. It does not bear cutting so well as the Whitethorn, neither does it grow so fast, at the same time it is, perhaps, less liable to injury than any class of hedge plant we possess. It suffers less than the Whitethorn from the attacks of rabbits; and to those who admire early-flowering shrubs, it is amongst the first of our native ones that blossom, and its flowers are also of much beauty. The Blackthorn thrives best on a rather stiff soil, but it is not very particular as to situation; its growth, however, is not fast, and it seems to produce suckers in greater abundance than neatly-trimmed hedge plants should do. Where there is a difficulty in rearing the Whitethorn, this plant may be substituted for it with advantage.

WHITETHORN.—This is unquestionably the most popular and useful hedge plant we possess, and the general aspect of our country would be poor indeed were this plant no longer cultivated. It is not, perhaps, any exaggeration to say that no individual tree or shrub is propagated and planted to an equal extent with this, and well it repays the attention given it. So generally is it used as a hedge plant, that when the term hedge is used we conclude that one of the Quickset is meant, other hedges receiving a special designation. It has its favourite positions, and one of the best is a dry stony soil, porous and accessible to its roots for at least 2 or 3 feet; in such a position its progress is rapid, and it is also more tenacious of life than when in a soil of an opposite character. A dry hungry gravel is not the place for it, a sound loam being better; but very good hedges are often met with in those dry warm soils which produce good Barley and Potatoes. The Whitethorn hedges in some parts of Bedfordshire are good, and so are those in most districts favourable to agriculture.

The modes of managing Quickset hedges differ widely in different districts; in many parts of England it is common to plant the hedge on the side or top of a bank, with a ditch in front, and in some bleak neighbourhoods it is allowed to grow and branch out as much as it likes, with a regular cutting-down once in ten or twelve years, the materials thus obtained being used to make what are called dead fences, or to repair others. The bushy irregular growth a hedge of this class presents is certainly more pleasing to the eye than the closely-shaven line met with in other places, but it occupies more space; its utility, however, is in the shelter it gives to stock, and the little trouble it involves. The number of hedges of this class, however, decreases every year, and close trimming seems to be the order of the day. The most common plan, where the situation is favourable, is to plant on the level ground, and dig a ditch on the most exposed side; trimming for the first two years, however, ought to be limited to the winter, after that it may be done in the summer, or when the plant has become well established. The most common shape is not by any means that most to be admired, or rather the shape or section is altered by degrees until it becomes objectionable. Assuming the top to be pointed ridge-fashion, the greatest width very often is about 1½ foot from the top or thereabouts, and there is very little growth at the bottom. To remedy this, or rather to devise another mode of making the Quickset hedge more formidable to cattle, the farmers in Cheshire cut their hedges so that the section would resemble an equilateral triangle, the bottom being about 4 feet wide, and tapering from thence to the top. Some may say that the merits of this plan are more than counterbalanced by the greater extent of ground the hedges occupy, and this would certainly be urged against them in places; it may, nevertheless, be the one most likely to secure a good long-lived hedge, and when such a hedge is really good it is difficult of approach by cattle or anything else, as the width at bottom renders it difficult to climb over. Nevertheless, I certainly prefer the mode in which Quickset hedges are treated in this part of Kent, for they have the advantage of occupying very little ground, and when well managed are pretty and useful.

The plan differs in no respect from that adopted elsewhere,

excepting in the narrow trimming the hedge receives when full grown; but on being planted the young plants are not cut down the first year, but are allowed to become established one year, when they are cut down. If the ground is well attended to and other things are favourable, a strong vigorous shoot may be expected, and no trimming ought to take place until the end of the season's growth, when the side shoots are cut in rather closely, and a little of the tips taken off. This is repeated the second year, but after that the hedge will bear and require cutting a little in the middle of summer, but this is certainly not advisable until the plant has attained some size and strength, for cutting in any deciduous plant during the period of its growth certainly checks that growth. In the early period of a hedge's growth this is not advisable; afterwards it may be done with advantage. The trimming or clipping, I may observe, is done with the view of keeping the hedge as narrow as possible, consistent with strength and the requirements of a hedge, and I believe there are fences in my neighbourhood that are, when closely trimmed, not a foot thick in any part, and yet have been kept so for twenty years or more, and so close all the way up, that it has been the boast of the farmers that some of their fields would keep in a hare everywhere but at the gate. After several years' cutting, the hard closely-trimmed hedge has a woody appearance, and is exceedingly strong if it is growing on a soil favourable to the Whitethorn. The dry stony soils of some districts are more favourable to it than those of a contrary description, and on some waste lands of this kind that were enclosed forty or fifty years ago by Quicksets planted in straight lines generally intersecting at right angles, we may find some of the best specimens of Quickset fence in the kingdom. In the district alluded to it is common to plant the Quickset on the level ground, and if it be a meadow, a space of about a foot or so on each side of the collar of the plant is kept clear and free from weeds. If the ground is arable, cultivation is carried on to the roots of the plants without any loss or waste, as is sometimes the case where there is a ditch or bank. Cleaning out the weeds from the base of a hedge in a meadow, as is sometimes done, certainly gives it a neat appearance.

BEECH.—This is generally planted rather for shelter than as a fence, and frequent trimming tends to cause it to keep its old leaves on all the winter. The Beech also grows to a larger size than most other hedge plants, and does not look badly in the summer. The Hornbeam is sometimes substituted for the Beech, both being alike in their growth and property of retaining their old leaves during the winter. As objects for shelter they are certainly desirable, but beyond that their merits as hedge plants would appear to be inferior to those of many others.

Miscellaneous plants or trees occasionally used are so various that it is scarcely possible to enumerate them. Generally speaking, in old hedges by the side of woods we find everything that grows near them, and possibly considerable portions of many such fences were naturally produced, and filled up a little afterwards by the cultivator. In such we often meet with Briars, Brambles, scrubby patches of Oak, Hazel, Maple, Poplar, and other kinds of deciduous trees; but these are mere makeshifts, and not to be recommended, except in special cases. In one case I saw an Elm hedge, upwards of 30 feet in height, partly entangled with Ivy, and trimmed tolerably accurately; being for shelter it served its purpose well—certainly much better than a row of Spruce Firs would have done, as this tree is rarely met with in a healthy condition on its exposed side, whereas a deciduous tree generally stands better against the elements. Ornamental hedges of other kinds may also be met with, some being composed of such shrubs or trees as the fancy of the grower may suggest, and more kinds of fruit trees than one are used in this way. I may add, as regards the choice of a hedge plant, that certain soils and situations favour the growth of certain plants, and the requirements of the case have also to be consulted; but amongst the plants I have named, one or other will be found to meet the wants of most places.—*J. ROBINSON.*

ORNAMENTAL AND FLOWERING SHRUBS.

(Continued from page 240.)

PALURUS ACULEATUS.—Flowers yellow, small, June to August. Leaves small and shining; shoots very spiny. The flowers are succeeded by a curious fruit, said to resemble a straw hat. 8 to 12 feet. Cuttings of the roots, or seeds in heat.

PHILADELPHUS CORONARI.—(Mock Orange).—Flowers white, with a

sweet, powerful odour. The double variety is very handsome, and the variegated form desirable. 8 to 10 feet. Layers and cuttings.

PHILADELPHUS LAXUS GRANDIFLORUS.—Flowers white, large, produced in profusion in June. A remarkably fine shrub. 8 to 10 feet. Layers and cuttings.

PHILADELPHUS GORDONIANUS.—Flowers white, numerous, large and very fine, in July. 8 feet. Cuttings and layers.

POTENTILLA FRUTICOSA.—Flowers yellow, in July and August. Cuttings and seeds. 3 feet.

PYRUS ARBUTIFOLIA.—Flowers white, in May, succeeded by dark red fruit. 4 to 6 feet. Suckers.

RIBES AUREUM.—Flowers yellow, sweet, in April and May; very desirable. The varieties *Gordonianum* and *flavum* are good. 6 feet. Cuttings and layers.

RIBES SPECIOSUM.—Flowers deep red, pendulous, in May; very fine. 6 feet. Cuttings and layers.

RIBES SANGUINEUM.—Flowers red or rose, drooping, very profusely produced, and very handsome, in March and April. The variety albam with white flowers is very fine, and glutinosum and atro-rubrum are very desirable. The Ribes are among the handsomest of spring-flowering shrubs, and should be extensively planted. They make fine standards, and are very effective in flower gardens when on clean straight stems. 6 to 8 feet in good soil. Cuttings and layers.

RHUS COTINUS.—Flowers green, in panicles, very elegant, in June and July. 6 to 8 feet. Layers.

RHUS GLABRA.—Flowers elegant, in panicles, succeeded by red fruit; very desirable. 12 feet. Layers.

RHUS LACINATUS.—Flowers rose, leaves deeply cut, and very fine. 5 feet. Layers.

RUBUS FRUTICOSUS (Bramble).—The double rose and double white varieties are very fine, and grow almost everywhere. Layers.

ROBINIA HISPIDA.—Flowers rose, large and produced in profusion; leaves Acacia-like, rendering it one of the most ornamental of shrubs. It flowers from May to September. Grafted on the Thorn Acacia standard high it is very effective, but does not succeed except in mild sheltered situations. 8 feet. Seeds.

SPIRÆAS arifolia, *Lindleyana*, *hypericifolia*, *opulifolia*, *prunifolia plena*, *grandiflora*, *salicifolia*, and *ulmifolia*, all with white flowers; and *S. callosa*, *Douglasii*, and *bella* with rose flowers, are amongst the handsomest of flowering shrubs, and, deserving of every care, ought to be extensively planted. 6 feet. Cuttings, layers, and suckers. They succeed tolerably well in the shade of trees.

STAPHYLEA TRIFOLIATA.—Flowers white, pendulous, and handsome, in May and June. 8 feet. Cuttings and suckers.

SYMPHORICARPUS RACEMOSUS (Snowberry).—Flowers rose-coloured, small, in summer, succeeded by large white berries. Has no equal for growing in the shade of large trees; in fact, it will grow almost everywhere, and on that account is very desirable. 6 feet. Suckers.

SYRINGA VULGARIS (Lilac).—Well known, and very suitable for general shrubberies. There are several varieties, all ornamental and producing a profusion of fragrant flowers varying in colour, being lilac, white, purple, reddish, and bluish. They flower in May. 10 feet. Suckers and layers.

SYRINGA PERSICA.—Flowers pale purple, sweet, in dense clusters, very fine, in May. The white variety and that with cut leaves are fine. 6 to 8 feet in good soil. Suckers and layers.

SYRINGA ROTHOMAGENSIS SAUGANA, probably a variety of *S. persica*, having deeper-coloured flowers and more compact bunches of flowers. It is also a stronger grower. 8 to 10 feet. Suckers and layers.

SYRINGA JOSSILEA.—Flowers dark lilac, very fine. 6 to 8 feet.

SYRINGA EMODI.—Flowers white, numerous, and good. 8 feet.

VIBURNUM OPULIS (Gueldres Rose).—Flowers white, in large corymbs, in May and June. Succeeds well in damp ground under trees, and is very ornamental everywhere. There is a dwarf variety, fine for shrubberies. 8 to 12 feet. Cuttings, seeds, and layers.

VIBURNUM LANTANA.—Flowers white, in June, succeeded by red berries changing to black. The leaves assume a rich red tint in autumn. 12 feet. Seeds and layers.

VIBURNUM LENTAGO.—Flowers white, in July, succeeded by black berries. It is a desirable sort. 8 to 10 feet. Seeds and layers.

WEIGELA ROSEA.—Flowers rose and white, sweet-scented, produced in clusters in April or May. It is one of the very best shrubs of low growth, thriving in any open situation, and in almost all soils. As a plant for forcing it is excellent. *Stelzneri*, *nana* variegata, and *Treloii* are pretty and superior varieties. 4 to 5 feet. Cuttings.

WEIGELA AMABILIS.—Flowers deep rose, in early summer, very fine. There is a pretty white variety, as well as several others.—G. ABBEY.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

ARISTOLOCHIA RINGENS (Gaping-flowered Aristolochia). *Nat. ord.*, Aristolochia. *Lim.*, Gynandria Hexandria. Twiner.—Native of Santa Cruz, in New Grenada. Roots, called "Guaco" by the natives, esteemed an antidote for snake bites. Flowers green, marbled with purple; open in September.—(*Bot. Mag.*, t. 5700.)

IPSEA SPECIOSA (Beautiful Ipsen). *Nat. ord.*, Orchidaceæ.

Lim., Gynandria Monandria.—Native of Ceylon. Its flowers are yellow, and open in January.—(*Ibid.*, t. 5701.)

HIBISCUS MARMORATUS (Marbled-flowered Hibiscus). *Nat. ord.*, Malvaceæ. *Lim.*, Monadelphia Polyandria.—Native of Mexico. Flowers white, marbled with rose. It bloomed in a stove at Kew in February.—(*Ibid.*, t. 5702.)

DENDROBIUM CUMULATUM (Clustered-flowered Dendrobe). *Nat. ord.*, Orchidaceæ. *Lim.*, Gynandria Monandria.—Native of Moulmein. Flowers white, tinged with purple, and vanilla-scented. Bloomed in September.—(*Ibid.*, t. 5703.)

RAPHISTEMMA CILIATUM (Ciliated Raphistemma). *Nat. ord.*, Aselepiadaceæ. *Lim.*, Gynandria Pentandria.—A climber from Penang; corolla ciliated. Flowers in October.—(*Ibid.*, t. 5704.)

GESNERA EXONIENSIS.—Raised by Messrs. Lacombe, Pince, and Co., Exeter, by crossing *Gesnera fulgens* and *G. zebrina*. Flowers orange scarlet.—(*Floral Mag.*, pl. 381.)

CROTON MAXIMUM.—Brought by Mr. J. G. Veitch from the South Sea Islands. Leaves about a foot long and 3 inches wide, golden, with bands of green radiating from the midrib. (*Ibid.*, pl. 382.)

AMARYLLIS, *Prince Teck*.—Seedling raised by Messrs. Veitch. Colour creamy green, marbled at the edges with crimson.—(*Ibid.*, pl. 383.)

ONCIDIUM CALANTHUM.—Obtained by Messrs. Backhouse and Son, York, from the high Cordilleras of Ecuador. Flowers yellow.—(*Ibid.*, pl. 384.)

DIPLODENIA AMENA.—"This, which we may at once state is a most valuable acquisition amongst stove plants, has been raised by Mr. Henry Take, gardener to R. Nicholls, Esq., Bramley, near Leeds. Mr. Take also raised from seed the lovely *Dipladenia amabilis*, which was sent out in 1865 by the Messrs. Backhouse & Son, of York. This latter was the result of a cross between *D. splendens* and *D. crassinoda*, the former being the male parent, and the seed was sown in March, 1862. This *D. amabilis* is a great advance upon *D. crassinoda*, having a more robust habit, and being of a more brilliant colour, and a freer bloomer.

"Mr. Take is so successful a grower of *Dipladenias*, that we cannot do better than give a short account of his method of growing them. The soil he uses is composed of rough fibrous peat broken to the size of walnuts, with a liberal mixture of sand, adding a few rough bones and good drainage, and potting firm. In the winter the plants are taken off the wires or trellis, and are kept dry in a house of medium temperature. If they are wanted for a June exhibition, the plants are started into growth in November or December at the latest. If for August exhibitions, the plants are started in February. Mr. Take does not plunge the plants, finding, especially in winter, that they do better without. *Dipladenias* do best by keeping them moderately dry until in good foliage. Many of these plants are killed by over-watering. A moist atmosphere of 65° to 70° is best for early growth, gradually increasing to 80° and 85° as the plants progress. They also do best when grown near the glass and well exposed to the light."—(*Florist and Pomologist*, 3 s., i. 73.)

NOTES AND GLEANINGS.

THE Duke of Devonshire's gardener at Chatsworth, Mr. Taplin, having given up his charge, we understand to take the management of an extensive nursery business at New York, he is succeeded by Mr. THOMAS SPEED, gardener to Sir E. S. Walker, Bart., at Berry Hill, near Mansfield. Mr. Speed and his brother, when at Edmonton, were most successful exhibitors of stove and greenhouse plants, and since he has been at Berry Hill he has taken a high position as a fruit-grower, and gained many prizes at the London exhibitions. Last September we had the pleasure of ourselves inspecting the gardens at that place, and were much gratified by the careful and excellent manner in which they were managed, and particularly with the admirable crops of Grapes, Pine Apples, and Figs. The Muscat house, 50 feet in length by 19 in width, was a beautiful sight, the roof being covered with large heavy bunches, and in a late vinery of similar length were bunches of Gros Guillaume from 15 to 18 inches long, of Muscats from 12 to 14 inches, and not long, but broad as well. Lady Downe's and Trebbiano were also in splendid condition. In the wider sphere of action which Chatsworth affords we may confidently expect that Mr. Speed's skill and steady perseverance will achieve still greater results.

— MESSRS. LANE & SON, of Berkhamstead, are now hold-

ing in the Eastern Conservatory Arcade, in the gardens of the Royal Horticultural Society at South Kensington, an interesting display of Spring-flowering plants. It opened on the 9th inst. and will continue till the 18th, when the Society's second Spring Show will be held. Roses, of which the Messrs. Lane have been such frequent and successful exhibitors, form the centre of attraction; other groups, consisting of Azaleas, Rhododendrons, and miscellaneous plants, including fruiting Aucubas, combine to make a gay and excellent exhibition.

— We have to remind our readers that the sale of the beautiful new HYBRID VARIETIES OF COLEUS, raised by Mr. Bause in the Royal Horticultural Society's Chiswick Garden, is appointed to take place at Mr. Stevens's Rooms, King Street, Covent Garden, on Wednesday, April 22nd. The varieties, twelve in number, are decidedly a great advance on any of the forms of Coleus which have hitherto appeared, both as regards size of foliage and richness of colouring, and doubtless the competition for their possession will be very keen.

WORK FOR THE WEEK.

KITCHEN GARDEN.

WHILE young crops are advancing in all parts of the kitchen garden, the ground about them can hardly be stirred too often, to keep an open, pulverised surface, and to destroy weeds with the first warm rains. The young crops after this time will advance rapidly, and unless such as require it are thinned out in time, they will soon be injured. *Broccoli*, sow late spring sorts on a light border, and make a second small sowing about ten days later; at planting time you will have a choice of two sowings. *Beet* may be sown towards the end of the week. *Cauliflowers* may have the glasses removed from them altogether, and see that they do not suffer from want of water. *Kidney Beans*, a few of these may now be planted on a warm border for a first crop, but if they are sown in boxes about the second week in May, and transplanted when all danger of frost is over, they will come in sooner than those planted now in the open ground. *Successional crops* of Peas, Beans, Spinach, Radishes, and other salads, should now be sown oftener, as they will come more rapidly into use through the summer. *Salsify* and *Scorzonera*, sowing may be deferred for another week; if sown too early they are apt to run to seed. Continue to harden off Tobacco plants, Capsicums, Tomatoes, Basil, &c., which should now be strong enough to stand in a close cold frame, to be shut up early in the afternoon for a week or two, after which they should have air night and day till they are fit for planting out. Seeds of any sweet or pot herbs, if not already sown, should be put in forthwith.

FRUIT GARDEN.

If the present dry weather continue it will be advisable to water trees against walls having steep sloping borders, as if the roots become too dry the blossoms will not set well. Previously to watering, fork over the border, repeating the operation at short intervals and in warm days, until it becomes necessary either to mulch the border, or, in cold, late situations, to cover part of it next the wall with tiles for the purpose of causing more heat to be radiated against the trees, so as to forward the ripening of the fruit and young wood. Proceed with disbudding Peach trees, &c., never losing sight of the fact that it is from your summer management, and not from any treatment you can give in winter or spring, that you can insure healthy, fruitful trees. Killing wasps should be persevered in from this time till the end of May. Every wasp now killed is as good as a nest destroyed next August. From the mildness of the winter, if the summer be dry, we may expect them this year in increased numbers.

FLOWER GARDEN.

The weather is now so inviting that it requires a strong resolution to resist the temptation to begin planting out the half-hardy plants in the flower garden. It is well, however, to be very cautious, as there is nothing gained by planting out before the middle of May, while there is every probability that between now and that time we may have some very severe frosts. I have known persons tempted by the fine weather in April to turn out *Calceolarias* and bedding *Pelargoniums*, and the consequence was that several dozens of the plants were killed, while those which survived were very materially injured, and did not bloom till late in the season. Late-laid turf and late-planted trees and shrubs will require constant attention in being watered so long as the weather is dry. If any of the

flowers require a change of soil, let it be done without delay. Complete any extra work in any part of the grounds in order that the men may proceed with the regular garden work. Great care and attention must now be directed towards the Auricula, in order that the trusses may not be drawn up weakly. They should be able to stand erect without support. Continue to thin out all misshapen pips. Polyanthus in exposed dry situations have suffered during the past hot weather. They require but little sun, and that early in the morning. Ranunculuses are fast coming up. Riddle some leaf soil or very rotten cow manure over the beds, and as the plants come fairly above ground press the soil on a dry day closely round the neck of each. Pansies are now making rapid growth, and as they are often exhibited at spring shows, they ought to be carefully shaded and attended to. The florist will visit his beds with candle and lantern in order to detect slugs, earwigs, &c.

GREENHOUSE AND CONSERVATORY.

This is a good time to cut back duplicate chambers so as to have them in flower in succession. Where new conservatories have been lately planted, or old ones re-arranged, the principal object should be to induce the plants to make a vigorous growth early in the season, and to take a strong hold of the new soil; afterwards there will be plenty of time to ripen them off long before winter. For this end you ought to keep the house more like a stove from this time, only giving air from 11 A.M. to 3 P.M. Syringe heavily in the afternoon with rain water if possible, and after thus chilling the house you may give a little air till dusk if the day has been hot, and you may expect the thermometer to be about 50° in the morning. As very little syringing can be done in conservatories in general on account of the flowers, and as flowers do not last so long in a dry atmosphere, some degree of moisture must be kept up by pouring water on the paths or under the stages. Blinds are now indispensable in the middle of the day. After the middle or end of April gardeners begin to change the spring treatment of their greenhouse plants. Hitherto every means has been taken to keep back early growths, and now that all the plants are in active growth and the season so far advanced that any necessary amount of air and moisture can be given in hot weather, the plants may be more encouraged to make a rapid growth, especially young plants. When the evenings are cold the house should be shut up closely, and air should not be given in the morning until the sun heat warms it considerably.

STOVE.

The general potting is now about finished, and many of the first-potted plants have made a considerable growth. Climbers and specimen plants also have received the direction and shapes they are intended to fill up this season. Propagation and seed-sowing are now nearly over in this department, and all the bulbs and other plants at rest during the winter are now in growth, so that only the common routine of watering, giving air, famigating, or otherwise cleaning plants, and training them, will be necessary for some time. Be very sparing of the fire, and keep the atmosphere very moist in fine sunny weather.

FORCING PIT.

Where Cockcombs, Balsams, and other tender annuals are used, this is a good place to bring them forward through their early stages. *Neriums* ought now to have gentle forcing. Camellias to flower early should also be forced to form their buds, as well as the more choice Azaleas which have done flowering. A few plants of *Crassula coccinea* now put into heat will flower some weeks earlier. In short, where there is a good conservatory to be kept gay all the year round, and plenty of plants for the purpose, the forcing pits need never be at rest, and may always be usefully employed.

PITS AND FRAMES.

Many of the annuals which were potted-off early may now be planted out. Where a large stock of dwarf *Chrysanthemums* is required for flower-garden purposes in the autumn, the old stools or plants must be planted out in rich soil at about 4 feet apart, so as to leave room for their being layered in August. Old plants planted now at the foot of a wall in very rich soil will cover a wall 6 or 8 feet high by the autumn, and if properly trained will flower splendidly. Increase, pot-off, and harden your stock of flower-garden plants as fast as possible. Most of these plants are quickly inured to stand out in sheltered places, or under hoops covered over with mats, and the longer they are here the finer they will look after being planted out in the flower garden.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Cauliflowers.—Went over all our earliest Cauliflowers that were and partly are assisted with hand-lights, taking out some of the plants and planting them in a trench, and mulching and earthing-up those left, and then placing the glasses on the raised earth without any other support. But for the sharp frosty mornings (the leaves of the Cauliflower plants being hard on the 10th and 11th), we would have dispensed with the glasses, as the plants by bending out would have received more room. If the cold nights continue we may give a slight covering of litter. Cauliflowers may thus be had very early where they are required to come in before the Broccoli is nearly over; but the latter, however good, loses its attractions after the more delicate Cauliflower is to be had. We frequently adopt a plan here with early Cauliflowers, which may be useful to those who have a stiff soil and little room. A raised bank, sloping to the south and 5 feet in width, just affords room for two hand-lights in the width with a space between them. Lengthwise along the border the hand-lights are placed in these two rows, about 30 inches being left between the first two lights and the next two, and so on. The ground is prepared before the lights are set on the border in the autumn, and generally about nine small plants are pricked-out under each light. These are finally thinned-out to about five in the spring, say in the end of March. All this is in the usual way. The little peculiarity is, that in earthing-up and elevating the glasses as stated above, we dig out a rather deep trench, one spit wide, in the centre of the 30-inch openings. This enables us to give water more freely in stiff soil when we want to swell the heads rapidly. Such a trench left exposed might, in loose soils, be apt to render the Cauliflower too dry; but we prevent that after the above earthing-up by covering the ground and the sides of the trenches with litter, short grass, &c. The sun therefore chiefly acts on the soil where the plants are growing, and if the littered ground absorbs little heat, neither does it part with it, nor with the moisture so necessary for the Cauliflower. With plenty of room we might dispense with the trench, but in many seasons it affords advantages of its own. By moving the litter to the level surface, and placing rotten dung in the trench, we often have early Cauliflower and early Celery on the same narrow border, the trench doing for earthing-up the Cauliflowers, whilst the banks on which the Cauliflowers stood come in for earthing-up the Celery, and the Cauliflowers give shade to the Celery when it needs it at first.

Peas and Beans.—Sowed successions, and staked up the former, it being always of importance to do that work in dry weather, and when the ground is dry.

Sowed more Carrots and the main crop of Beet, just moistening the seeds, also Turnip seed, and sprinkling and working-in with them a little red lead so as to cover them. This will keep birds from them until above ground. We are doubtful then, especially in the case of the Beet, as though the red colour of the lead seems to frighten the birds, the reddish colour of the young leaves is an irresistible temptation to them here, so that for years we have been forced to raise and transplant. If we can get the Beet well up we shall use a net as soon as it peeps above ground, and thus, if possible, avoid the labour of transplanting. Rolled the ground in which Onions, Carrots, and Parsnips were sown. A warm rain now would do much good. The nights have been sufficiently severe to compel us to turn some leaves and place a little rough hay over the heads of Broccoli, and even Potatoes close to walls needed a little protection.

Sea-kale.—Planted on a good piece, and must get another piece ready. Plenty of Sea-kale to go to makes the gardener feel more independent in winter. What trouble we used to have in our young days with huge mounds of dung over Sea-kale, and then turning these mounds without obtaining a dish, and yet some of it as long as one's arm, and so watery as to be fit for nothing! This vegetable, even when strongest, should rarely exceed 7 inches in length. An "ADMIRER" has lately expostulated with us, that if we recommend taking up for winter we might give some advice to those who have no place to take it to, and must have it where it grows. Well, we will show our anxiety to oblige by telling what is the easiest and safest way of securing a supply of this vegetable out of doors in winter. We have lately described how best to obtain it in spring. The best plan of dispensing with the fermenting mounds is to clear away the leaves of the Kale as soon as they decay in the autumn, and cover the ground with litter before

the ground loses the summer heat. By this means, with something like a foot of covering of leaves and litter, fine gatherings may be had from December, and there is no danger of overheating. Pots or boxes will enable you to have it cleaner; but with 10 or 12 inches of leaves and a little sprinkling of litter on the top to prevent the leaves blowing about, we have had fine gatherings, the Kale coming white and sweet out of the leaves alone. For economy of material, however, there is no comparison between this mode and taking up and placing in leaf mould over a hotbed, say from 18 to 24 inches high. A bed 6 feet by 4, and covered with an old box or packing case, will yield a large number of dishes. One of the simplest modes is the following:—Make a dung bed 7 or 8 feet wide, and as much in length, and 15 inches deep. All round the bed build up on it a wall of dung 15 inches high and 18 inches wide; place the plants thickly in the bed; put wattled hurdles across the dung walls, and cover them with litter. Move a hurdle as you wish to gather.

See last week as to watering and using water warmed to all things, especially under glass.

Heated Water.—Lately we alluded to heated workshops in gardens. One essential which we have never had, but which were we in business we would make a certainty, would be a supply of heated water, without being forced to go and borrow what was wanted from the cisterns and pipes in heated houses. The simplest way for securing heated water would be to have a boiler like a wash-house boiler for the purpose. Another good plan would be to have a large cistern out of doors self-supplied, with coils or stacks of piping in the bottom connected with a heating apparatus. With plenty of heated water judiciously used we are convinced that we could almost bid defiance to insects and other evils. Even when we take water from a heating apparatus, that water is anything but suitable for many tender plants, whilst by either of the modes referred to we could have the heated water as pure and wholesome as the cold. Such heated cisterns, or boilers for heating water, may be more general than we suspect; all we can say is, that we know of few places where there is such a convenience accessible to all departments, and to which a man can go and supply himself without entering a house of which another man has the charge. There is endless trouble and mishap when anybody can draw water from a tap or cistern attached to a hot-water apparatus in a house; and often the man who takes the water is tempted to forget to replace it with cold, and evil results are apt to ensue. In a cistern out of doors, covered with wood as a non-conductor, and heated by pipes, the water would always be clean and pure.

Orchard Houses.—In the first the fruit against the back wall has set very thickly and is now swelling, and we are disbudding, or rather shoot-thinning, gradually. The trees in pots in the border of this lean-to house are now also set, but not nearly so forward as those on the back wall. We refrained until lately from sprinkling these trees in the border; but in very hot dry days we sprinkled the earth floor or border with the syringe, that the vapour thus gently raised might prevent the blooms getting too dry. As a flower show, these pot trees have been pictures of beauty. The trees against the back wall have been gently sprinkled in the afternoon before shutting up the house. This shutting-up has varied with the weather. In this bright weather we shut up rather closely about half-past three, not minding if the thermometer with sun heat should rise to 80°, or two or three degrees more, as it will fall gradually. Here, too, after giving a little air at the top early, we increase the ventilation by degrees, as we shall want this house to succeed the Peach house forced in the usual way. In the later house we give air early, and by breakfast time very liberally, and in fine mild evenings do not shut up until late, and that chiefly for security. We have a few Cherries in the first house, and to do them justice, though we shut the house earlier, we leave a little air opposite them all night. If we want to have Cherries early in pots, we find it best to let the pots stand in the cooler more airy house until the fruit is set, and then move them into the other to swell more quickly in the higher temperature procured by giving less air and shutting up earlier. The shutting-up of these houses with large squares and open laps is different from shutting-up closely, where there are no laps or close laps. In the latter case, unless in frosty or very stormy weather, we would leave a little air on constantly; for a very little, even such as that which comes through open laps, will prevent anything like a stagnant atmosphere.

We thus treat the two houses differently, because it would only be waste to have bushels or barrowloads of Peaches

ripening at the same time. These orchard houses were made by merely glass-fronting an old wall, and without saying a word against span-roofed houses, there is an advantage in having a back wall in cold places, and where no artificial heat is given; and even in these lean-to's fine crops can be obtained, early vegetables forwarded, and winter ones protected. If such work were done as a commencement, we should concentrate early kinds in the first house, and late kinds in the late one, to prolong the season of fruit-gathering. Even for amateurs with only one house, and that not a large one, we would have a division in it, and then by the selection of kinds, and the keeping one division much more open and airy than the other, there would be a great difference in the ripening.

Questions come to us almost every week, "Can you recommend the pot system of culture?" As a matter of economy in labour, &c., we say, No; as a matter of pleasure and giving much variety of produce in little room, we say Undoubtedly, yes, after having had a fair experience with all kinds of fruit trees except Apricots, with which we have as yet done little, but which we have no doubt would do equally well with others when tried, but before doing much with them we would study the doings of our veteran instructor Mr. Rivers. To all amateurs who feel a pleasure in attending to their fruit trees or houses the pot system is invaluable, enabling them to have much variety in little room, just as the cordon and small pyramid, or small bush system of fruit-growing will enable the holders of small gardens to have a great variety of fruit out of doors.

Our chief objections to pot trees arise from the great amount of watering required, and to lessen this we plunge the pots three-quarters of their depth in the ground, and we have just surfaced the soil in the pots in one house with a couple of inches of old mushroom dung, and a little soot in it, and will repeat the process as that disappears. This not only helps to enrich the soil, but renders such frequent waterings unnecessary. Last season we put a rim of thin turf round the sides of the pots. The plants have not been potted for a number of years. Amateurs who like neatness, might have strips of zinc from 2½ to 3 inches deep, which they might fix inside the rims of the pots before applying the mulching. This mulching, it will be thus understood, is considerably above the level of the rim of the pot, but that with ordinary care does not interfere with proper watering. Some recommend fresh dung, as fresh horse droppings, for the purpose, but with those who are unpractised this may be easily overdone; and if not well heated previously there is a likelihood of a good many seedling oats appearing, all of which must be pulled out; and as a general rule gardeners have enough to do without making work in the weeding of pot trees. We forget how often we mulched our trees last year. The mulching soon disappears, but its effects are seen.

In the cooler house the Peaches, &c., have just set thickly and healthily against the back wall. In pots in front, Plums are setting; Apricots set and beginning to swell; Peaches beginning to set, and Cherry trees only too much of a mass of bloom, and noisy with the hum of numberless bees, which have taken the dispersing of the pollen dust entirely under their care, and saved us all trouble in this direction. This house contains plenty of Strawberry plants in pots, &c., which except at the front will have to be moved before they come into bloom, as they would be too shaded to set freely on the ground. The watering of these and other things has kept enough of moist vapour in the atmosphere of the house without resorting to syringing; but in another week or so we will lash the back wall, and the fruit trees when it can be done with safety.

In the first or closest-kept house Vines are just swelling their buds, showing that they will come out in shoots ere long. In the late vinery, filled with bedding and other plants, and kept as cool as possible, with air on at night until the late frosts, the young shoots are about 2 inches long; and though we will keep them cool for some time longer, these shoots must have no check, as that would injure the young branches. All the roots are in an outside border unfortunately, slightly protected in winter with litter, but unprotected for some time past.

We slightly fumigated the Peach house for the first time, as a few whitish green fly appeared on some rows of Strawberries, and besides injuring them might have gone farther if let alone. The garden engine played on the glass roof to keep the smoke in, and thus a less quantity of tobacco paper does than when such a precaution is not adopted. When smoking is resorted to as soon as a few insects appear they are easily destroyed when young—a matter that should never be forgotten, as the older

the insects the more difficult they are to kill, and instead of one you may have many generations of them to battle with if you procrastinate.

ORNAMENTAL DEPARTMENT.

Mowed the lawn where most conspicuous after giving it a good rolling. Lately the grass has been too crisped in the morning for mowing, as the ice would gather on the sedge, and besides, cutting under such circumstances is very apt to blacken and injure the lawn. There has been little growth for the last ten days, the cold of the night counteracting the sun heat of the day.

Proceeded with putting out under temporary protection bedding plants, and pricking-out seedlings. We have been obliged to use a little straw and laurel boughs over cloth, mats, &c., on flat earth pits, as the lower and flatter they are, and the nearer the plants are to the protecting medium, the more liable are they to be injured. The dry days have obliged us in some cases either to syringe or to water such plants at mid-day that their foliage might become perfectly dry before night. We would have avoided this, and did in all cases where the plants would hold their own, as, merely on the question of warmth, we prefer the soil to be rather dry about the plants instead of wet, and hence the watering at the roots at planting them out; and somewhat dry soil on the surface is much preferred for all such purposes to watering over the surface. Such drying days, however, rendered syringing or watering necessary in some cases against our will. The weather has been too cold to move the covering, unless for the above purpose, and then only for a short time. Plants under calico wanted no such watering and received none, and most likely will need none for a couple of weeks, after which time we will expose them partly in fine days, the better to harden them off for the open air. Of course for all such purposes water at 70° or warmer, applied in the middle of the day, is better than cold water from a tank or well, and hence the importance of being able to get warmed water as already alluded to.

Sowed the most of our half-hardy annuals—as Zinnias, Stocks, Asters, &c., in pots, and placed them under glass on a slight hotbed. Made up a rough hotbed that will yield a little heat, on which we will sow more, and even some hardy annuals, to be protected for a time, and then raised singly or in patches when well hardened-off. The most of the Asters when well up and hardened will be pricked off in an earth pit, where they can be protected with boughs, and other means for a time. It is always better to sow late, so that the plants may have justice and receive few checks, instead of sowing early, and then letting them be starved and dwindled before planting out. Even as respects hardy annuals, unless sown in the autumn and just established, but low in growth before winter, little is gained by sowing the hardiest out of doors before the end of March. Many seedlings that are hardy when a few inches above the ground, are very tender just after germination has taken place.—K. F.

TRADE CATALOGUES RECEIVED.

George White, 3, Moss Street, Paisley.—*Catalogue of Florists' Flowers, Greenhouse, Herbaceous, and Bedding-out Plants.*

Adam Forsyth, Stoke Newington, London, N.—*Descriptive Catalogue of Chrysanthemums, Dahlias, Tropaeolums, &c.*

T. Sampson, Preston Road, Yeovil, Somerset.—*Catalogue of Bedding Plants and Roses.*

COVENT GARDEN MARKET.—APRIL 15.

TRADE continues dull, and the supplies are in excess of what is required, especially in foreign imports, and clearances cannot be effected at former rates. We may, however, look for some improvement when the holidays are over. The Potato trade is rather heavy, and prices are lower. New Potatoes from Lisbon bring about 6s. to 8s. per doz. lbs.

TO CORRESPONDENTS.

.. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix upon the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

BOOKS (*C. P. Gibson*).—Keane's "In-door Gardening" will suit you. It contains directions for cultivating greenhouse plants throughout the year. You can have it free by post from our office if you order it and enclose twenty postage stamps with your address.

BERRIES (*M. C.*).—They are of the *Aucuba japonica*. If the seeds in them prove fertile, but we think they will not, there must be a male plant in the neighbourhood; or some of the blossoms on your very old plants must have produced stamens. All your specimens are of *A. japonica*.

MEXICAN MAGNIFICA (*G. D.*).—It belongs to the natural order Melastomaceae, and to Decandria Monogynia of the Linnean system. It is a native of Manila. The flowers are pink. It was introduced by Messrs. Veitch, in 1859. A portrait of it is in the "Botanical Magazine," t. 4533.

SORGHUM TATARICUM (*Wye*).—Any seedman could supply seeds; but it is entirely useless to attempt to cultivate it in this country. We are glad you were not swindled as others were.

VINES MILDEWED (*John H.*).—The Vine shoots are infested with mildew. Dust all the infested parts with flowers of sulphur, paint the open places in the wall with sulphur. Give more air even if you require more firing. Taken in time no great harm will be done. It is much more serious when the bunches are affected.

FLOWER-BED PLANTING (*St. Dennis*).—We would arrange your fine-leaved Pelargoniums thus—Mrs. Pollock centre, then Italia Unita, and outside Sunset. To make it more complete we would place a string of *Cerastium* round the outside, and carpet all the rest of the bed with the dwarfier blue *Lobelia*. We would not turn out the Roses in pots in the greenhouse until the middle of May.

WINDOW GARDENING (*C. Hall*).—Ferns, especially in a Fern case, will do well in a north aspect inside a window. Balsams may be potted singly when they are 3 or 4 inches high. You must keep them inside the window until June. Use 3 or 4-inch pots at first, and when filled with roots transfer the plants to 5-inch pots, which are large enough for Balsams in windows. All plants will bloom longer in such an aspect, but they will not grow so sturdy nor knot so well for bloom as if grown where the sun's rays would reach them.

FIG TREES CASTING THEIR FRUIT (*A. S. K.*).—Some kinds of Figs are much given to throw their first crop. The Singleton generally fruits best on the current season's growth. In damp houses there may be something in what you say as to the atmosphere being too damp, but as a general rule, the falling of the fruit is rather owing to dryness at the roots. Fig trees in pots, therefore, ought either to stand on or in the ground, and have a saucer to stand in, the bottom of which should be kept moist. We shall be glad to receive your remarks on Lady Downe's Grape.

CISTERN IN A GREENHOUSE (*A. L. L. W.*).—Circumstances alter cases. You speak of an open cistern in your greenhouse, and that is very different from having a tank all the length of the house and merely covered with boards, with an opening between every two boards. As mildew appeared we think that this open tank was partly the cause, and, therefore, we advised means to be taken to prevent the vapour rising. Of course, in that case, we would draw water by means of a pump, or by an opening large enough to get a pail in, the opening to be covered by a board. We have had open cisterns like yours in a house, and without doing any harm, but we also found harm thus done; and if a cistern is large, a great body of cold rain water passing at once into it very much cools a house. We think, therefore, a wooden cover, partly moveable, would be useful over such a cistern merely as a preventive of evils.

CHANGING THE COLOUR OF PRIMROSES (*Trusty Brandy*).—We have heard that soot, also cow dung, will change the colour, but we do not remember

that turning them upside down was a necessary part of the process. Mr. Abbey informs us that when a boy he planted a number of common Primroses (*Primula acutis*), and they were in full flower at the time. Advised by an old woman he scattered a quantity of soot over and around each in the same manner as is done to prevent the ravages of slugs, and these plants in the following year produced pale reddish lilac flowers. We should be obliged for particulars as to the change of colour, not only of Primroses, but other plants. As we have common Primroses which were planted some years ago, and many of these, or their offspring, now produce reddish flowers of various shades. Very many retain the natural colour of their flowers, but the red-flowering plants are not so vigorous as those retaining their original character.

ORCHARD TREES INFESTED WITH RED SPIDER (*W. M.*).—The specimens sent are severely attacked by red spider; but we do not agree with you as to your not being able to syringe the trees now the blossom is dying off. We would advise your syringing the trees early in the afternoon when there is mild weather and no likelihood of frost at night. The fruit set, you may syringe the trees with 2 ozs. of soft soap dissolved in a gallon of water, applying it in the evening, and syringing in the morning with clear water. Keep the trees well supplied with water at the roots, and apply a top-dressing of rich compost to the surface of the pots or border.

FRUITING PINE PLANTS (*Idem*).—If you now obtain fruiting Pine plants it is probable that if strong fine plants they will fruit this summer; but we could not say when unless we saw the plants. They will not require potting now. If they do not show fruit before August, or are not then showing, you may pot them but without much reduction of the ball, merely taking off the lowest leaves, potting lower, and removing any of the soil not occupied with roots.

ASPHALT GARDEN WALKS (*Robt. Orton*).—Sift the ashes when dry with a half-inch sieve, form them into a heap like those which bricklayers make in mixing mortar, make a hole in the middle, and into it pour boiling coal tar. Mix to the consistency of mortar, and when cool put the mixture to the thickness of 3 inches where the walk is to be. The ground should previously be made level and of the desired form, keeping it highest in the middle to throw off the water, and it should be made so high next the grass or soil that when the asphalt is put on it will be level with it or very little below it. Put on the asphalt when the ground is dry, and after the surface has been made even sprinkle it with enough spar or fine-washed gravel to give the walk the appearance of being of gravel. When the asphalt has become firm enough to bear the roller, roll it well and make it quite firm. Avoid walking upon it until it has become hard. In a few days it will become very solid.

BANANA CULTIVATION (*R. H. A.*).—The Banana can be, and is cultivated in England successfully in most large establishments. It requires a house with a temperature of from 50 to 55° at night in winter, and one of from 60 to 65° by day from fire heat. In summer it should have a temperature of from 60 to 65° at night, and 75° by day, with a rise of 10°, 15°, or 20° with sun. In winter it should be kept rather dry at the root, but not so dry as to affect the foliage; but when growing it can hardly have too much water if the soil is open and the drainage good. Liquid manure may be given copiously and at every alternate watering. A moist atmosphere should be maintained by frequently sprinkling every available surface with water. Air should be freely given, but not so as to cause cold draughts. For compost turf should be taken from a pasture where the soil is a good, rich, but not strong loam, cutting it 2 inches thick; place it in layers, first a layer of turves, and then a layer of fresh cow dung or sheep droppings an inch thick, then turf followed by dung, and so on, the turf being placed grass side downwards. This in three months will form an excellent compost, and should be chopped with a spade roughly, adding about one-sixth of sharp sand.

SELECT CONIFERS (*W. G.*).—*Picea nobilis*, *P. Nordmanniana*, *P. pinsapo*; *Abies Douglasii*, *A. polita*; *Thuja Lobbi*; *Thujaopsis borealis*; *Welling-tonia gigantea*; *Pinus cembra*, *P. excelsa*; *Cupressus Lawsoniana*; and *Thuja orientalis*.

APPLYING MANURE WATER TO LILIUms (*Idem*).—When they are growing freely liquid manure may be given to these plants at every alternate watering. The best that we have tried is made by pouring thirty gallons of water over a peck of sheep droppings, stirring it well up before using it. Half an ounce of guano to a gallon of water makes a very good liquid manure, which may be applied once a week.

NEPETA TETRACOLORATA (*W. H.*).—We have not tried this *Nepeta* for bedding purposes, and do not think it would prove suitable as an edging, it being of stronger growth than *N. napolitana*, and not so compact; the flowers, however, are more deeply coloured. Flowering profusely from July to September, it might be useful as a bedding plant.—G. A.

ROSE TREES INFESTED WITH APHIS (*Rosa*).—The best means of ridding plants of the green fly or aphis is to dust them with ground tobacco, applying it with a tin pepper box, which may be had of any tinman or ironmonger. The Rose trees should first be syringed with water, and then dust them with the powder, which adheres to the shoots and leaves better than were it applied to the plants in a dry state. The ground tobacco should be made from duty-free tobacco.

PICEA PINSAPPO FOR AN AVENUE (*Robt. Orton*).—*Picea pinsapo* is suitable for an avenue, but is of slow growth. *Picea Nordmanniana* is a more rapid grower. Both succeed on a clay soil, but are impatient of stagnant water.

VINES BLEEDING (*Wye*).—The best thing to stop the bleeding of Vines is Thomson's styptic. The Vines should have been pruned earlier, and then the bleeding would have been less, if not altogether prevented.

POTATO FOR LIGHT GARDEN SOIL (*Idem*).—The Lapstone is a first-rate Potato for light soil, and a good cropper. If you require a winter sort Arrowsmith's Seedling would probably suit you.

HERBACEOUS PLANTS FROM SEED (*N. E. H.*).—You may sow the following from now to July, but the earlier the better. They should be sown in pans or shallow pots well drained, placing over the drainage a layer of the roughest parts of the compost, which should be sifted. The compost may consist of two-thirds fibrous loam and one-third leaf mould, with one-sixth of sand. Fill to within half an inch of the rim, or nearly to the top if for small seeds, level the surface, and sow the seeds rather thinly, covering them very lightly with fine soil. None should be covered with more than a quarter of an inch of soil, and some with less, accord-

ing to their size. Place them, after giving a gentle watering, near the glass in a cold frame or pit, and keep moderately close, and shaded from powerful sun, so as to have the soil constantly moist, and yet avoid heavy waterings. When up keep the seedlings near the glass and admit air freely, attending well to watering; and when large enough to handle prick them out in a well-prepared bed in the open air, shading from sun until they become well rooted. In the autumn, or early in spring, move them with a ball of earth to where they are to remain. We name them in alphabetical order:—*Alyssum saxatile* compactum, *Aconitum coronaria*, *Antirrhinum majus* vars.; *Aquilegia caryophyllodes*, *glandulosa*, *sibirica*, *rosea* violacea, *Skinneri*, and *Wittmanni*; *Arabis alpina*, *Aubrieta deltoidea* grandiflora, *A. græca*, *Bellis perennis* double vars., *Campanula carpatica*, *C. carpatica* alba, *C. pyramidalis*, *Commelina colestis*, *Dolichium formosum*, *D. grandiflorum*, *D. Heidersoni*, and double vars., *Digitalis gloxinoides*, *D. purpurea* and its white variety, *Lathyrus latifolius* and white variety; *Lupinus arboreus*, *L. polyphyllus* and white variety, *Lychnis chalcedonica*, *L. chalcedonica* alba, *L. Haageana*, *L. Sieboldi*, *Lythrum roseum* superbum, *Myosotis azorica*, (*Oenothera macrocarpa*, *Oxalis tropæoloides*, *Pentstemon gentianoides*, *coccineus*, *Murrayanum*, ovatum, pulchellum violaceum, and *Wrighti*; *Phlox decussata* varieties, *Potentillas*, *Primula cortusoides*, *Pyrethrums*, *Saponaria ocyroides*, *Silene Schaffa*, *Rocket*, purple and white; *Wallflowers*, *Sweet Williams*, *Pinks*, *Carnations*, *Picotees*, *Hollyhocks*, *Brompton Stocks*, and *Canterbury Bells*.

PLANTING A VINE (O. P.).—We should not hesitate to put the plant out this year, but we would not do so until June, yours being an outside border. You may then plant it out, as the soil will have become warm, spreading out the roots and giving a good watering. The foliage should be shaded from bright sun, and the house kept close and moist until the Vine recovers from the planting, then expose it fully. You will gain a year by planting in June.

PRUNING CACTI (A Somersetshire Curate).—You may cut out the old stems, leaving the best growths. They are improved by thinning out the old bare growths, otherwise the pruning of Cacti is not to be recommended. Do not shorten the young growths, nor those of some years' growth, but merely thin them out if too close together.

LATE KITCHEN APPLES (C. N. B., Llanelli).—*Alfriston*, *Beauty of Kent*, *Dumelow's Seedling*, *Northern Greening*, *Royal Russet*, *Hanwell Souring*, *Winter Pearmain*.

FORCED STRAWBERRIES (J. W., jun.).—The *Marguerites* were very fine,

weighing 1 oz. and three-quarters of an ounce each, and excellently flavoured. Our correspondent says he finds this variety one of the best for early forcing.

SLATE EDGING FOR BEDS.—"E. T." wishes to know if slate edging can be procured for beds in the place of Box or Grass edging.

ALLURING ROOKS—Dog Violet (A Mourner).—No bird is more obstinately whimsical in selecting his nesting place than the rook. "It's no use, ma'am," said an old forester, "if they prefer a birch broom they'll build in that rather than in them Elms you wishes them to take to." We have known a nest of young rooks moved into a tree some distance from a rookery. The old birds followed it, and the next year rooks built in that tree. The same result was obtained by having rooks' eggs hatched by magpies in the magpies' nest. *Dog-Violet* seems merely to mark inferiority, and is so prefixed to show that it is not so meritorious as the fragrant species. The *Dog-Rose*, *Dog-Chamomile*, are similarly inferior to the plants of the same name without the prefix.

MANURES NOT ORDERED (A Constant Reader).—Continue to refuse to receive the box, and tell the railway officials to return it to the Company.

VARIOUS (A. B., Everley Lodge).—We are of opinion that rust on Grapes is caused by cold currents of air passing suddenly over the berries that have been shut up in a warm moist atmosphere; but too many skilled men differ upon the subject for us to venture to speak authoritatively. The "warty" appearance of the Vine leaves is really a consequence of vigorous root-action. Your Mushrooms are attacked by the parasitical fungus mentioned by Mr. Berkeley, as noticed in page 222. It renders the Mushrooms unwholesome, probably poisonous.

NAMES OF PLANTS (A Gardener).—1, *Franciscea eximia*; 2, *Polystichum angulare*, (*Rustic*).—*Antirrhinum* (common garden sport), and *Peperomia elustefolia*, (*T. P. Fernie*).—*Scopolia carniolica*, (*A. H. D.*).—*Polypodium vulgare* (common condition). (*B. C. H.*).—*Astilbe (Hoteia) japonica*, (*J. S. Gordon*).—1, *Polystichum angulare*; 2, *Adiantum* sp.; 3, *Adiantum atropurpureum*, ovatum, *Doodia lunulata*; 5, *Aspidium aculeatum*; 6, *Pteris*; 7, *Abutilon striatum*. (*J. S. E.*)—1, *Cheilanthes hirta*; 2, *C. lendigera*. The *Coccoloba* may be obtained through any nurseryman who advertises in this Journal. (*H. M. K.*).—*Pteris hastata*; *Lustrea Flix-mas* (garden variety). (*P. J. N.*).—Your flower is *Fritillaria meleagris*, a native of England, and popularly known by the various names of *Chequered Tulip*, *Snake's-head*, and *Guinea-hen Flower*. (*M. C.*).—*Orbanche elatior*, or *Tall Broom Rape*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending April 14th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

REARING POULTRY PROFITABLY—DORKINGS ABOVE ALL.

A CORRESPONDENT, "R.," wishes us to condense many former numbers, to give all the instructions for improved poultry from Ireland, for profitable poultry everywhere.

"So long," said the quack doctor, "as there remains one person unconvinced of the efficacy of my pills, so long is it my mission to preach their merits." It was a long job, and so is ours. We thought we had said all that could be said on profit-making by poultry, and that every one had read it. It appears not, and we therefore begin again.

Let us begin with "R." "I have spared no expense to secure the best birds to be had at the Royal Society's Shows. I have the following breeds—Dorkings, Dark Brahma Pootras, Buff Cochins, and Black Spanish." We will tell "R." what struck us when we read this. Comparing the pursuit of poultry to a lifetime, we thought of an old proverb—

"Did youth but know what age would crave,
How many a penny it would save."

When "R." speaks of "availing herself of the experience of others, rather than risk her own inexperience," it tells us of heavy prices paid, and that have to be returned before the balcyon days of profitable poultry begin. We fear that she begins very expensively, and must sell both show and table birds before any return will be seen.

Profitable poultry, if the market is the dependance, should be Dorkings. After every experiment this breed reigns supreme as a table fowl. The French varieties are good, but they are

non-sitters, and they have black legs; Cochins and Brahmas are hardy, but they lack breast, and have yellow legs; Spanish are delicate to rear, and they have black legs. They, too, are non-sitters.

The Dorking is not difficult to rear, it has a full breast and white legs, is apt in fattening, is an average layer, is an excellent sitter and mother—in fact, has all the attributes of usefulness in itself.

But, having the stock, you must turn it to account. Rear some early chickens of each breed, and then, if you depend on supplying the market, put all your Dorking eggs under the other hens, and sell theirs. If you can advertise them as from birds that have taken prizes, you will be able to sell them for sitting. This will be profitable. From each breed hatch some early chickens. They are worth much more than late ones.

Like William Cobbett, we wish to be very plain, not only to write so that we can be understood, but also so that we cannot be misunderstood. We would not be thought to be speaking lightly of other breeds. They have their merits. They are hardy, and do not consider weather. They are not particular as to food, but they require plenty of it. They are good layers, and if eggs only were required you might keep them advantageously; but for table purposes, in any market Dorkings will make a return of thirty per cent. more for their food than any other breed.

It is a mistake to say people are not so particular. We have never met with any of those unsophisticated places where food was food irrespective of quality; and we are quite sure from long experience, that where Dorkings can be bought for the table, other breeds will only be saleable when no Dorkings are left for sale. We are speaking of local markets; but when we come to the general mart in London, we have to do with those rules which, having for object to increase the value of

goods, should be studied by every one interested in the subject.

We must take it for granted the birds are young and well fattened; then the killing and packing come in order. The necks of poultry should be broken, the birds picked while warm, and the body being placed in a proper position, thighs brought back, and legs doubled down, it should be allowed to stiffen in that form. As the poultry sent from Ireland to Leadenhall has to compete with that which is killed in the home counties, and as freshness is a great desideratum, advantage must be taken of everything that is favourable to it. It is, therefore, necessary that the bird should be thoroughly fasted before it is killed. It should be kept *totally* without food or water for the previous twelve hours. It will then keep well to reach London.

Dead fowls should be packed in wicker or osier baskets; they should be laid in rows on stiff wheat straw; they should be covered with the same, so that it may form a layer between them and the next row. Next, they must be sent at the time when they make the best return—that is, in the spring of the year, from March to June.

Dorking fowls fattened, killed, and sent to London young and fresh, packed as we have described, and sent in the spring, will be "profitable poultry."

PACKING EGGS—HATCHING—SWINDLING.

SEEING a week ago a communication from "L. B." regarding the evil effects of packing eggs in bran, I have thought it well to say a few words on the subject, as this substance is of all others in the most general use. I quite agree with your correspondent that of all materials perhaps the very best is soft dry moss, but few of us are able to obtain it. Like "L. B.," also, I have from time to time had eggs broken which came to me in bran, and hence for some time I gave it up; but the cleanliness, handiness, and other qualities of bran make it so much more convenient for most persons, that I was led to look into the causes of non-success, and now pack eggs in it with hardly a failure.

I have found that if bedded loosely in bran, the eggs will always rise towards the top, but very seldom do so if the packing be rammed in tightly, and the box will be found to contain very much more than could be expected if so rammed down. The safest way, however, is to put in first a layer, which when pressed down will be about an inch deep, and cover this with a piece of stout paper the size of the box; on this more bran should be placed in which the eggs are bedded, another sheet of paper put on, and above the paper a third layer of an inch deep. The use of the paper is obvious—the eggs cannot be forced above or below the sheets by any means, and since I adopted this plan I have seen no need of a better. The top and bottom layer may consist instead of bran, of hay, chaff, or bran and chaff mixed, which latter indeed forms a better material for the whole; but bran alone answers perfectly thus guarded, and is the most portable and cleanly material which can be kept about, besides forming part of the regular poultry stores in most establishments. It is, however, very important to pack tightly, and the plan I adopt is to cut sheets of stout paper to the width of the several sides of the box, and place them up the sides, projecting some inches upwards. The bran or chaff can then be piled on an inch or two above the top of the box, and pressed down, the paper keeping it from running over, and at length the overlap can be folded neatly over, and will keep all within bounds, without spilling a morsel.

Another way of keeping eggs from rising is to screw them up in paper in such a way that every egg has a little "screw" an inch long both at the top and bottom. This will act as a spring, and keep the egg in place, but is not so certain as the other.

With regard to hatching eggs, failure is frequently attributable to other causes than either packing or dishonesty. My own hens' eggs till quite lately have not often given more than four out of ten (it will be seen I am not seeking to puff them), and I should have attributed this to packing, but that my own success has been about the same. The fact is, that with large cocks of large breeds, such as Brahmas or Cochins, early eggs are very seldom so fertile as eggs laid later in the season; while from a smaller bird I am using, on account of his beautiful points, nearly all have hatched. Matters are coming right now; but the rule holds good generally, and it is practically the price you have to pay for getting size and early chickens.

I have also, this year, found an unusual number of chicks which have died in the shell at apparently about a week old. I have many complaints from correspondents that they have found it a very bad hatching season, and not very long since had a letter from our most successful exhibitor of Partridge Cochins stating that he had not hatched a single chick from his first ten hens! I should hope few of your readers are quite so badly off as this, but it will be interesting if some of them will let us know how matters stand. The fact is, that in cold weather eggs are very much more easily chilled than many people believe, and that what would be called a fairly steady sitter will in early spring fail if the weather be cold. In such weather even half an hour's absence from the nest is too long, and I am quite certain often proves fatal, though double that time will not kill the chicks in the eggs in May.

Now for "J. L. L." and his boiled eggs. We have all heard of these things before, and we shall hear of them again until some one has the manliness to enforce the penalty. "J. L. L." has recovered his money, and therefore the knave will "keep the pot boiling" with impunity. I venture to ask, Has "J. L. L." done his duty? Having clearly ascertained that there is a scoundrel who can boil twelve eggs, and then sell them for 12s., he publishes it in "our Journal"—but why? Was it to recover his 12s.? or have not we, its other readers, a moral right to the rascal's name, that he may be metaphorically kicked for the dirty deed, and others cleared from unjust suspicion?—NEMO.

JUDGING GAME FOWLS.

In awarding the cups at exhibitions, judges are too prone to give them to stags, or cockerels, and to pullets, instead of to full-grown birds, and at the last two Birmingham Exhibitions cups were given to stags at the last Show, and to pullets at the last Show but one, when there were full-grown birds of equal merit there exhibited; and in the opinion of the best judges the full-grown birds are more entitled to cups than any birds not full-grown.

In Brown Reds, prizes now go too much to the willow-legged cross-bred birds with red combs and faces, which are bred from Black-breasted Reds and Duckwings, instead of to the pure-bred, blackish-legged, gipsy-combed, true Brown Reds. Prizes also go too much to the black-bodied Brown Red hens, which is excluding the original type—the Dark Brown hens with the streaked and pencilled bodies, backs, breasts, and wings, and dark red necks, instead of yellow necks, which are certainly the most beautiful specimens of the Brown Red hens, if with gipsy combs and faces. Some judges fancy that only the black-bodied hens are true-bred, and that the pencilled, streaked birds are crossed from the Partridge hens, which some are; but this cross is easily discovered by the lighter or willow-tinged leg, the lighter eye, lighter beak, and lighter neck-hackle, and redder comb and face; whereas, the true Brown Red hens show none of these signs. Brown Reds should be essentially the Dark Brown Reds in both cock and hen, as their name clearly denotes. The black-bodied Brown Red hens, if with black breasts, not streaked, which some have, are crossed with the old breed called the "Black Reds" (not the true Black-breasted Reds), and such hens when black-breasted will throw black-breasted cocks, at times very dark in colour, almost black, with blackish wings and breasts, which the true Dark Brown hens will not do. The true-bred, streaked-breasted, pencilled Dark Brown Red hens will throw cocks with both clear red-brown brick breasts, and also with the brown-streaked breasts, but such hens as throw black-streaked-breasted cocks, are from the Black-breasted cross invariably. Black-bodied Brown Red hens have been produced from the original type by continued domestication, as the wheaten and fawn-breasted Dark Brown hens have originated in like manner from the true original Partridge hen in the Black-breasted Red breed. The pencilled or streaked Dark Brown Red hens, very dark though never black, with streaked breasts, are the original and primitive strain, and will throw both to the Ginger Brown Reds and also to the black-bodied hens, thus throwing both ways as the strain may incline. The willow-legged Brown Reds, though often fast birds, are only cross-bred, and being bred from softer birds, can never be so hard, or so game, or so good, as the true-bred, blackish-legged, Brown Red are, as the willow leg is well-known to show softness, while the true dark or black leg is equally well known to be a sign of hardness. Nor does the true Brown Red plumage show itself so much in the yellow-

skinned, willow-legged Brown Reds, as it does in the true white-skinned, black-legged birds.

In Duckwings prizes are too often awarded to birds that show they are not pure-bred, such as hens with brown on the shoulders and wings, eyes not red, and coarse red breasts, all which defects generally go together, and should disqualify such birds for prizes, which should only be given to the pure-bred and beautiful bluish Silver-Grey hens, with the delicate pale silver-fawn breasts. Red-backed Duckwing cocks are also impure.

In the Piles, many judges persist in giving awards to the yellow-skinned, yellow and willow-legged Pile Game, instead of to the old white-skinned, white-legged, true-bred, hard and Game Piles, which are the real old fighting breed of the Piles, and the game birds.

The Black-breasted Reds seem to be the best judged birds at our exhibitions, as a general rule. I think far less fault seems to be found with the awards in this class than in any other at exhibitions, though the prize Partridge hens are often too pale in colour or not red enough, and their necks too pale also. Mr. Hindson, of Liverpool, and Mr. J. P. Smith, of Worcester, ought to be, and no doubt are, excellent judges of Game fowls, as are others of the Birmingham Judges, especially the old Game Judge, Mr. Thomas Chalton, who is said to be the best and most practical Judge of Game fowls in England, but many others are no doubt equally good. Game fowls, though numerous, were, perhaps, scarcely so good as usual at the last Birmingham Exhibition, as, if they had been, stags would not have won the cup, for when adult birds fail in getting cups, it is, I think, usually a sign that the show of birds is scarcely "up to the mark." I must say that I think it is wrong at exhibitions to let willow-legged red-combed Brown Reds supersede the old gipsy-combed, black-legged, true-bred strain, and also wrong that the old true-bred, white-legged Piles should be superseded by yellow-skinned, yellow and willow-legged Piles of inferior courage. I object to both yellow-skinned Brown Reds and Piles, as cross-bred, mongrel, and bastard breeds of their colours, and much prefer the original type of each of these two sorts of Game fowls. I also object to pens of single hens and pairs of hens, as useless, and to large, heavy Game fowls, with the narrow, falling, or drooping tails.—NEWMARKET.

POULTRY-KEEPING.

My *début* on this side of the channel. Hitherto the Journal has had charms for me only so far as the gardening portion of it is concerned, and the leaves of the latter part have remained uncut—not that I was quite an ignoramus on the subject of fowls or bees; but I never could see what fun it was to those little boys who will flatten their noses against the pastrycook's windows, while the tempting treasures within are as inaccessible to them as if they were the golden apples of the garden of the Hesperides; and so, as I could keep neither one nor the other, I have allowed this portion of the Journal to pass untouched. The case is now different. The scene of my future labours as a pastor will be a quiet country village, where bees and poultry will be amongst the possibilities, and I want to know what would be the most desirable and economical stand to go in for. I used, when I did keep poultry, to have Spanish, but although they were very beautiful, I could never see that they paid. Indeed, my good brother still adheres to them, and people laugh at him, saying the eggs cost him a guinea a-piece. I do not think they quite cost him that, but still I do not think them profitable; moreover, I always found that after a while the white face became discoloured, and the beauty of the birds became somewhat disfigured. What, then, is to be the sort? I incline to the Grey Pouter, but here, again, do not they become "gouty"? I never kept them, but fancy so. Cochinchinas I think an abomination, although here, doubtless, I am an ignoramus and a heretic, but we cannot help our tastes sometimes, and I do not see beauty in these great long-legged giants of the poultry-yard. I confess to having been struck with the article on barndoor fowls in a recent number of the Journal, as I can readily imagine that such a cross as there recommended would be a profitable sort, but then it is not "*pur sang*," and I rather incline to thoroughbreds whether in fowl or flowers, still, I think I should like to try them. Are not the Bolton Greys good layers? and supposing that I kept both sorts—that is, the barndoor fowls and the Bolton Greys, and had two hen houses, should I be likely to keep the breed distinct? and one other question I would ask, If I decide on com-

mencing with this stock, where shall I procure them most conveniently to my new abode, near Ashford, on the South-Eastern Railway?—D., Deal.

BUCKWHEAT AS POULTRY FOOD.

My experience of buckwheat as poultry food is exactly the same as "Nemo's." Since Christmas my fowls have had a mixture of buckwheat, Indian corn, and barley, and they always pick it up in the above order. My supply of eggs has been very good, which I attribute to the buckwheat. It is also by weight about the cheapest grain that can be obtained.—PHILIP CROWLEY, *Culverton House, Alton.*

DETERIORATION OF FANCY PIGEONS—ALMOND TUMBLERS.

POUTERS, all about Pouters, for many weeks there have been articles in "our Journal," but at last other varieties of Pigeons are mentioned.

Mr. Volekman says that most of the varieties of the "fancy" Pigeon have deteriorated in many of their qualities. Mr. G. Ure, in not a very courteous manner, bluntly denies this, and quotes the Glasgow and Birmingham Shows in proof. I have never seen the Glasgow Show, but I have the Birmingham from the commencement, and also many other large shows, and I must decidedly side with Mr. Volekman. Though the number of pens of Pigeons exhibited last year was in excess of former years (putting imported birds out of the question), in nearly every class I saw no advance, and in many cases they were not so good as I remember to have seen many years ago. True, some classes were strong in numbers, but in my opinion they were weak in quality. I believe this has arisen in most instances from many of the best birds having been bought up for some time past at high prices by persons totally deficient in the skill required in the breeding of Pigeons, and for the sole purpose of taking as many prizes as possible; and thus the birds have been worn out, and some have died of neglect or improper treatment. By these means several of the best strains of many of the varieties have been entirely lost. I am sorry to say that I know of several instances where such has been the case.

The Almond Tumbler is one of the breeds mentioned both by Mr. Ure and Mr. Volekman. I remember well the birds of Messrs. Hardy, Lucy, Pyne, and various other gentlemen; theirs were the true Almond Tumblers, having the true Almond ground, with the other colours finely intermixed, beautiful as a carnation in the marking. I remember the large full-made heads of the birds, with their eyes like pearls, and their gold-lined beaks. I remember at the private shows in London years ago, seeing many of these birds; they are not only fresh in my mind, but I find them so in the memory of others, and not at any of the great or small shows have I seen such of late. Most of the birds exhibited are wrong in the ground colour, being of a dull reddish tint instead of the rich yellow of former days; many of these birds also have not colour in their tails, &c. This is fatal to an Almond. I own there are still a few good ones about, and these few seem to go the round of the shows, and must afford gratifying results in the way of prizes to their owners. To me it seems that exhibitors forget that in the Almond class the birds must be pure Almonds in colour, and if not up to the standard they are only fit for the Tumblers of Any other colour class (if there be such); and the qualities of head, beak, eye, &c., will avail them nothing in the Almond class, as they are not Almonds, and it is for Almonds that the prize is given, and not Splashes, &c.; and also for a pair, not a dark cock and light hen, but the best matched pair. I mention this, as I seldom see an evenly-matched pair at any of the shows.

Now, if there are as good birds as ever, where are they? I do not see them at the large shows; but, perhaps, there may still be some in the hands of gentlemen who do not care to send such delicate and valuable birds from home; but when Mr. Ure says the large shows exhibit a decided advance in the Almonds and also other breeds generally, I beg most respectfully to differ from him. I say respectfully, because I do not wish to use my opinion in an offensive way; and though I differ from him, I wish to do so in as courteous a manner as possible, and I sincerely trust that all further controversy in the matter of Pigeons will be so carried on, though I can scarcely say that it is so at present.

If wished by any fancier that I should point out the breeds that I think are keeping their ground and those that I deem are losing it, I shall be happy to do so on some future occasion. —HARRY.

[Be assured that your comments will be acceptable to all Pigeon-fanciers.]

WOOLWICH, PLUMSTEAD, AND CHARLTON FANCY RABBIT SOCIETY.

THE half-yearly Exhibition was held on the 6th inst., at the Society's Club House, Beresford Street, Woolwich, when there were shown some of the finest specimens ever exhibited. One doe belonging to Mr. A. Carey, was worthy especial notice, its weight being 13 lbs. 9 ozs., and she had not attained her eighth month. She took three prizes. We must also notice another doe reared by Mr. A. Carey, which weighed 16 lbs. 9 ozs.

LIST OF PRIZE RABBITS.

Owners.	Colour.	Sex.	Length of ear.	Width of ear.	Weight.	Age.
					lbs. ozs.	m. d.
*Mr. A. Carey's	Tortoiseshell	Doe..	21½	5½	13 8	7 29
Mr. Vallom's	Tortoiseshell	Buck	20½	5½	9 4	7 29
Mr. Skinner's	Yellow & White	Doe..	20½	4½	9 8	6 29
Mr. Walklin's	Black & White	Doe..	19½	4½	10 1	7 14
Mr. Olley's	Black & White	Buck	19½	4½	6 4	3 29
Mr. Dawson's	Yellow & White	Doe..	18½	4½	7 1	4 21
Mr. Burrell's	Yellow & White	Doe..	18½	4½	8 2	5 11
Mr. Thompson's	Tortoiseshell	Doe..	18½	4½	9 12	8 0
Mr. G. Carey's	Blue and White	Doe..	19½	4½	8 5	6 13
Mr. A. Carey's	Grey and White	Buck	19½	4½	9 10	7 29

* This Rabbit took the weight prize under eight months, also the width prize, being the widest exhibited.

THE EGYPTIAN BEE.—PART VII.

HOW IT HAS FARED SINCE I TRANSMITTED IT TO AMERICA.

In page 39 of the twelfth volume of "our Journal," I related how I had been applied to by the Rev. L. L. Langstroth, who was desirous of introducing *Apis fasciata* into America. In consequence of this application I imported a second queen from Herr Vogel, placed her at the head of a hybrid stock of Italians, and despatched the entire colony to Liverpool, thence to cross the Atlantic, on the 21st of October, 1866. Of its safe arrival in the United States I was advised by Mr. Langstroth in due course, and early in 1867 that gentleman thus writes in "The American Bee Journal," under date of the 10th January in that year.

"I cannot close this communication without paying a deserved tribute to Mr. Woodbury, for the admirable manner in which he prepared a colony of bees with an Egyptian queen expressly imported by him for me from Vogel's apiary. Although the bees had been detained nearly a week in the Custom House at New York, I found on opening the hive at Brooklyn, that they had suffered little, if at all, from their long confinement, few more, if any, having died than would have perished had they remained on their stand in his apiary. The arrangements for giving the bees air were excellent, and the devices for preventing the combs from being broken were superior to any I have ever seen."

Having, therefore, received this colony intact, and obtained another Egyptian queen through the kind offices of the Rev. Mr. Kleine, of Luethorst, in Hanover, Messrs. L. L. Langstroth and Son, with business-like promptitude, immediately advertised under date of November, 1866, to the following effect:—

"Egyptian Queen Bees. Having received choice queens of this variety from the Berlin Society of Acclimatisation, which imports them from Egypt, we shall be prepared to fill orders for them next season. For circular and price list send," &c.

This advertisement seems, however, to have been at least premature, as may be inferred from the following communication addressed to the editor, which appeared in a recent number of the "Bee Journal."

"Many of our correspondents are calling our attention to the clause in our circular for 1867, in which, speaking of *Apis fasciata*, commonly termed the Egyptian bee, we say, 'We can speak warmly of their great beauty, and will give the public our judgment of their relative value, when we have subjected their claims to a thorough test in our climate.' It seems to

be expected that this report can now be made. Owing to a peculiar combination of circumstances such is not the case.

"We received in November, 1866, two distinct importations of these bees. Their coming had been delayed until we had given up all expectation of their arriving that season; and we had consequently no colonies prepared for the reception of the queens. They arrived late in November, and it was several days later when they reached our apiary. The weather was unusually unfavourable even for December; and some of the queens perished from exhaustion long before they could be introduced. Others were not to be found when the stocks to which they were introduced were subsequently examined. As our order for another supply of queens raised in 1866, and thoroughly tested, had already gone forward to the Berlin Society of Acclimatisation, the queens to be shipped in April, 1867, we still hoped to be able to breed and test this variety last season, though we returned all monies received by us on order for Egyptian queens. But we found it impossible, although having a personal agent in Europe, to expedite matters in the least. Herr Vogel, who breeds these bees for the Society, was absent in Egypt during part of the season, and we did not succeed in getting our importation of 1867 in time to breed from them to any extent last fall. We are, therefore, able to say little more about *Apis fasciata* from personal knowledge than we could have done a year ago. Those apiarists who are expecting a report from us in regard to the merits or demerits of this variety in any or all points, must consequently await the results of another season's operations.—L. L. LANGSTROTH AND SON."

Further particulars are given in a letter which I have just received from Mr. Langstroth, who, I regret to learn, has been for some time laid up from ill health, and who, speaking of the Egyptian queen which I sent him, says:—"After I reached home I found that beautiful queen gone, and have never been able to ascertain what could have happened to her, as she was in prime condition when I left New York, and her colony all right when examined here. I also lost all those imported directly from Vogel, which came in miserable condition. We had four queens last season from him; two died, and the other two were hybrids. We have now ordered others from a different party, determined to test this variety in America. Thus far we have not found them peculiarly irritable."

It does seem almost heart-rending that this queen, which appears to have been about the only one that reached America in good condition, and which, originally bred in Germany, had escaped the dangers of a journey, first to England, where she encountered the risk of being placed at the head of an alien colony, and then to America, only to perish miserably just as she had reached the end of her wanderings; but I think I can make a shrewd guess at the manner of her disappearance, and possibly afford a hint for Mr. Langstroth's guidance in his future dealings with such "kittle cattle" as Egyptian queens. Unlike the portly Italian monarchs, which are so little disturbed by a sudden transition from the Cimmerian darkness of the hive's interior to the full glare of the noonday sun and the curious gaze of the apiarian, that they will sometimes actually perform their duty of oviposition whilst the comb upon which they are standing is held suspended in the hands of the operator, Egyptian queens endeavour in every way to elude his scrutiny, and being generally too heavy to take wing, will often quit the combs altogether, and remain with a few stragglers in the empty hive. In Mr. Langstroth's case, however, the season was so far advanced that egg-laying must have been entirely suspended, and the queen being therefore slender, and in fine condition for flight, probably took wing without his perceiving it immediately upon being lifted out of the hive. Had he, when he first saw her at Brooklyn, adopted his usual precaution of clipping her wings, this catastrophe might in all probability have been averted.

It would appear, therefore, that the attempt to propagate the Egyptian bee in America having resulted in complete failure both in 1866 and 1867, Messrs. Langstroth are now exerting themselves to retrieve their misfortune. They have my best wishes for their success, but in the meantime the enterprise is being taken up by others, since we find in the Albany "Country Gentleman," that Mr. Ebrick Parmby, of New York, who has assisted Messrs. Langstroth in their importations, has received two nuclei on his own account, and, in conjunction with Mr. W. Cary, of Coleraine, Massachusetts, undertakes that "every exertion will be made to breed them in purity, which will be done in an apiary five miles from his (Mr. Cary's) Italian stock."

Mr. Langstroth furnished to the "Bee Journal" my first six articles on "The Egyptian Bee," which are copied and duly acknowledged as being taken from "our Journal," but the wind-up in which I describe the ferocity of my whilom *protégées*, and the satisfaction with which, after stiling the last colony, I trod in the earth over their grave, does not appear to be in accordance with the editor's ideas, for insertion is at once given to the letter from Mr. George Fox, who from some occult reason seems never to be stung by bees, and appears, therefore, to be able to manipulate even the savage Egyptians with impunity; whilst no notice whatever is taken of the evidence of Mr. Lowe, Mr. F. H. West, and Mr. S. Bevan Fox, all of whom so unquestionably confirm my testimony. Mr. Langstroth also contributes an article from his own pen, in which occurs the following passage:—"I shall venture the assertion that Mr. Woodbury's experience in the moist and cool climate of England, the exact opposite of that of Egypt, can hardly be accepted as a proof of the bad temper of the 'children of the Nile.' All Mr. Woodbury's stocks also, with one exception, had hybrid queens, and our experience with hybrid Italians has been such as to prepare us for almost any amount of ferocity from such mixtures. None of us who have handled even the pure Italians in such damp and cool days as usually prevail in England, can have failed to notice that they are far less peaceable than when operated on in our hottest weather."

In conclusion, I may say that whilst all and sundry of our transatlantic friends have my best wishes for their success in increasing and multiplying their African *protégées*, I would yet venture a word of warning to any of them who may be inclined, even on a broiling day, to operate on a strong stock of Egyptian bees in the unprotected fashion delineated in plate xxiii. of Mr. Langstroth's book.—A DEVONSHIRE BEE-KEEPER.

ABYSSINIAN BEES.

I HAVE noticed in nearly all the letters from the newspaper correspondents in Abyssinia, that a quantity of honey is brought into the camp. I should be glad to know if this is produced by the Egyptian or any other distinct species of bee.

Having a friend on Sir R. Napier's staff, I would endeavour to have some of these bees sent home, if the "DEVONSHIRE BEE-KEEPER" or any of your readers having experience in the transport of bees, would kindly give me such particulars as would enable my friend to have them properly packed, and sent off with a reasonable hope of success.

It should be understood that the gentleman to whom I refer has had little or no experience in bee-keeping, and that it will be necessary to enter into detailed instructions from the beginning.—J. M. H.

[It is not known with certainty what species or varieties of the honey bee are indigenous in Abyssinia, nor is it possible to give detailed instructions which will enable your friend to pack bees for transport to such a distance without knowing something of the kind of hive in which they are domiciled. I would suggest, therefore, that you should first endeavour to procure a few specimens by which the species may be identified, and if possible a bit of empty comb, as well as ascertain if bees are domesticated, and if so, what description of hives are used, together with any particulars that may be obtainable of the mode of bee-keeping practised in that remote region. My best services will then be at your disposal; and if you will first communicate with me direct, I shall be happy to furnish you with a little contrivance by which specimens of bees may be sent uninjured by post to any distance.—T. W. WOODBURY, Mount Radford, Ereter.]

SILKWORM-REARING IN ENGLAND.—No. 8.

THE most suitable apartments for silkworms are those facing the south, on upper, not ground floors, free from damp, not subject to impure exhalations or sudden changes of temperature, but open to the pure air. It is customary among large silkworm-rearers to have a small room in which to hatch silkworms' eggs, transferring the worms after their second or third sleep to more spacious rooms. A small room in spring is easier to heat with less consumption of fuel. It should be lighted by a window facing the south, opposite which should be the door, entered from another room, and it should have a stove at one end, at the other a fireplace, or, better, a low hearth of the olden times. The window must be provided

with a blind to protect the worms or eggs from the sun. The centre is to be occupied by a small silkworms' castle if the worms are to be kept in the room any length of time, otherwise a stage or even a table will be sufficient for the hatching. Such a room 10 feet square would be sufficient to rear worms in from a third of an ounce of eggs, or about 15,000 in number. Several ounces will require more room in proportion; therefore, the erection of a suitable building if not already at command must have the attention of the rearer.

The best position would be the south side of a hill, at a distance from low marshy districts, and open to a healthy air; land with a dry subsoil of a porous nature is to be preferred. The building should, if possible, face the south, the entire length running east and west. I should begin by forming a cellar a third of its size, in which to keep mulberry leaves fresh and ready for use. Over the cellar, a foot above the ground, might be a room 8 feet high, having wide doors at least on two sides, to admit a current of air in which to lay out the leaves to dry, if gathered wet, as sometimes is unavoidably the case. This room would serve as a reeling place, and for a variety of purposes when not otherwise required. Above this the rearing room is to be built; and if for only two castles, adapted for rearing worms from 1 oz. of eggs, its dimensions must be at least 20 feet by 20, and 10½ feet high. For six castles the same width of 20 feet is appropriate, but the length may be less in proportion, because the castles placed three in a row, end to end, occupy only 36 feet, and reckoning 7 feet of space to spare round them at the two extremities, or 14 feet more, the entire length would be 50 feet. The first-named room will require only one stove, at the east end, and a fireplace, or a low hearth is better, at the west. There should be a door 4 feet wide in the south front, and a sash window 7 feet high by 3½ feet wide on each side. On the north one such window will suffice, but that one is necessary, not only to admit light, but at times for increasing ventilation. The larger room must have a stove at the east and west ends, one central fireplace or hearth on the north side, and one door in the south side, with a small window above it, and two windows on each side. On the north two windows, or one opposite each end castle will suffice. All the windows must be provided with shutters and blinds, also with ventilators on the south side in their bottom central panes, and on the north in the top ones, constructed all to close more or less when required.

Whatever description of stove be adopted, smoke must not escape from it into the room. The cheapest and best materials of which to construct it would be firebricks, which retain the heat better than anything even when the fire is out. Its height might be 3 feet, and the length of each side 27 inches. At the present day there are many good appliances for warming buildings. The hot air, water, or steam systems with a furnace outside would be excellent, but, perhaps, not advantageous unless for a larger room than I have named.

Some large rearers hatch silkworms' eggs by means of an apparatus placed on a table, and warmed with steam pipes from a small boiler heated by an argand fountain lamp. I fully appreciate the method as most advantageous, because this instrument is easily managed and regulated. It is a case or closet of wood, which may be a yard across each way, and 4 feet high, the front consisting of two glazed doors, one at the top the other at the bottom. Inside, within 15 inches of the upper part, is fixed a wire shelf; another may be 9 inches below it. These are for the boxes containing eggs to be hatched. The boiler, which is of tin and no larger than a common kettle, is fixed outside the case to a bar of iron connected with the case, and the lamp is secured beneath it. From the top of the boiler a half-inch or 1-inch pipe is carried through the bottom of the case and round the sides, up the back, out at the top, and down outside, again entering the boiler about one-third from the bottom. There should be at the top and bottom of the case trap doors, to be kept open a few inches for ventilation, more especially when the worms are issuing from the eggs. It is only necessary to visit this apparatus two or three times during the day and night to snuff the lamp or fill up the boiler with hot water if there is fear of reducing the temperature too much by using cold water. A thermometer is necessary inside the case in order to regulate the heat. With this apparatus in the hatching room, fire or stove heat will hardly be required unless the weather is cold, which is sometimes the case even in May.

Another simple method of proceeding is to place the hatching box containing the eggs in a common horsehair or wire sieve, set the sieve on the two front legs of a common chair

lying on its back upon a table, and place underneath the sieve a low oil or spirit lamp, the flame of which can be turned up or down without danger of going out, as more or less heat is required. Six inches above the lamp should be fixed a sheet of tin or iron a foot square to distribute the heat and prevent the flame concentrating itself too much under the centre of the sieve and so endangering the eggs. The sieve can be covered with a towel or piece of blanket upon which a thermometer may be set.

Some people place the eggs in small linen bags, putting them at the foot or head of a bed under the sheets and blankets where a person sleeps. This method I do not consider very good, any more than that practised by women on the continent of placing the eggs in their bosoms, where the heat is too great. Besides, I believe the exhalations from the body prejudicial to the worms, causing them to enter life in a weak state.—LEONARD HARMAN, JUN.

OUR LETTER BOX.

LADY DORKING'S TROUBLES.—Having half promised to find a "Children's Corner" for the following, we redeem our semi-promise.

"Cluck, cluck," said Lady Dorking,
One sunny April day;
"I feel so very broody
I cannot longer lay.
"They've taken all my eggs away,
And left me only one,
And that I'm sure will never hatch,
Because it's made of stone.
"Oh dear! I feel so broody
I don't know what to do;
Oh! what I'd give to have some eggs,
If only one or two!"
The Baron Dorking heard the noise,
And quickly came to see,
What all the clucking was, and who
It possibly could be.
And when he saw my Lady D,
He nimbly sidled up;
With head bent down, and drooping wing,
And many a tender cluck.
My lord's polite attentions, though,
Were not so well received,
My lady on the contrary,
Seemed very much aggrieved.
And turning round her swelling tail,
She raised her ruffled wings,
And said, with many an angry cluck,
Some very naughty things.
My lady thought, on being left
To sorrow all alone,
She'd go and try what she could do
To hatch her egg of stone.
So, turning round, she slowly went
Towards her straw nest,
And settled down, with many a cluck,
Upon her fevered breast.
And drawing in her egg, she gave
Herself to incubation;
And found content, in having found
Her proper occupation.
Next morning when Miss Annie came
To feed her pets, she saw,
On looking round, my Lady D
Was snugly "in the straw."
"You dear old thing!" she gaily cried,
"What are you doing there?"
Come out and have your breakfast—Why,
You're broody I declare!
"Oh fie! you naughty, naughty bird;"
Miss Annie gently said,
"To try and bite your Missie's hand,
From which you've often fed."
"But come, I think I have some eggs—
And you shall have a brood,
I'll take away your egg of stone—
But mind, you must be good."
She found a nice secluded spot
And made her up a nest;
For three weeks' absence from her lord,
She thought would suit her best.
And so my lady had her wish,
And this displays the beauty
Of trying, be it great or small,
To do our present duty.
"Tis true that like the egg of stone,
That duty may be humble;
But do it, and you'll find more joy
Than standing still to grumble.
On duty's path you'll find your wish,
For 'tis enchanted ground
Where bitters all are turned to sweets,
And toil with rest is crowned.

—B.

EGGS NOT HATCHING (*Constant Subscriber*).—The failure of eggs is a Cuckoo cry; everyone complains of it. An unimpregnated egg is clear, and will remain so although under a hen for two months. One that becomes rotten without being stale is one that has lived and died and become putrid. A stale egg is a different thing; that is the result of being kept too long. It becomes stale as meat does. Change the cock. (*T. J. K.*).—The complaint we receive from everyone now we receive every year. Of the early eggs that are laid, it is true many are clear—i.e., they are not impregnated. In the cold weather a cock confines himself to his favourites. Many of the eggs about which we have complaints now, were laid last month. Some nights there were from 8° to 10° of frost. That would spoil any egg; less than that would chill one, and that has the same consequence. Then broody hens have been very scarce. Many were put on eggs before they sat steadily and closely. They will sit well for two days, then they play with the eggs for two days, and then sit closely. Those eggs cannot hatch. When the pullets were running with the young cock it was too early; he did not notice them. Your eggs would be good from two days after the old bird was with the hens, provided he took to them. You need not be discouraged; persevere, and May will make amends for the disappointment of March.

SEPARATING COCHIN-CHINA COCKERELS AND PULLETS (*Lemon Buff*).—It is too early yet to separate chickens. It need not be done till there are indications that the cockerels will soon notice the pullets. White are as easily reared as any others.

HARE RABBITS (*Ocean Monarch*).—They are not crossed with the Hare; they would be Leporidae if they were. They derive their name from being in every way more like a Hare than a Rabbit. They weigh when full grown from 7 to 10 lbs. They are prick-eared, they do not burrow, and they are very prolific.

CRÈVE-CŒUR COCK'S SICKLE FEATHERS BROKEN (*Young Exhibitor*).—It is simply a disadvantage, not a disqualification.

SPANISH PULLET LAYING SOFT EGGS (*E. L.*).—There is no injury to the ovary, nor is the case likely to be a permanent one. It is simply a question of defective secretions. The proper treatment will be to confine her for a time, and to purge freely with castor oil till proper-shelled eggs are laid by her.

BREEDING POULTRY FOR EXHIBITION AND PROFIT (*W. B.*).—You begin with too many breeds. Four will be enough—Dorking, Spanish, Brahma Pootras, and Cochin Chinas. Give your Dorkings half the space, divide the remaining half among the other three. If you are bent on more breeds keep Crève-Cœurs and Game. You should not on an acre keep more than four breeds. Sixty fowls are enough for one acre, but with care you may keep seventy. The two acres will be wanted for the chickens. They will damage the crop one-third, or nearly half. We do not know the value of their guano. If you mean to sell chickens you will find it most profitable to sell as fast as they are fit for market, a few at a time.

GOOSE NOT LAYING (*J. Smeed*).—We cannot tell you why. It is unusual and almost impossible for a Goose to pass a season without laying. Watch her closely. It is more than probable the hen exceeds her time, because the eggs are too dry. We have had a dry time lately. If you have not done so, we advise you to moisten the eggs every day after the 15th. We think then you will not only find them come out, but they will be stronger.

INCUBATOR TEMPERATURE (*C. M.*).—Temperature for hatching, 105°. Any thermometer correctly graduated will do. The temperature may be allowed to fall 5, or even 10, for a short time, just as it does when a hen leaves her nest to feed. But this cooling must not be at the time the chickens are breaking the shell.

DUCKS RETURNED (*E. Clarke*).—You were treated most unfairly, but there are too many difficulties in the way for you to recover compensation.

HIVES (*W. E.*).—It is impossible to consider all things, so as to give a satisfactory answer to the question, "which is the best form of hive, all things considered?" without knowing something respecting the apian attainments of the querist. The best hive for an ordinary bee-keeper is a good sized one, of the common sort. The best for a bee-keeper who wishes to make a step in advance, and put on an occasional super, is a straw hive with a flat top (such as Payne's and others), and orifices which will permit him to do so, and to feed when necessary by means of an inverted bottle; whilst the best for the scientific apian is the Woodbury frame hive.

BEES DYING—FEEDING (*J. Riall*).—Your first stock evidently perished of starvation, and being only a swarm of last year, there is nothing very unusual in the absence of royal cells. The two others appear to have died of dysentery, which may possibly have arisen from the unwholesome nature of the food (ale and moist sugar), with which they had been supplied. The restless stock might possibly have lost its queen, and you may have saved it by giving the bees another; but all this is very uncertain. "Burnt" sugar is a most provoking printer's blunder, which occurred in our answer to your inquiry of the 5th of February, but which we did not discover until directed to it by your letter. It should have been "lump" sugar, which, when mixed with water in the proportions indicated, forms excellent bee food. The best mode of administering it is fully described in the bee calendar of "The Gardener's Almanack" for the present year. Frame hives enable the apian at any time to obtain a clear insight into the actual condition of his stocks, and are, therefore, by far the best if you can only manage to manipulate them. Your note, received since the foregoing was written, and in which you state that the added queen has been expelled, whilst the extrusion of a few undeveloped bees has proved the existence of the original queen, is sufficient evidence of the uncertainty alluded to.

POULTRY MARKET.—APRIL 15.

We have still a short supply, with a dull trade. If the demand were greater poultry would be unusually dear.

From observations taken near London during the last forty-one years, the average day temperature of the week is 59.8; and its night temperature 36.8°. The greatest heat was 82°, on the 27th, 1865; and the lowest cold 18°, on the 24th, 1851; and 29th, 1861. The greatest fall of rain was 1.40 inch.

FRUIT TREES ON OPEN WALLS AT THE NOTE, MAIDSTONE, THE SEAT OF THE EARL OF ROMNEY.

UCH has been said and written as to the respective merits of orchard houses, heated walls, glass casings, and last, though not least, open walls, with regard to the cultivation and successful development of many of our exotic fruits, and as any notes of successful culture combined with economy must ever be acceptable to the public, a few remarks on the wall fruit trees at the above-named place may not be unwelcome.

The kitchen garden, which is a parallelogram, running from east to west, and gently sloping to the south, is nearly 7 acres in extent, 3½ acres of which are enclosed by a wall 12 feet high, well clothed with a fine collection of fruit trees, consisting of choice kinds of Peaches, Nectarines, Apricots, Plums, Pears, and Cherries, all of which are placed with a due regard to giving each kind its most suitable aspect.

The Plums and Cherries are trained both in the fan shape and also horizontally. Fine examples of both methods of training may be seen, more especially amongst the Plums, of which there is a choice collection, not only of sorts but of specimens, some of them extending nearly 40 feet in width.

The Pears, with but few exceptions, are trained horizontally. Amongst them may be named a fine example of Gansel's Bergamot, covering 47 feet of this 12-foot wall with its beautiful tapering arms—beautiful at all seasons of the year—in the spring with its mass of blossom, in the summer and autumn with its almost invariably fine crop of fruit, and in the winter as an example of a close approach to perfection both in pruning and training. Taken as a whole this tree may be quoted as a model of what a horizontally-trained tree should be.

But it is concerning the Peaches and Nectarines that I would speak more particularly, and this brings to mind the question of orchard houses *versus* open walls; and knowing, as I well do, what splendid examples of both Peaches and Nectarines are annually produced by the trees on these walls, I cannot help feeling a doubt as to the necessity for orchard houses, at least in our southern counties. Doubtless in all the northern counties, and probably in some of the midland counties, and also in Scotland, orchard houses are a great boon to the gardener; but, generally speaking, in gardens enjoying the more genial climate of the south, and given the proper soil, good walls, healthy trees, and the requisite skill for their cultivation, I venture to affirm orchard houses may be considered an expensive luxury. They may be a very enjoyable promenade in all weathers, and they may present the fruit more agreeably to the view in all its stages of growth, but so far as the supply of Peaches and Nectarines is concerned, I think they are not to be considered as indispensable adjuncts to the garden. And surely it must be more pleasing and satisfactory for the gardener to produce, and his employer to have a supply of these

delicious fruits for the dessert without incurring the expense of a costly glass structure. Let us be honest about this. We all, doubtless, desire to have as much assistance from glass houses as possible, but if A can produce a supply of fruit in the open air, for which B, possessing equal advantages of climate, &c., requires glass, the only inference which can be drawn must be that B is simply deficient in cultural skill, or, possessing it, fails to apply it properly.

To return, however, to the trees in question. I may here mention that the whole of the Peach, Nectarine, and Apricot walls have a projecting board, level with the top of the wall, supported by and screwed on to stout iron brackets, which, passing over the top of the wall, are fastened by stout staples to the back of the wall. These boards, which are never removed, are 15 inches wide by 1½ inch thick, and it is calculated that they are put on the wall, painted, and finished complete, at a cost of 1s. per foot run.

As the treatment of one tree will suffice for the whole, I will proceed to notice what might be described as the monarch of the whole collection. This splendid tree is a Royal Kensington Peach,* and is about thirty years old. Its history is as follows:—

In the year 1845 these gardens were remodelled, and this tree, which had been planted about three years, and had made a vigorous growth, was, with many others, taken up, and its branches cut off; it was planted in the open garden, where it remained, having but very little notice taken of it, till the autumn of 1847, by which time the new walls were built, and the borders in readiness for the trees, most of which were maiden trees. As this tree, however, appeared healthy, its present position was assigned to it, and it now covers 456 square feet of wall, being 38 feet wide by 12 feet high. It has eight principal or leading branches, and is in a most vigorous state of health, having an abundance of fine bearing wood from bottom to top. I may also state that the crop of fruit taken in the years 1866 and 1867 together, gives a total of ninety dozen of fine fruit; and this year, as the fruit has set so abundantly and the tree is so vigorous, it is intended to allow it to carry fifty dozen: so that up to the present time each year has witnessed an increase of its vigour and fruitfulness.

The treatment to which this tree has been subjected presents nothing original or uncommon. The branches are all unnailed in the autumn, with the exception of enough shreds being left to keep them from being broken by the wind; this is done as soon as the leaves have fallen, which process is sometimes assisted by lightly passing a broom over them as soon as signs of decay are visible: the tree is then carefully dressed with a strong mixture of soft soap and sulphur, and it is pruned and nailed early in February. Till within the last three or four years the Nottingham netting was used to protect the blossoms and foliage from frost; this, however, has been entirely discontinued, as the projecting board is found to afford all the shelter that is required, and the netting is not now used

* I give the name by which the tree has always been called, although it may be a synonyme of *Grosse Mignonne*.

till it is required to protect the ripe fruit from wasps, &c. The foliage is closely watched, and is at once freed from any noxious blight or insect by which it may be assailed. To this careful attention to the health of the foliage, together with a vigorous root action, may be attributed in a great measure the robust health and noble proportions of the tree.

The soil of the garden is a heavy loam of an average depth of 3 feet, resting on a subsoil, or rather a substratum, of shattery rock.

Although the borders are not of uniform width, neither are they all treated alike, some being cropped heavily, and, I may also add, manured heavily, yet it may prove interesting if I give the dimensions and treatment of the border in which the tree referred to is planted. The border is 8 feet wide, it is well manured every autumn with good rotten two-year-old dung, and is slightly forked over; in fact, this operation may be rightly termed a shallow surface-dressing, as the soil is only stirred sufficiently to cover the manure, with which a little charcoal is occasionally introduced. Liquid manure is also freely administered as the fruit is swelling. Some winter Lettuces are usually planted close to the wall, and occasionally a few flowers may be seen on the front part of the border, but nothing approaching to a crop is ever attempted. The border is the reverse of porous, being stirred as little as possible, and also having a narrow pathway at about 18 inches from the wall, which is trodden hard, and is never dug up. In front of the border, and running parallel with it, is a coal-ash walk 6 feet wide, and into the firm loamy soil under this walk the roots of the fruit trees have, doubtless, penetrated.

After having written the foregoing remarks I need hardly say that I fully endorse the views advanced by Mr. Nicholls in page 271, and I will only add, that could "OBSERVER" but see these trees, it would materially alter his views as to any debility of constitution arising from that exposure to our changeable climate which trees may be said to undergo that have no other protection than an open wall and a simple coping board.—*EDWARD LUCKHURST, Egerton House Gardens, Kent.*

HOTHOUSE BOILERS.

THE discussions which have lately appeared in the horticultural papers on the subject of boilers is a proof that opinion is much divided as to the merits of those in use, and also, I think, that there is much dissatisfaction with the working of many of them. I have for years contended that no one boiler yet offered for sale as a good one, is anything like as good as it might be.

A perfect boiler ought to burn any kind of fuel—coal, slack, or cinders. It ought to have wide-enough side flues to cause a good draught, even if the chimney be 100 feet or more from the fire. It ought to sit down to the firebars, so as to require no bricks under it. The return pipes ought to enter the boiler without passing through brickwork. Is it necessary to prove these propositions? The difference of from 7s. to 10s. a-ton in fuel is surely a great consideration. I find it so with thirteen houses heated with hot water, some of them 100 feet long. Using nothing but cobbles and slack the cost is considerable, but it would be more than doubled if coal were used. A boiler with narrow side flues will burn well if the chimney be close to the fire, but what a waste of heat there is in such a case! Why should not the flue run the length of the house? If the draught is good and no damper is used there is no danger. No wonder flues are dreaded if dampers are employed; to imprison explosive gases in a flue is to invite an accident. There are two flues here 100 feet long, and one nearly 200 feet; it is wonderful what economisers of heat they are.

That a boiler ought to enclose a fire is self-evident; when set on bricks, heat is wasted and bricks burnt away; this is more particularly the case where the flame impinges on bricks in place of striking part of the boiler. If the return pipes pass through a mass of hot bricks return currents are set up, and the flow of water into the boiler is much impeded.

Now, what boiler fulfils all these conditions? The tubular boilers so often crack, that if no other objection could be raised against them, I should decline to use them; but they require coke—an expensive fuel, are surrounded by bricks through which the return pipes must pass, and necessitate a very deep stokehole, which in wet situations entails a great expense in drainage, or, if not drained, it must be so constructed and covered as to keep out water. The saddle boiler presents a good concave surface to the action of the fire in the first in-

stance, and its sides come well down to the firebars; it will also burn any kind of fuel, but the flame wastes its power on a mass of brickwork, through which the return pipes are obliged to pass, and the side flues add little to its efficiency. To obtain as much heat from the side flues as possible, they are constructed very narrow to make the flame lap the boiler, as the bricklayers say; thus, unless the chimney is close to the fire there is a deficiency of draught.

McNab's presents a surface of iron, backed by water, to the action of the flame, and the pipes go direct into the boiler without passing through bricks—two great advantages, but it requires several courses of bricks on each side, and is too far from the bars.

The X boiler, made at Dalkeith, is, in my opinion, the best boiler out; the under surface is nearly as good as the dome of the saddle, and the side flues present a good surface above the flame, whilst from their size they will admit air enough for a long flue; in other respects it is as faulty as others, as it must be surrounded and raised on brickwork. I have for years urged Mr. Foster, who builds my houses, to bring out a boiler of his own invention, which is intended to remedy all these defects; but he has preferred to improve the X boiler, as being the least trouble to himself. In this I do not think he has consulted his own interests, but he has made the X boiler as nearly perfect as possible. Two castings containing water, and of course connected with the boiler, come down to the firebars, and a box of water is also provided for the flames to play upon, and into which the pipes bring the return water direct, at a lower level than the boiler; the fire is thus surrounded entirely by water, and no bricks are exposed to its action. This improved boiler is now at work in my new Orange house, 100 feet by 30, containing about 1300 feet of 4-inch pipes, and I could almost cook a chop on them. I am satisfied it is twice as powerful as any boiler I have, whilst it burns much less fuel in proportion to its work. I should be happy to show it to any one interested.—*J. R. PEARSON, Chilwell.*

PLANTS INHALING NOXIOUS GASES.

WHILE I fully appreciate the able comment of the Editors on my article, in page 276, there is a portion of it on which I cannot remain totally silent, inasmuch as it gives the direct negative to the very foundation of my argument—viz., that suffocation is in reality poisoning. The words which I take exception to are these, "He assumed and still assumes that suffocation is the same as poisoning. If so, the man who is hung is poisoned! Now, unquestionably this similarity is not admitted." In reply I will merely give two extracts, which will certainly show that the similarity is admitted in language most unequivocal. Gregory, in his "Practice of Medicine," says—"Death by pure asphyxia is attributable to venous blood acting as a poison. The sort of death described as beginning at the lungs takes place not only in hanging and drowning, but by cutting the spinal cord in the upper part of the neck, whereby the muscles of respiration are paralysed." The date of the work from which this extract is taken, is 1846. It was then in the sixth edition. The next extract is from "Taylor's Medical Jurisprudence." It is dated 1861, and up to that time there had been issued from the press 15,750 copies. On page 797 it thus reads—"In following common language, the medical jurist is compelled to apply the term suffocation to another variety of death—viz., that of poisoning by gases. Thus, if a person die from the effect of carbonic acid, of confined air, of sulphuretted hydrogen, or other noxious gases, he is commonly said to die suffocated. Strictly speaking he dies poisoned, as much so as if he had taken oxalic or hydrocyanic acid."

Under death by hanging in the same work asphyxia is given as the cause of death. I conclude, then, that asphyxia is suffocation, and suffocation is poisoning, and, consequently, the man who is hung is in reality poisoned.—*J. W.*

[We admit as fully correct the extracts which our correspondent has made, and as fully admit that some of the effects caused by suffocation are the same in certain instances as those produced by some poisons; but that is different from the dictum that suffocation and poisoning are identical.—*Eps.*]

THE NATIONAL TULIP SOCIETY.—The next Exhibition of this Society will be held at the Manchester Botanical Gardens on May 29th, in conjunction with the Great National Horticul-

tural Exhibition; and although the day is somewhat late for the south, the Show promises to be a great success. Admirers of the Tulip will be well satisfied by a visit to it, for the culture of this flower is carried out with spirit in this neighbourhood. We remind intending subscribers that no exhibitors' entries can be received after April 25th.

ROYAL HORTICULTURAL SOCIETY.

SECOND SPRING SHOW.—April 18th.—It has been frequently urged that horticultural exhibitions of late years have been too much alike, that the same subjects were brought forward show after show and year after year by the same exhibitors, and that nearly the only variety imported into them was that which resulted from certain kinds of plants going out of season and being replaced by others equally limited in number. There was much truth in this charge, and doubtless the decline of public interest in the horticultural exhibitions near London, which at one time threatened their existence, was in some measure attributable to the absence of new features and the little variety which they presented. Even the most ardent lover of plants became weary of seeing time after time the same stove and greenhouse plants, magnificent though the specimens were, the same Heaths, the Azaleas and Pelargoniums the same all but in kind; the interest flagged; the attendance of visitors fell off; the funds were diminished instead of augmented by the exhibitions; less and less became the amount of the prizes and the number of subjects for which they were offered, greater and greater became the sameness of the shows. The establishment of spring shows and Tuesday meetings has effected a great change, for they bring before the public a class of plants which previously, except in private gardens, they had little opportunity of seeing, the exhibition season has been prolonged by several months, and the cultivation of many plants, especially those which flower in the early months of the year, greatly encouraged. Thus at the Show on Saturday last there were beautiful collections of Anemones, the cultivation of which seems of late years to have languished in the south, being confined to only a few; but who could say, on seeing them as shown by Mr. Turner and Mr. James, that they are not well deserving of more attention than they receive? That they will—that they must—again come into favour we firmly believe. There were those old favourites the Polyanthus—charming flowers, which every one has it in his power to grow, but not every one can grow well; there were Cyclamens of surpassing beauty; and there were numbers of those plants which our grandfathers delighted in, but which have been driven out of cultivation by the more showy but less enduring bedding plants, and nearly lost—perhaps some of them quite so. Besides these, there were the Roses, the great feature of the Show, but they will always hold their own—they can never go out of fashion; a host of miscellaneous subjects; and Messrs. Lane's exhibition of spring-flowering plants re-arranged, and with its beauty enhanced by the introduction of fresh materials. All these combined to render the second spring Show at Kensington one of the most varied and excellent displays which it has been our pleasure to witness at this season. No wonder, then, that the expressions of gratification were general, and that the attendance of visitors was much more numerous than could have been expected from a cold niggardly forenoon, threatening to terminate in rain.

Roses, as already stated, were the great feature of the Show; superb specimens the most of them were, some having as many as thirty blooms, exhibiting as much perfection as if it had been the height of summer, and more of freshness. In the class for nine the competition was very close, the three collections shown being of great excellence. Mr. W. Paul took the first prize with Madame V. Verdier, splendid cherry colour; Elizabeth Vigneron, with more than a score of pink flowers, some of which were 5 inches in diameter; Beauty of Waltham, very fresh and bright; Jean Gonjon, beautiful red; Caroline de Sansal; Victor Verdier, with about a score of blooms and expanding buds; Louise Odier, rose, very full of bloom; Madame Damazin, salmon; and Céline Forestier, very fine. Messrs. Paul & Son were second, pressing very closely for first, with François Lacharme, very fine colour; Anna Alexieff; Professor Koch; John Hopper, very fine; Charles Lawson, with about three dozen blooms; Madame Villermoz; Souvenir d'un Ami; Madame de St. Joseph, with a score of blooms; and of Céline Forestier a very fine specimen. Mr. Turner, of Slough, was third with a very excellent collection, in which Victor Verdier, Maréchal Niel, Céline Forestier, and Madame Falcot, were very remarkable for the number of the blooms; the others being Leopold Hansburg, purplish crimson, Charles Lawson, John Hopper, Anna Alexieff, and Madame V. Verdier, all of which were also very fine.

In the amateurs' class the best six came from Mr. James, gardener to W. F. Watson, Esq., Isleworth, and the second prize went to Mr. Wilkie, Oak Lodge, Kensington.

For the best single specimen Messrs. Paul & Son took the first prize with President, and Mr. W. Paul was second with Comtesse de Brossard, with very large straw-coloured flowers. Mr. Turner had Madame Bravy, with upwards of twenty blooms and partially-expanded buds, but not in such perfection as he usually exhibits this beautiful Tea Rose.

In the class for twelve new Roses, first put in commerce in 1866

and 1867, there was again a keen competition. The first prize was awarded to Mr. W. Paul for Mademoiselle Annie Wood, with large and finely-shaped red flowers, bearing considerable resemblance to those of *Senateur Vaise*, and having very vigorous foliage; *Souvenir de Monsieur Boll*, very large, bright rosy crimson, free-blooming; *Madame Rival*, very double, pink; *Madame la Baronne de Rothschild*, very large and fine, peach; *Aspasie*, rosy crimson, shading off to peach; *Antoine Ducher*, very large, violet shaded crimson; *Charles Verdier*, rose; *Engène Scribe*, large, brilliant red, a flat Rose; *Gloire de Montplaisir* not in good condition; *Madeleine Nonin*, rose, not expanded; *Tea Madame Margottin*, pale yellow, very fine; and *Monsieur Furtado*, lemon, shading off to a paler colour, and altogether a finer Rose than *Céline Forestier*. Equal second prizes were awarded to Messrs. Lane & Son and Messrs. Paul & Son. The former had *Mlle. Annie Wood*, fine; *Madame Rival*, rosy peach; *Charles Verdier*, pale rose, with a salmon rose centre, fine; *Madame Margottin*; *Antoine Ducher*; *Madeleine Nonin*, rose, suffused with purplish lilac; *François Treyve*, crimson scarlet; *Horace Vernet*, velvety dark crimson; *Paul Verdier*, very fine, bright rosy crimson; *Thorin*, bright rose; *Madame George Paul*, dark crimson, shaded with violet purple; and *Tea Bonton d'Or*, small, lemon-coloured. Messrs. Paul & Son had *Madame George Paul*; *François Treyve*, fine; *Antoine Ducher*, *Horace Vernet*, *Paul Verdier*, *Charles Verdier*, fine; *Madame Margottin*; *Monsieur Noman*, pale peach; *Princess Mary of Cambridge*, *Monsieur Furtado*, *Napoleon III.*, violet-shaded crimson, and *Triomphe de Soissons*, delicate rose. Mr. Turner, of Slough, also exhibited a fine collection.

In the miscellaneous class an extra prize was awarded to Messrs. Paul & Son, for Roses in pots, among which were fine specimens of *Madame Villermoz* and *Gloire de Dijon* with splendid blooms; and Mr. William Paul had also extra prizes for a collection, and for ten boxes of beautiful cut blooms. Among these were several of the new Roses; for example, *Souvenir de Monsieur Boll*, *Mademoiselle Thérèse Levet*, pretty, pink, and *Madame Bellenden Kerr* in the bud state, white, with a blush centre, in the style of the Maiden's Blush. There were also fine blooms of *Enfant de Lyon*, pale yellow; *Lamarque*; *Princess of Wales*, crimson, with a fine glow of purple; *Safrano*; *Dr. André*, splendid; *Triomphe de Gnillet* lilac, of a coppery or salmon tinge, and deliciously scented; and, lastly, remarkably fine blooms of *Cloth of Gold* and *Gloire de Dijon*, produced by plants pruned on the spur system, like Vines, and which, judging from the results which Mr. W. Paul has already obtained, is likely to prove a decided success.

Cinerarias came next in order in the schedule, and of these the best were those from Mr. James, of Isleworth, who had neat well-bloomed plants of *Uncle Toby*, large, violet purple; *Snowflake*, white; *Lord Elgin*, crimson; *Agrippa*, white, dark disk, narrowly edged with purplish crimson; *W. Reeves*, white, edged with rosy crimson; and *Miss Smith*, white, dark disk, purplish violet edge. Mr. Fairbairn, gardener to the Duke of Northumberland, *Sion House*, who was second, had *Captain Schreiber*, light blue; *Lady Theodore Grosvenor*, white, with a broad blue edge; *Prince of Wales*, rosy crimson, with a narrow white ring round the disk; *William Dobson*, deep crimson; and *Beatrice*, white, edged with purplish crimson. Mr. Marcham, gardener to E. Oates, Esq., Hanwell, was third.

Mr. James was the only exhibitor of *Calceolarias*, and received a first prize for plants in very good bloom of the same excellent strain which he usually exhibits.

Of *Amaryllids* there were only two sets of six, one from Messrs. Veitch, which received the first prize, and the other from Mr. Williams, of Mollway, who was second. Messrs. Veitch had their new and handsomely-marked variety called *Pardina*, *Ackermannii pulcherrima*, large and showy, velvety scarlet; *Invincible*, dull scarlet, striped; *Madame Goldsmith*, very large and showy, broadly striped and feathered with white on a red ground, a very fine variety; *Belle Brunette*, not so large, but somewhat similar in character; and *Vittata rubra*, deep red, striped with white. Mr. Williams had *Regina*, bright scarlet, striped at the base of the segments; *Robusta* and *Purpurea magnifica*, crimson scarlet, the latter very dark in colour; *Graviana*, scarlet, with a white throat, good; *Johnsoni*; and *Cleopatra*, crimson scarlet, striped with white.

Of *Camellias*, cut blooms were furnished by Mr. Bull, Mr. Wilkie, and Mr. Trussler, gardener to D. J. Kay, Esq., Hoddesdon, who received prizes in the order named, also by Messrs. Lee, of Hammer-smith; and Mr. Wilkie had a first prize for three plants in bloom.

Cyclamens, as already remarked, were of first-rate excellence, especially those from Mr. Wiggins, gardener to W. Beck, Esq., of Isleworth, who gained the first prize, and who likewise exhibited a collection, for which he took an extra prize. One potful, in particular, formed such a dense mass of bloom, that it would have required a very considerable amount of time and patience to have counted the number of flowers. Mr. Fairbairn and Mr. James were respectively second and third.

The miscellaneous class was a most interesting one, being, in fact, a show of itself, and though only three prizes were offered, the Judges having, from a want of competition in two or three of the classes, a small sum at command, were enabled to award several extra prizes; but as the miscellaneous class has of late acquired great interest and importance, it may be questioned whether a larger amount of prizes might not be left to the discretion of the Judges to award in it should no accidental circumstance such as that referred to occur. Mr. Wilkie

took the first prize with a collection of flowering plants, in which were *Azalea*, *Rhododendrons*, *Hoteia japonica*, and *Lily of the Valley*. Mr. Williams, of Holloway, had a second prize for a collection, consisting of *Palms*, *Azaleas*, *Ferns*, *Heaths*, *Clematis*, *Dracænas*, *Yuccas*, and a *Begonia* which roots at the joints, and is of Ivy-like habit. Mr. Kettlewell, of Potter's Bar, also obtained a second prize for a collection, in which were *Azaleas*, *Pelargoniums*, *Hydrangeas*, *Dendrobium nobile*, and double-flowered *Petunias*; and Mr. Ware, Hale Farm Nurseries, Tottenham, was third with a very interesting collection, in which there were many beautiful herbaceous plants. Among them were the white-flowered *Primula Munroi*, *P. cortusoides amona*, *Cyclamen repandum*, deep crimson; a showy mass of the yellow *Hose-in-Hose Primula*, *Polyanthuses*, *Gentiana acaulis*, pretty little *Anbrietias*, both variegated and plain-leaved, various *Forget-me-nots*, *Celsia cretica*, *Faringium grande*, *Funkias*, and the *Ancuba-leaved Daisy*. Messrs. Veitch sent *Anthurium Scherzerianum* in splendid condition; *Clematis John Gould Veitch*, with large lilac blue flowers, in which there are four or five tiers of petals, a very showy free-flowering hardy climber; and *Azalea James Veitch*, with bright crimson flowers. Mr. Bull contributed two well-matched fine plants of *Agave filifera*, *Pandanads*, *Palms*, *Yuccas*, *Ferns*, *Anthurium Scherzerianum*, *Uropodium Lindenii*, and *Lasiandra macrantha*, a *Melastomaceus* plant with purplish violet flowers at least 4 inches in diameter. Messrs. Lee, of Hammersmith, had *Camellias*, a vigorous-growing handsome *Cibotium*, and a magnificent specimen of *Medinilla magnifica*, with upwards of a score of its large and handsome pendulous bright pink panicles. Mr. Watson, St. Albans, and Messrs. F. & A. Smith, of Dulwich, had *Tricolor Pelargoniums*, of which one called Mrs. Gladstone, shown by the former, had very thick leathery foliage; Mr. Marcham, fine-leaved *Begonias*; Mr. Kettlewell, *Pelargoniums* for forcing and market purposes, in excellent bloom; and Mr. Roberts, gardener to Lord Cranworth, Holmwood, Bromley, strong well-grown *Neapolitan Violets* and *Mignonette*. *Clerodendron Bungei* with large leaves, variegated with cream colour, came from M. Jean Verschaffelt, of Ghent, and two seedling *Sikkim Rhododendrons* from Mr. Osman, gardener to R. Holland, Esq., Stanmore.

Mr. Wiggins took an extra prize for an excellent collection of *Polyanthuses*, of which flower Mr. Marcham had also good examples; and Mr. Turner, of Slough, and Mr. James, of Isleworth, received extra prizes for beautiful collections of *Auriculas*, remarkable for their vigour of growth, the size of truss and pip, and the beauty of their colours. It may be useful to name half a dozen of the best in each class as shown by Mr. Turner. These were: *Green edges*—Cheetham's Lancashire Hero (shown as a green edge), Campbell's Admiral Napier, Oliver's Lovely Ann, Traill's General Neill, Litton's Imperator, Dickson's Duke of Cambridge. *Grey edges*—Headley's George Lightbody, Turner's Colonel Champeys, a splendid new variety, Lightbody's Richard Headley, Chapman's Sophia, Read's Miss Giddings, Sir William Wallace. *White edges*—Taylor's Glory, Leigh's Bright Venus, Lightbody's Fair Maid and Countess of Dunmore, Summerscales' Catharina, Ashworth's Regulator. *Selys*—Spalding's Metropolitan, Sims' Vulcan, Turner's Cheerfulness, Lightbody's Meteor Flag, Turner's Crown Prince, and Bishop of Liebfeld. Turner's Canary is also very showy as a yellow. Mr. James had fine examples of several of the above, *Formosa*, *Mayfield*, Turner's *Crown Prince*, *Blackbird*, Mrs. Sturrock, Lancashire Hero, Conqueror of Europe, Ann Smith, Robert Burns, Bright Venus, Lass of Wilton, &c., and his collection both individually and as a whole was most praiseworthy. Mr. Turner also obtained an extra prize for a collection of *Alpine Auriculas*, which, though not esteemed florists' flowers, are nevertheless very ornamental, and are of more easy culture. This class of *Auriculas* he has greatly improved, and in it, chiefly through his exertions, we have now many fine varieties. Such are *Landseer*, deep maroon; *Jessie*, shaded violet; *Princess*; *Tidian*, brownish crimson; *Sir R. Napier*, and *Black Prince*.

The other subjects which it remains for us to notice were *Pansy* blooms from Mr. Bragg, of Slough, and Mr. Hooper, of Batb, from the latter of whom one called *Sunset*, a showy yellow kind, was shown as a "hedder"; and lastly, a cluster of *Musa Cavendishii* weighing 56 lbs., sent by Mr. Sage, gardener to Earl Brownlow at Ashridge.

It may be well here to mention in conclusion, that the period during which Messrs. Lane's Show will continue open has been extended to Saturday next. That it is well worthy of inspection we have already remarked.

FRUIT COMMITTEE, April 21st.—G. F. Wilson, Esq., F.R.S., [in the chair. In vegetables a prize was offered for the best brace of Cucumber. Mr. Earley, gardener to F. Pryor, Esq., Digswell, exhibited *Kenyon's Improved*; Mr. Parsons, gardener to R. Attenborough, Esq., Acton Green, sent *Gunner's Green*; Mr. Cadger, Luton Park, sent *Dale's Conqueror* and *Berkshire Champion*. The first prize was awarded to Mr. Earley's *Kenyon's Improved*, and the second prize to Mr. Cadger's *Dale's Conqueror*. Mr. Cadger also exhibited specimens of *Prince of Wales Kidney Potato*, which, when cooked, was found to possess great excellence, and was highly commended. Mr. William Paul sent samples of *Waltham Market Cabbage*; Mr. Whiting, of The Deepdene, sent samples of *Anderson's Protecting Broccoli*, which were much admired. A very fine collection of thirty-four varieties of *Lettuces* was sent from the Society's garden at Chiswick. Mr. Stevens, of Trentham, sent a very fine dish of *Black Tartarian Cherries*, which

were so meritorious that the Committee unanimously awarded them a special certificate. Mr. Cox, of Redleaf, sent a dish of *Knight's Monarch Pear*, which had been preserved in corkdust. The fruit was in fine condition, and some of the specimens appeared as if they would keep very much longer; and the corkdust did not in the least communicate any flavour to the fruit.

A prize was offered for the best three dishes of dessert Apples. Mr. Cox, of Redleaf, sent *Formosa Pippin*, *Golden Harvey*, *Golden Knob*, and another collection consisting of *Court of Wick*, *Harvey Pippin*, and *Russet Nonpareil*. Mr. Parsons, Acton Green, sent *Golden Reinette*, *Golden Russet*, and *Dutch Mignonne*. Mr. Dixon, gardener to Lady Holland, Holland House, sent *Wyken Pippin*, *Cluster Golden Pippin*, and *Golden Knob*. Mr. Cox's first collection received the first prize. As there was no other collection of sufficient merit, the second prize was not awarded. For kitchen Apples, Mr. Parsons sent *Dumelow's Seedling*, *Alfriston*, and *Northern Greening*. Mr. Dixon sent *French Crab*, *Norfolk Beefing*, and *London Pippin*. Mr. Cox, of Redleaf, sent *Scarlet Winter Pearmain*, *Claude*, and *Dumelow's Seedling*. Mr. Parsons received the first prize, and Mr. Cox the second.

FLORAL COMMITTEE, April 21st.—There were many entries of plants for the examination of the Committee, some of them of considerable interest. The number of certificates granted will prove that there was much to be done; indeed, the great increase of subjects sent to the Tuesday meetings will necessitate punctuality in the attendance of the members of the Committee, and the request this day made by the Council, that business should commence henceforth punctually at eleven o'clock must be strictly observed.

Among the exhibitors, Mr. Roberts sent specimens of *Neapolitan Violets* and *Mignonette*; Mr. Hooper, Bath, cut flowers of *Pansies*; Messrs. Veitch a fine collection of *Orchids* and greenhouse spring-flowering plants, *Clematis John Gould Veitch*, a pale, double, light blue or grey variety, which was awarded a first-class certificate; and a weeping Fern well suited for basket work, with its palmate fronds, *Acrostichum palmatum*—first-class certificate. Messrs. Veitch received a special certificate for their collection of *Orchids*, and one for their collection of greenhouse spring-flowering plants. Among the *Orchids* was a weak specimen of *Nasonia cinnabarina*. Although much is said in praise of this *Orchid*, small and beautiful as it may be, the opinion of its real merits in its present state of cultivation cannot be defined; it must be seen again in better condition to gain a position among its fellows. Messrs. Veitch also sent *Cupressus macrocarpa variegata*, which received a first-class certificate in 1867; *Gesnera macrantha*, of which we shall hear more; *Pteris serrulata variegata*; an *Echeveria*, called *agavoides*; *Agave schidigera*, *Phalenopsis Parishii*, *Angulca uniflora splendens*, exhibited at the previous meeting as a species not then named, and which received a first-class certificate; and *Zygotetium brachypetalum*. Among the beautiful spring-flowering collection, *Azalea Stella* was very conspicuous. It is one of the best varieties in cultivation.

Mr. Williams, Holloway, received first-class certificates for *Cibotium spectabile* and *Cibotium regale*, two magnificent tree Ferns; also for *Asplenium auriculatum*, and *Zamia Ghellinchi*, of which latter the specific name is to be changed. Mr. Williams also had a special certificate for a handsome group of *Amaryllis*. Mr. Bull received a certificate for *Cibotium regale*, also exhibited by Mr. Williams, and a special certificate for his collection of plants. M. Jean Verschaffelt sent plants of *Clerodendron Bungei variegatum*. Some doubt was expressed as to its habit; should it stand the test of being planted out of doors in the summer months, it will prove a great acquisition.

Mr. Parsons, Daneshury, sent *Azalea Magenta Queen*, not equal to *Cedo Nulli*, or *Perfection*, of the same shade of colour. From Messrs. Rollisson, Tooting, came *Juniperus excelsa stricta*, a neat and elegant shrub, perfectly hardy, which received a first-class certificate; also *Rhododendron fragrantissimum*, with beautiful large white flowers stained with rose, and highly scented. To this a first-class certificate was also awarded. *Saccolabium ampallaceum moulineense*, from the same firm, with dark purplish rose flowers, was one of the prettiest specimens yet exhibited, although not new. A special certificate was awarded it.

Mr. Rae, gardener to the Earl of Eglinton, sent a collection of *ent Cinerarias*; plants of *Cinerarias* must be seen to judge of their merits. Messrs. Downie, Laird, & Laing had a small group of *Zonal Pelargoniums* of the *Golden Bronze* section, well grown and very effective. A special certificate was awarded. The same firm received also a special certificate for some fine specimens of *Pansies*. Mr. Wilson, gardener to W. Marshall, Esq., was awarded a first-class certificate for *Oncidium Marshallii*, the finest *Oncidium* yet seen, with large, fine, spreading yellow flowers; a first-class certificate for *Oncidium serratum*, very beautiful; and a second-class certificate for *Oncidium pubes*. A very fine specimen of *Odontoglossum triumphans* was awarded a special certificate.

Mr. William Paul gained a first-class certificate for *Madame la Baronne de Rothschild*, a new Rose, pale silvery pink, a lovely flower, not very double in the present season, but valuable for its shade of colour, and which will, doubtless, improve. Messrs. Smith, of Dulwich, sent a pretty collection of *Variegated Zonal Pelargoniums*, which was awarded a special certificate. Messrs. Paul & Son, Chesham, exhibited a small group of *Fritillarias*, among them a novelty, *F. pallidiflora*; a special certificate was awarded. Plants of this class

are objects of great interest, and the members of the Society would be greatly pleased to have more frequent exhibition of them.

Mr. Sherratt, gardener to J. Bateman, Esq., received a special certificate for some very fine spikes of *Dendrobium Dalhousianum*. Mr. Baxter, gardener to C. Keiser, Esq., Broxbourne, exhibited a cat flower of a *Cattleya* sent out from the Society's gardens four years ago, one of Mr. Weir's introduction, and which was found to be *C. intermedia*. A special certificate was awarded to Mr. Baxter for his collection of *Amaryllids*. A seedling dark crimson variety of fine form, named Rembrandt, was awarded a first-class certificate. Mr. Stone, gardener to J. Day, Esq., Tottenham, received a first-class certificate for *Saccolabium curvifolium luteum*, with deep yellow flowers, and a special for his collection of Orchids.

Mr. Dean, Shipley Nurseries, Bradford, had a first-class certificate for *Lomaria gibba* major, a very fine Fern; Messrs. E. G. Henderson a special certificate for good specimens of *Blandfordia*, also for a nice collection of Orchids. Mr. Green, gardener to W. W. Saunders, Esq., was awarded a special certificate for a very curious and interesting collection of plants. Mr. Stevens, Ealing, sent a double white *Petunia* named Excellent, two variegated *Pelargoniums* out of condition, but very promising, and called Beauty of Ealing and Mrs. Stevens; also a rough-leaved seedling variegated Ivy-leaved *Pelargonium*, too coarse for bedding or any purpose. Mr. Mills, gardener to Dr. Pattison, St. John's Wood, sent a fine specimen of *Oncidium bifolium*, which was awarded a special certificate; and Mr. R. J. Veitch, Exeter, sent specimens of a seedling white *Azalea* not named, and rather rough in outline. Mr. Kieghorn exhibited a small specimen of his striped seedling *Azalea Lizzie*, which well maintains its character and desert of a first-class certificate.

GENERAL MEETING.—W. Wilson Saunders, Esq., F.R.S., in the chair. After a list of donations of plants and seeds had been read, and a vote of thanks accorded to the donors, ten new Fellows were elected, and the South Nottinghamshire Horticultural Society was admitted into union. The awards of the Fruit and Floral Committees having been reported as usual to the Meeting, the Chairman called on the Rev. M. J. Berkeley to make any remarks which he might have to offer.

Mr. Berkeley said that at the last Meeting a magnificent *Gesnera* had been exhibited by Mr. R. Tanton, nurseryman, of Epsom, and which had been sent home by Mr. Tanton's brother. Two members of the Floral Committee thought at the time it was exhibited that it was identical with *Gesnera macrantha purpurea*; and on referring to the "Gardener's Magazine of Botany," published some years ago, he found a very exact representation of the plant, and it was there stated that an unknown *Gesnera* crossed with *Gesnera Cooperi*, which is a form of *Gesnera bulbosa*, gave *Gesnera macrantha*; that *Gesnera macrantha* crossed with another variety gave *Gesnera macrantha purpurea* which agrees perfectly with the natural hybrid. Here then, if the two plants—that naturally and that artificially produced—were identical, we had an important illustration of the Darwinian theory. Mr. Tanton, who some years ago was one of the foremen at Chiswick, remarked in a letter:—"I have for years grown and been very fond of this family, especially the old species. The true *Gesnera macrantha purpurea* has a blackish purple lip, while my imported species has only two small purplish blotches on each side of the lip and partially down the throat. Again, in growing, it is dwarfer in habit, leaves larger and more fleshy, especially the lamina, and has withal a tendency to flower perpetually. The plant I exhibited has been in flower upwards of two months, and to all appearance from the buds which continue to emanate from the axils of the flowers it will bloom two or three months longer. Now, *G. macrantha purpurea* flowers and is gone in a month, and the growth immediately dies away and the bulb goes to rest. The same is the case with *G. bulbosa*, *Cooperi*, &c."

Mr. Tanton had promised to send the plant again, and he (Mr. Berkeley), had requested Messrs. Veitch to send a plant of *G. macrantha purpurea* for comparison, and he hoped others would do the same.

On two or three occasions lately they had had instances of abnormal structure in Orchids. In one case there was a double column, in another a double lip; and in a *Cypripedium* at the last meeting the lip was almost altogether obliterated, whilst at this there was a flower of *Cattleya amethystina* with only three of its divisions developed. Attention was then directed to *Ismene calathina* from Mr. Wilson Saunders, and an extremely interesting *Sarrumatum*, *S. asperum*, from the same gentleman, and which was one of those species which throw up a beautifully variegated stem, this being produced after the flowers. The latter were not remarkable for their beauty, and in some plants of this order are extremely offensive; so much so that one—*Conophallus bulbifer*, was kept outside the room. *Blandfordia flammula* and *Cunninghami* then came under notice; and Mr. Berkeley observed that Sir William Hooker, in describing *B. flammula*, remarked on the extreme variability of the species, saying of *B. Cunninghami*, discovered by Allan Cunningham, "Fine specimens of the plant are in our herbarium, gathered in the Blue Mountains; but so variable were the species of *Blandfordia* considered by that practical botanist Mr. Cunningham, that he has indicated it as '*B. nobilis*: very luxuriant specimens from a stiff and clayey bank, beneath a permanent elevated peaty bog.'" The specimens before the meeting confirmed the remark of Sir W. Hooker.

Mr. Berkeley said he would next call attention to a beautiful Fern, a sport of *Lomaria gibba*, sent by Mr. Dean, of the Shipley Nurseries, and which, if examined, would be found to possess no characteristic of *Lomaria gibba*, but to be a true *Blechnum*; and other instances were quoted of the extreme instability of the genera of Ferns, in some of which as many as three or four so-called genera might be observed, according to the degree of development acquired under the circumstances in which they were growing. With regard to *Gibetium regale* and spectabile which were also shown, he understood from persons who had seen them at Ghent, that they were there quite magnificent, having stems as thick as one's arm. He had lately drawn attention to a case of fasciation in *Primula denticulata*, in which the flower stems had become flattened—in fact, incorporated together, but he had never seen fasciation carried to such an extent as in the *Polyanthus* sent by Mr. Cox, of Redleaf, to the present meeting, and the effect of which was extremely beautiful. A plant sent by Messrs. Veitch under the name of *Echeveria agavoides*, but whose proper specific name was *aloides*, it was stated might prove useful for edgings to beds or borders.

Mr. Berkeley said he had now a subject of some importance to bring before the Society. At a meeting of the Society of Arts on Wednesday last the subject of Fungi as an article of food was under discussion, and it was suggested that the Royal Horticultural Society should offer a prize for collections of edible Fungi. One of these, *Agaricus gambosus*, which was sometimes sold in Covent Garden, would probably come in in a few days, and, therefore, it might not be possible to have that in autumn, still there were many that came in together at that season, and a friend of his had proposed a prize for edible Fungi in September. At the same time it was suggested that those known to be poisonous should also be shown.

Mr. Saunders said, with regard to *Ismene calathina* that it was closely allied to *Pancratium*, and was of easy culture. Coming from the warmer parts of Peru, the bulb, after resting, required to be removed to a warmer place after it began to push. As to *Echeveria aloides*, the plant, he believed, was now seen for the first time in flower in this country. It was closely allied to the second section, and might be useful for the same purposes; but *Echeveria glauca*, he believed, would beat it some day.

Mr. Bateman said that the only drawback to an exhibition of Fungi in September would be so many of the members of the Society being out of town, and suggested that the Fungi should be properly dressed, for some that were otherwise poisonous became wholesome when cooked. With regard to Orchids, there was one pre-eminently splendid—*Oncidium Marshallianum*, which must be admitted to bear away the palm from all yellow *Oncids*. When at Berlin he had seen dried specimens of it in the museum, but the first time he had seen it alive was at one of the Regent's Park shows, and then it had only half the number of flowers, and probably in course of time the number of these would be very largely increased. Referring then to *Saccolabium ampullaceum*, the ordinary pale pink variety was considered very fine, but the power of rose could go no farther than in the fine Moulmein variety shown by Messrs. Rolleston, and which he believed formed part of a small parcel of spotted-leaved varieties, imported by Messrs. Low several years ago. Of *Saccolabium curvifolium*, the ordinary colour was the richest cinnabar, but in the variety shown by Mr. Day it was a fine yellow; but though this variety was interesting as a sport, it was not so beautiful as its original. With regard to *Oncidium serotum*, exhibited by Mr. Marshall, it afforded an example of abnormal structure, two of the petals having become conjoined; but when it first flowered with the Bishop of Winchester some of the flowers were without sepals, others without petals.

Next came the genus *Dendrobium*, and among them was *D. Tattorianum*, named after Lord Egerton, of Tatton, and which was not the most remarkable plant of its family, still its flowers were agreeably fragrant, and would last at least two months in perfection, if the plant was properly grown. Because *D. speciosum* also comes from Australia, and would succeed in a greenhouse temperature, people must not suppose that *D. Tattorianum* would do with the same temperature, for the former came from the south, the latter from the north of that island-continent, and from within a few degrees of the equator. Like Cape bulbs, it wanted a good roasting for half the year, then with plenty of heat and moisture it would send up its beautiful racemes. Messrs. Veitch's new *Dendrobium lasioglossum*, from India, he would for the present merely mention. After noticing some cut blooms of *Dendrobiums* from his own garden, among which were the white variety of *Dendrobium nobile*, sometimes misnamed *D. Wallichianum*, and *D. Dalhousianum*, a species producing noble racemes of buff flowers, which remain long in perfection. Mr. Bateman pointed out the splendid specimen of *Oncidium bifolium*, with a spike 2 feet 4 inches in length, shown by Mr. Mills, gardener to Dr. Pattison, and which, he said, would have astonished Orchid-growers thirty years ago. Of *Odontoglossum luteo-purpureum* a number was shown, and in a cool house it did well to mix with other Orchids; and of *Odontoglossum triumphans*, the specimen from Mr. Marshall was deserving of particular attention.

Mr. Bateman next produced to the Meeting a small specimen of the pretty *Cypripedium concolor*, with two flowers, which he believed to be the normal number the plant produces. The genus *Cypripedium* was remarkable for its different tints, and *C. caudatum*, which produces long string-like appendages, which grow at the rate of

2 inches a-day until they attain 2 feet in length was specially noticed. To those who did not wish to grow a large collection of Orchids, he could recommend this genus, of which there were about twenty species available, and all could be easily grown. One might have eight of these in flower at the present time. A beautiful flower of a Cattleya from Mr. Rucker was then exhibited by Mr. Bateman, but he said that it was only one of many varieties of *C. labiata*, between which, *C. Mossie*, and many so-called species the line could no longer be drawn, and they must therefore be "smashed." As a further instance of the diversity of colours which Cattleyas assume, he exhibited two flowers from plants sent home in the same pot by Mr. Weir, one being white, the other of various colours.

Passing to other subjects, Mr. Bateman said he observed that some *Disas* and *Satyriums* were to be sold at Stevens's, and he would just warn those who might be the purchasers not to treat them like *Disa grandiflora*, which is almost an aquatic, whilst these are totally different, and should be treated like Cape bulbs. He remembered being told by Dr. Lindley that no Orchids were comparable in colour to these *Disas* and *Satyriums*, and that among them were blues, yellows, and many other colours. With regard to the Bateman Challenge Medal for Orchids, he had originally intended to offer it to the most successful exhibitor of these in two consecutive years, and had no idea he should have been called upon for a fresh medal so often, but as Mr. Veitch and Mr. Anderson had each carried it off, he must make a fresh arrangement. At first he thought to handicap these two exhibitors heavily, so as to afford others a chance, but the arrangement which he should adopt would probably be this: Next year before Easter the marks should be for the exhibition of *Odontoglossums*, and after Easter for that of *Cypripediums*; but the competitors must also have gained certificates at the Tuesday Meetings. Another matter which he had to mention was the memorial to the late Mr. Skinner. Last year he had had promises of about £100 for the purpose, but the sum he had received fell very far short of that amount, and to borrow an expression from the mortuary column of the *Times*, "Friends will please to take this intimation." He handed the money over to Mr. Wilson Saunders, and as soon as a sufficient amount was received orders would be given for a neat granite memorial fountain to be erected in the garden of the Society.

Mr. Bateman concluded by observing that at the next meeting on the 5th of May, he intended to call attention to the Lognat, which had been fruited both by himself and at Lord Ragots's, and of which, though the quality of the fruit obtained had been good, the quantity was small.

Mr. Saunders said that with regard to the memorial to the late Mr. Skinner, the money in hand was about £40, and he should be glad to receive any subscriptions not paid to Mr. Bateman.

SALE OF HYBRID COLEUSES.

THE collection of twelve beautiful hybrid Coleuses, raised in the Royal Horticultural Society's garden at Chiswick, by Mr. Bause, was yesterday offered for sale by Mr. J. C. Stevens, at his rooms, King Street, Covent Garden. The large room was crowded by leading nurserymen and amateurs, who took a lively interest in the proceedings. Colonel Scott and several members of the Council were present, and among the company we observed Sir Philip De M. G. Egerton, Bart., and other eminent patrons of horticulture.

The competition was spirited and rapid, and the following is the result, with the names of the fortunate possessors:—

Lot 1.— <i>Coleus Berkeleyi</i>	Messrs. Veitch & Sons.....	40 guineas.
" 2.— <i>C. Marshallii</i>	Mr. Willis	25 "
" 3.— <i>C. Saundersii</i>	Messrs. Veitch & Sons.....	26 pounds.
" 4.— <i>C. Dixii</i>	Messrs. Carter & Co.....	49 "
" 5.— <i>C. Ruckeri</i>	Messrs. Veitch & Sons.....	40 guineas.
" 6.— <i>C. Murrayi</i>	Mr. Willis	25 "
" 7.— <i>C. Bausei</i>	Messrs. Veitch & Sons.....	50 "
" 8.— <i>C. Gotti</i>	"	36 "
" 9.— <i>C. Clerkii</i>	Messrs. Carter & Co.....	40 "
" 10.— <i>C. Batemanii</i>	Messrs. Veitch & Sons.....	49 "
" 11.— <i>C. Wilsoni</i>	Messrs. Carter & Co.....	14 "
" 12.— <i>C. Reevesii</i>	"	5 "

The total sale, therefore amounts to the sum of £393 3s., and we congratulate the fortunate purchasers on having become possessed of those charming plants.

Not the least gratifying feature in connection with this sale is that the whole of the amount realised will be retained as a separate fund, and appropriated to the development of further experiments at Chiswick garden.

THE SCIENTIFIC COMMITTEE OF THE ROYAL HORTICULTURAL SOCIETY.

THE first meeting of the Scientific Committee of the Royal Horticultural Society was held on Monday last the 20th inst., W. Wilson Saunders, Esq., F.R.S., in the chair. As this was merely an inaugural meeting, the main business transacted was the constitution of the Committee, and the consideration

of the modes in which its ultimate working will be conducted. The Committee as it at present exists is constituted as follows: *Chairman*.—The Duke of Buccleuch, K.G. *Vice-Chairmen*.—*Warren De la Rue, Ph.D., F.R.S.; *W. Wilson Saunders, F.R.S.; *Thomas Thomson, M.D., F.R.S. *Secretary*.—*Rev. M. J. Berkeley. *Members*.—*Abel, Frederick Augustus, F.R.S.; Baker, J. G.; Bateman, James, F.R.S.; Bentham, George, F.R.S., P.L.S.; Bentley, Professor Robert, F.L.S.; Blenkins, George E.; *Clarke, Major Trevor; Darwin, Charles, M.A., F.R.S.; Dix, Rev. Joshua; *Fortune, Robert; Frankland, Professor Edward; Gibbs, E. T. Brandreth; *Gilbert, Dr. J. H.; Glaisher, James, F.R.S.; Henry, J. Anderson, F.L.S.; *Hogg, Robert, LL.D., F.L.S.; Hooker, Dr. Joseph, F.R.S.; Howard, J. E., F.L.S.; Johnson, George William; *Marshall, William; *Masters, Maxwell T., M.D., F.L.S.; Miers, John, F.R.S.; Munby, Giles; *Murray, Andrew, F.L.S.; *Moore, Thomas, F.L.S.; Reeves, J. Russell, F.R.S.; Rucker, Sigismund, F.L.S.; *Scott, Lieut.-Col., R.E., F.L.S.; Spencer, Herbert; *Voelcker, Dr.; *Wilson, George F., F.R.S.; *Welwitsch, F., M.D., F.L.S. Of these, those marked with an asterisk were present at the meeting.

It was proposed that as insects and the study of their habits and economy have very important bearings on the culture, reproduction, and diseases of plants, the following eminent entomologists should be invited to join the Committee—Professor Westwood, F.L.S., Sir John Lubbock, Bart., F.R.S., and H. T. Stainton, Esq., F.L.S. The Rev. M. J. Berkeley, the Secretary, then read the following address:—

"As this is the first meeting of the Scientific Committee of the Horticultural Society, it seems advisable that the Secretary should offer some observations on its objects, and the best means of carrying them out effectually. It is above all things necessary that we should perfectly understand the position in which we are placed as a Committee, and the more especially as its members are not necessarily Fellows of the Society.

"The Society, it must be remembered, is not exactly in the same position as most other learned societies, with the exception perhaps of the Zoological Society. Though the income is large, it is not simply available, as in other scientific bodies, for purely scientific objects. The funds applicable to publication are necessarily limited, and it is to this cause especially that the discontinuance of the first series of the Journal, and the occasional appearance of the new series, are attributable, and not to any lukewarmness or narrowness of views on the part of the Society. If the history of the learned societies were to be accurately traced, we should find that the appearance of their transactions has for the most part been irregular, and in consequence, the publication of important papers has frequently been seriously delayed, and for this, amongst other reasons, the 'Comptes Rendus' of the meetings of the French Institute was projected, to enable authors of valuable memoirs to register their discoveries, or in other words 'pour prendre date.' It must not therefore be assumed that our Journal can be published oftener than once or twice a year, or under the most favourable circumstances more frequently than once a quarter, but as reports will undoubtedly appear in our leading horticultural papers, no unwillingness on the part of authors to present memoirs at our meetings need on this score be anticipated.

"The object of our meetings, as stated in the number of the Proceedings just published, is to promote and encourage the application of physiology and botany to purposes of practical culture, whether of plants, or trees, or shrubs, and to originate experiments which may assist in the elucidation of such questions. The terms, it is clear, are sufficiently large to include everything which can come within the scope of a Botanical Committee, and are by no means to be confined to what may strictly be termed physiology or biology. Morphology as well as vital action will occasionally come before us, questions of correct nomenclature, information of general horticultural or more purely botanical interest, botanical geography—in short, everything which does not fairly come within the compass of the Floral or Fruit Committees. The several horticultural directors will naturally bring before us any matter of interest which may occur in the fruit or floral departments, or which may suggest itself at Chiswick, such as have usually been laid before the Society at its Tuesday meetings, doubtful plants will be presented to us for determination, subjects which require elucidation will be mooted, and occasional papers read in accordance with the especial objects of the Committee. Not only is it hoped that individual members of the Committee will help us, but the co-operation of the Fellows of the Society in general, and indeed of men of science, whether members or not, is earnestly invited.

"As regards purely physiological matters it is highly necessary that we should set out with a distinct understanding. It is easy to suggest experiments, but we must at the same time appreciate the difficulties which attend them. Any expectation that the Society itself can at once enter upon a large series of delicate experiments would only meet with disappointment. We ourselves cannot fail to appreciate at once the difficulties of the subject, but it is necessary also that the members of the Society, and the horticultural world in general, should equally realise the true state of the case. The successful conduct of

purely physiological experiments requires an innate love of the necessary research, unwearied labour in the pursuit, uninterrupted leisure, and a rare combination of tact and talent; patient of failure, yet confident of ultimate success; at once free from prejudice, and ardent in the pursuit of the especial object of research. It must be a labour of love or it will lead to nothing. The Society trusts that the establishment of this Committee may inspire some of its members with the requisite zeal; but it must at once be clearly understood that it would be impossible for it as a preliminary step to organise a staff purely for such a purpose. It would be almost hopeless at the present moment to find a person competent for the leader of such a staff, even at a large salary; several assistants would be requisite, perfect instruments and a chemical laboratory, while the person who might be great in one direction would be almost useless in another. Such investigations must to a great extent be carried out in the first instance at least, by private individuals, but the Society would not be backward in giving pecuniary assistance where there was a reasonable prospect of important results. Minor experiments would indeed immediately come within the scope of the Society, as the reciprocal influence of stock and graft, the modifications produced by different stocks, varieties in the mode of culture, the influence of different kinds of manure, and indeed a host of other matters meteorological, physiological, and practical, which may tend to the promotion of scientific horticulture.

There is also another direction in which the Committee might be extremely useful, and which would at once be acceptable to all our members, and to all lovers of horticulture. It is frequently a complaint that plants in collections are so badly named, and that the correct appreciation of what may be called their botanical attributes, in contradistinction to those which are simply floricultural, is at present so very imperfect. This arises in great measure from the want of useful manuals, from which the necessary information can be obtained. When the number of plants under cultivation was comparatively small, the '*Hortus Kewensis*' was available for the more scientific gardeners, but though there are some praiseworthy exceptions, such as London's, the cultivator is for the most part compelled to pore over mere catalogues, which can give him only an empirical knowledge, while as frequently he will fall into error. It is believed that the publication of a series of manuals, judiciously selected, would be highly calculated to promote a general love of scientific botany where there is at present mere floricultural knowledge, and the more so as the desire of mere display seems on the wane, while an appreciation of elegance of form and foliage, and delicacy and variety of structure is daily increasing. Each volume might be complete in itself, while if the plan were well carried out a series of publications would be produced, highly honourable to the Society and of great importance to horticulture. The suggestion I would observe originated with a member of our Committee, who has the power and the will at once to aid in the realisation of such a scheme, and when I mention Dr. Hooker as its originator, it will assuredly be evident how materially it might be promoted by the staff at the Herbarium and the superintendents of the different departments in the gardens at Kew. Suppose, for instance, we were to undertake a volume on Conifers, for which Gordon's manual is now quite insufficient, another on Herbaceous plants more usually cultivated, another on rock and Alpine plants, or to descend to especial genera, one illustrating *Dendrobium*, *Epidendrum*, and *Oncidium*. What a boon would such volumes be to our members. The scheme, moreover, with the aid which has been promised might be carried out at a comparatively small expense, and with a degree of speed and correctness which would be quite out of the power of any individual.

The Committee will of course be prepared to receive suggestions as to any other plans or modes of action which may be thought advisable, but it is absolutely necessary that such suggestions should be submitted in writing, that the terms may be distinctly understood. Their ultimate adoption will of course rest with the Council."

It was arranged that the meetings of the Committee will be held on the same days as the two other Committees meet, at half-past one o'clock. As this will necessitate greater punctuality on the part of the Fruit and Floral Committees, they will in future commence their work at eleven o'clock precisely, before which exhibitors should secure that their subjects are forward in time. It was also decided that the chemists should form a sub-committee, of which Dr. Warren De la Rue is to be Chairman, and Dr. Voelcker Secretary.

From the spirited conversation which pervaded the meeting, and the manifest interest which every member present appeared to take in the proceedings and in its future success, there can be no doubt that the step which has been taken by the Council in instituting the Committee has been a proper one; and composed as it is of men of the highest eminence in the departments of science to which they belong, there can be but one opinion—that if good is to result to horticulture by such an association, we have here the right material for securing it.

STANDARD ROSES ON LIGHT SOIL.

In each of the last three autumns I have planted about a dozen standard Roses, but none of them will thrive, and each

spring two or three of them die. This spring three, planted prior to last autumn, which looked well, and began to break nicely and come into leaf, have within the last week or ten days begun to wither, and look as if they would follow the example of those which have gone before them. Several cuttings, also, which looked well all through the winter, are now dying off. The soil is light and sandy over a gravelly subsoil, which I have enriched with stable manure. All the trees and cuttings were mulched with long litter during the winter.—W. M.

[Except in strong, unctuous, clay lands, I am an enemy to standard Roses, save of Tea-scented Noisettes and summer Roses, which do well on Briars in any land, however light, if properly attended to.]

The fault, however, is not always in the Briar or the Rose on it. The fact is, amateurs as yet know little about Rose-growing, or they have no time or inclination to grow Roses properly. I imagine "W. M.'s" Roses are simply frosted in their foliage, and that the withering of the leaves proceeds from that cause only. The cuttings that looked well all winter and are now dying off have probably made no root at all. If they have made roots and are not dead they will soon recover. I advise "W. M." to buy Roses on the Manetti stock and on their own roots. His ground is better suited to them. If purchased on the Manetti stock and properly planted, they will soon strike in such ground on their own roots.—W. F. RADCLIFFE.]

INDIAN MODE OF LAYERING.

The following are representations of the mode of separating a bearing branch of a fruit tree as practised in Bengal by the native gardeners, also in China.

The branch thus separated is planted in its proper place, and bears its fruit the same year, just as if it had remained upon the parent tree.

Fig. 1.

In fig. 1 *a* is an enlarged drawing of part of the branch; *b* is an earthen pot to hold water, which in the dry season of the year is daily supplied. There is a small hole in the bottom of the pot, in which a piece of string or straw is put, so as to conduct the water by drops to *c*. *c* is a ball of clay put round the branch at the place above that at which the branch is to be cut off. Round the clay is wrapped a piece of coarse sacking or sail cloth, which absorbs the water as it drops from the pot *b*, and keeps the clay continually moist. At *d*, just below the ball of clay, the bark of the branch to be separated is cut off and peeled down to the woody substance only as much as half round the branch, and about an inch in breadth. After a month or six weeks small fibres of roots will begin to appear through the clay (*c*, fig. 2), when the circle of bark must be

Fig. 2.

completed by cutting round the branch, and forming a complete ring, *f*, free from any bark. The fibres of the roots will

soon increase, and be observed to penetrate the coarse sackcloth and appear outside, and when these are sufficiently vigorous the branch may be cut off and planted.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Asparagus, in cutting this for use see that the weak spindling shoots are cut off at the same time, that they may not hinder the better from coming regularly forward. *Broccoli*, seed should now be sown for the main supply next winter and spring. The Dwarf and Tall Sprouting are the most economical and useful of all the Cabbage tribe for winter Greens; if these are sown now, and again at the beginning of May, they will produce tender sprouts from November till this time next year. No cottage garden should be without these varieties, which are far preferable to *Borecole*. *Kidney Beans*, plant in boxes to be protected for a time, and in the open ground to take their chance of the season. *Peas and Beans*, together with *Spinach*, *Turnips*, *Salads*, and other succession crops, must now be sown oftener, and in smaller quantities till midsummer, as they will come in faster during hot weather. *Sea-kale*, clear away the litter and pots as the stools get past use. Cut over the shoots level with the ground, and dig over the beds, and if the stools throw up more shoots than can be fully exposed to the sun and air thin them out.

FRUIT GARDEN.

Plum and Pear trees will now be ready to have some of the strongest young shoots stopped. The Apricot, Plum, and Cherry must be carefully looked over to find the mischievous little caterpillar which shuts itself up by twisting the young foliage round its retreat. This caterpillar never occurs in great numbers, and is easily kept under. Now is an anxious time with the gardener while the host of winged insects, caterpillars, slugs, and worms are busy at their work of destruction, and perpetual war must be maintained against them, to say nothing of the care and judgment necessary in regulating the young shoots on wall and espalier trees.

FLOWER GARDEN.

Some of the early-sown annuals will now require thinning out, in doing which remove all but five or six of the strongest plants, and these, if not very strong, may have the terminal leaf buds removed to make them bushy. Stir the ground round the plants deeply with the hoe, and if they are weakly apply a slight dressing of guano, and then give a good soaking of water. Many of the herbaceous plants will now require a little thinning and training, and in regulating them do not bundle them up like so many pea sticks, but tie the branches out separately as you would a prize *Pelargonium*. Attend to the young growths of climbers before they become crowded, and remove any stray branches which are not likely to produce flowers. The covering from half-hardy plants may now be removed entirely in the daytime; but it will be well for a fortnight longer to stretch a mat over the tops of the plants for fear of frost. Keep all newly-planted trees well watered, and recently-laid turf should be watered and afterwards covered with old tan to prevent its burning. Examine *Roses* to see that the bud-worm is not at work, and dress them, if necessary, with tobacco water and soap-suds to clear them of the green fly. Many of the strong-growing hybrid China and French varieties will be the better of having some of the strong growths thinned out—indeed, no more branches should be left upon a *Rose* than can be properly exposed to the sun and air. Remove the strongest branches, which frequently run into gross shoots; the middle-sized ones generally produce the finest flowers. Auricles are in most situations fully expanded, with the exception of the northern counties, where they are somewhat later. In order to preserve the bloom the pots must be removed to a cold place, having a north aspect. The direct rays of the sun have a prejudicial effect on the colours, causing the dark or body colour to start or diffuse itself over the margin. Few spring flowers are so beautiful or more worthy of the trouble requisite to insure their perfection. This dry weather is trying to *Polyanthuses*, and is favourable to the attacks of red spider. This pest dislikes moisture. Should a plant be affected (which is soon ascertained by the margin of the leaves turning inwards and assuming a yellow hue), it is found that by watering it well and placing a common garden pot over it, occasionally discharging some Scotch snuff on the under sides of the leaves, the insect may be destroyed. The sticks had better be inserted in the blooming pots of Car-

nations, *Picotees*, and *Pinks*, to support some varieties that have a tendency to spindle early, and if delayed longer pushing the sticks down is apt to injure the roots. Keep the pots free from weeds.

GREENHOUSE AND CONSERVATORY.

Camellias now making their growth require larger portions of water daily if the pots are thoroughly drained. Orange trees also require more water for the next month than at any other time. Some of the *Passion-flowers*, *Ipomæas*, and other strong-growing climbers should now be close-pruned if you wish for a late display in autumn. In former years it was a prevalent opinion that *Heaths*, *Epacris*, and similar plants would be ruined if touched with a knife, but now it is proved that no plant bears pruning better, and men in nurseries may be seen cutting off the young tops of these in handfuls after the plants have done flowering. Other free-growing plants have their tops regularly pinched off at every other joint, in order to form them into round bushy specimens. Let the greenhouse be syringed every afternoon, and the house shut up at night till the growth of the principal tribes is nearly finished, when they may be kept more cool and dry to ripen them off slowly.

STOVE.

The plants in general promise to make a healthy and early growth this season, owing to the summer-like weather we have been favoured with; stimulants may, therefore, be applied earlier than usual to such strong-growing plants as are known to be so benefited. Stove plants at this stage and under strong sun can hardly be kept too hot in the daytime, provided a slight shade is thrown over the glass, the atmosphere being kept moist, and a free supply of air admitted, and under such treatment they can hardly be too cool at night. Young plants of which it is desired to form fine specimens should be watched, and as soon as their roots have reached the sides of the pots they must be fresh potted. Others, again, must be cramped at the roots to induce them to make short flowering spurs. Many of the climbing plants so treated may be made to assume the character of shrubs, to suit particular circumstances and situations.

PITS AND FRAMES.

Propagation by cuttings and grafts must be continued till a full stock is reared; tender annual seeds for late flowering may now be sown. Very many plants that are difficult to strike from cuttings may be easily increased by grafting on the roots of some allied species. All tender seedlings should be potted as soon as they can be handled. The plants are, of course, being removed from these structures to temporary protections as fast as possible. If they are not quite clean give them a good fumigating before they are taken out. Pot-off all recently-propagated plants, and see that you have a sufficient stock of everything to plant your beds properly; if not, put in some more cuttings without delay, and they will do admirably to fill up gaps in the summer.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

EVERYTHING out of doors was assuming a rather parched appearance, owing to the dry north and easterly winds. The shower of Friday evening, with the wind inclining more to the south, though often going back to the old quarter, made everything look quite different.

Peas planted-out, that were not so green as we like to see them, had the slightest dusting of soot thrown over them, and were then sprinkled from the rose of a watering pot, to enable them to receive better help from the anticipated shower; for we do not expect a very heavy rainfall just yet, and except in particular cases, several times referred to, we do not like sprinkling overhead in bright sunny weather. *Onions*, too, are now coming up vigorously. Some of our very forward neighbours have had to sow again; the keen frost was too much for the young *Onions*, and made them hang their heads, and most of them would never do good afterwards.

Lettuces coming on were hoed, to let air and moisture among them, and many that had been protected were planted out in rows; spring-sown ones out of doors have had the litter and branches removed that kept them from the birds, and it is amazing what a change a single day has made in their appearance.

Parsley.—Main crops were sown in rows, and that for use

nically hood, and plain specimens removed, in case it should be desirable to save a little for seed; but except when the sort is very fine indeed, it is hardly worth while to have the rubbishy appearance of seed beds of Parsley, when seed for a large establishment can be obtained for something like *Gd.* A few weeks ago we removed the row of Parsley from the front of the orchard house, as we wanted the place for setting two rows of Strawberry pots where they would come in a few weeks before plants in the open ground.

Removed the lights from the first-pricked-out *Celery*, and it is growing very freely and strongly with the help of a few large laurel branches laid across it, and these will be thinned gradually before being finally removed some time before the plants are taken to the trenches. Pricked out more *Celery* and young Cauliflowers, to be protected in the same way at first with evergreen boughs, and sowed *Celery* for the last crops. Even with early sowings we rarely have a run head.

In sowing Scarlet Runners, Peas, &c., the other day, in order to keep the seeds from depredators when below ground, to a certain extent, we dusted them over with red lead. Provided such large seeds are just damped previously, a little of the powdered lead, as much as one could hold on the blade of a knife, will colour a quart of such seeds sufficiently, and we have not perceived that it affects their germination at all injuriously.

Potatoes under the protection of old sashes could not be so freely exposed as we would have wished, on account of the north winds, but as soon as the weather became a little milder, we exposed them thoroughly all day, as such exposure causes them to keep more stubby, and to swell their tubers faster than when kept closer. Few of those in the borders are as yet making their appearance, but some forward at the foot of walls have been kept safe by just sprinkling a little dry litter over them, and sticking a few evergreen twigs in front of them. This work is quickly done, and the yield is always better if the top of the Potato is never injured by frost.

Cucumbers in Frames.—These have competed well, as lately stated, with those in a hot-water pit, bearing profusely; and from the time the plants were turned out in the bed, made in the rough-and-ready but safe mode lately adverted to, the frame has given no trouble except air-giving and watering. The only thing done was to lift the frame by placing a brick on the flat beneath each corner, as some of the leaves were touching the glass, and that might have injured them. The heat is still as steady and genial as when the bed was made, and the plants turned out. We would unhesitatingly recommend the plan detailed some time ago, to all amateurs who wish to make the most of their little fermenting material, and to save all trouble afterwards with earthing up their plants or bed.

Sowed a few Cucumber seeds for succession, and others for ridges and pickling, Vegetable Marrows, Tomatoes, &c., preferring to sow thus late to earlier, as the plants will do all the better if they never receive much of a check before being planted out. A small healthy plant will do better than a larger one that has been stunted and starved. Avoiding checks is one of the main elements of success.

FRUIT GARDEN.

What is said above about Cucumbers reminds us of some inquiries as to *Melons* treated in the same way. As previously stated, our frames are shallow, from 15 to 18 inches high at back, and from 9 to 12 inches deep in front. For either Cucumbers or Melons, it follows that the soil can only be a couple of inches higher than the bottom of the frame at back, and not quite so high as the bottom of the frame in front. As already stated, our soil is confined to a trench in the middle of the frame lengthwise, a sprinkling of soil being merely placed back and front to make it all alike in appearance. The frame for the Melons has needed no lifting, as the footstalks of the large leaves are not so long as those of Cucumbers. The soil in the centre gives quite sufficient depth to ripen a heavy crop, and as in the case of the Cucumbers, that soil will be kept moderately warm, whilst the depth of the trench will prevent all danger of burning at the roots. These plants are as yet as robust, free-setting, and free-swelling as could be desired, and have needed no attention but the routine of air-giving, watering, disbudding, stopping, and setting. Here, however, "BEGINNER" tells us these little matters are just those that perplex him. Another correspondent tells us he has tried for years, and has plenty of insects, has plenty of labour, and numbers of small straggling shoots, and just a fruit worth looking at now and then; and "C." would have his cares lessened if helped to

decide whether he should plant only one plant in a light 6 feet by 4 feet, or more plants, as he manages fairly with one Cucumber in a light.

Beginning with the last, we would say that there need be no great care taken by an accomplished Melon-grower, whether he uses one plant or three plants to a light, but to all young beginners we would rather recommend three plants to a light, on the simple principle that in fruiting a Cucumber is very different from a Melon, inasmuch as you may easily have on the former fruit in all stages from blooming to being fit for table, and all the successions growing as well as you can wish them to do; but on a Melon plant whenever one or two Melons begin to swell freely, it is vain to hope that the numbers in a blooming state will ever advance much beyond it until the first fruits ripen. When one plant, therefore, covers a large space, it requires more skill and attention to have the requisite number of fruit set and beginning to swell at one and the same time. Hence, knowing this, when we have allowed a plant to occupy a large space, we have not unfrequently removed a promising fruit or two, because they were so much in advance of the rest, and would have prevented the rest making any progress. It is much easier to have two or four fruit started with equal strength on a plant, than six or a dozen. Hence, for the inexperienced, we recommend two or three plants to a light instead of one.

Like our second correspondent, we have not seldom had a number of shoots and small leaves when we could not overtake our work, or other causes prevented us treating the Melons in, after all, the easiest mode, and that which does them least injury. The mass of shoots is always present when the main runners are stopped prematurely, or there is the necessity for much pruning, which the Melon dislikes. Some time ago our coadjutor, Mr. Abbey, stated that we were the first to unfold a clear simple system of Melon culture, and which without any egotism we mention here, that beginners may see that there may be something in the simple plan recommended. The system is based on the facts that the Melon dislikes much lopping and cutting, that as many large healthy green leaves as can be exposed fully to light do more to insure good Melons than masses of smaller foliage, that the fruit sets best and swells best when there is strength in the plant to carry on the swelling before the fruit appears; and, finally, because, though with exceptions, still it is a general rule that Melons show fruitful flowers most freely on what may be called their tertiary shoots. Thus, supposing we call the stem that rises from the seed the primary shoot, the laterals that would come from the axils of the leaves would be the secondary shoots, and those that come again from the secondary shoots would be the tertiary or fruiting shoots. We will now meet the case of our second correspondent by shortly attending to the wishes of "BEGINNER."

To be as simple as possible, we advise potting the young Melon plants separately, say in 4 or 5-inch pots. As soon as the young shoot has grown two or three joints above the seed leaves nip out its point with the point of a knife. Merely for simplicity, we will suppose that you are to plant out three plants equidistant from each other, and that you are only to take two leaders or secondary shoots from each plant. From your topped plant then, as soon as you discover the best two little shoots coming from the stem, nip out cleanly all embryo shoots except these two; and as they grow train one shoot to the back and one to the front, and the more equal these shoots are in strength the better. As these shoots grow you will find that a third shoot will be coming from the axil of each leaf. Do not permit one of these to grow, but nip them out clean with the point of a knife, so as to make as little wound as possible, and continue this process until these secondary shoots are disbudded of tertiaries for 20 inches or so in length. All this time you have allowed the point of your leading secondary shoot to go on unstoppered; but as soon as beyond the disbudded part you can see from three to five joints, though close together, then nip off the point of the shoot, and that will cause the tertiary shoots to come strongly from the joints not disbudded, and most of these will show fruit at the first joint, and then be stopped at the joint above it. Sometimes the fruit will not show until the second joint, and sometimes not then, and in that case stopping must be resorted to all the same to prevent confusion; but in most cases the fruit will show at the first joint of the tertiary shoot; and there need be no difficulty in setting from two to four Melons on each plant according to size, and which when they swell freely will soon occupy all the energies of the plant. The setting and swelling are so much more cer-

tain, from the strength in the plant before the fruit is allowed to appear; and the disbudding, done more quickly than we can write a line, does away with a spray of useless shoots and the necessity of using the knife among them to give the large primary leaves justice.

In all crops, and especially early ones, it is desirable to assist the setting of the fruit by bringing the male and female flowers into contact with each other, and this is best done in sunshine. During the setting process the atmosphere of the place should be rather dry and airy, and this can hardly be the case unless the soil is dry on the surface. Unlike Cucumbers, Melons rather prefer never to have water poured over their foliage; if even the syringe is used, the moisture should be dissipated and the foliage dry before the sun beats on it strongly. The plants may be watered as wanted at the roots; but when, according to the above plan, we stop the point of the secondary shoots to encourage the free protrusion of the fruitful tertiary, it is well to give as much watering as will save watering again until the fruit be fairly set. If obliged to give it in an extreme case, it is well to supply it to the soil underneath without wetting the surface.

The only other peculiarity is to secure dryness on the surface of the soil as the fruit approaches maturity; but here, too, again by means of holes or drain-tiles set upright, you may give water beneath when you judge there is a need for moisture. This is often required when Melons are grown over hot-water pipes, or tanks, but of that we are not treating, but merely giving the simplest plan for a beginner trying his success over a rough dung bed. There need be no difficulty in effecting a creditable result, if a few minutes can be spared every day to look to the disbudding and stopping, especially before the fruit takes all the running.—R. F.

COVENT GARDEN MARKET.—APRIL 22.

The market is well attended, and there are large supplies, some articles continuing in excess, especially Cucumbers and Kidney Beans. Good samples of the former may be had for 12s. per dozen. The latter bring only a nominal price, those of out-door growth from France competing. Some good parcels of Green Peas are to hand and sell for 5s. per pint ready shelled.

FRUIT.

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

BOOKS (S. A. W.).—Lindley's "Theory of Horticulture" is 21s., and obtainable from any bookseller. Johnson's "Science and Practice of Gardening" is 3s., and may be had free by post from our office if you enclose forty postage stamps.

MOVING MACHINE (S.).—We cannot recommend one more than another, for they all will work well if properly managed. The charge you incurred for repairing was certainly very large, but would have been avoided if you had written to the makers and stated what you required. The cost of carriage to any distance is heavy.

YOUNG GARDENERS AT CHISWICK (W. R.).—If you write to Mr. Barron, Royal Horticultural Society's Garden, Chiswick, he will give you the information you require.

SOIL MANURED WITH SALT (D. S. K.).—Having destroyed the slugs by the application of salt as you state, if the ground be then dug the seed or plants may be inserted immediately.

DRYING FLOWERS (Maude).—Very few retain their full colour when dried. To enable them to retain as much as possible, let them be placed between folds of blotting paper, pressed very gently, and the blotting paper changed for fresh every morning and evening.

RIBES SANGUINEUM (Bruno).—The flowers you enclosed are of far darker crimson than those of the species usually grown. We think it worth propagating, although it may be the sub-variety known as Ribes sanguineum atro-rubrum.

BLIGHT ON HONEYSUCKLES (Viator).—The best thing you could do with your Honeysuckles would be to dust the parts insect-infested with ground tobacco, placing it in a small pepper box, such as may be had of any ironmonger for a penny, having previously given the plant a thorough wetting with water, by which the sun-like ground tobacco will adhere to the shoots. This should be done on a calm evening, and the following evening a good syringing may be given with a solution of soft soap, 2 ozs. to a gallon of rain water. The oftener a plant is syringed in the evening with clear water the less likelihood there will be of insect attacks. It should be done in the evening. Keep the roots well watered and mulched.

CANTUA BUXIFOLIA (W. D. A.).—The sprig sent us is, we think, Cantua buxifolia. It is necessary that it have a position near the glass in a cool airy greenhouse, and be kept rather dry in winter, for it succeeds under the same treatment as Heath. The soil should be open and well drained. If encouraged with heat and moisture it grows too quickly, weak, and tall. No plant succeeds when it is starved. It needs encouragement in the shape of an abundance of air, light, and room.

VERONICA ANDERSONI VARIEGATA FOR BEDDING (A Subscriber).—It succeeds out of doors as a bedding plant, the cuttings being struck in early autumn, potted-off, and wintered in a house from which frost is excluded, keeping the shoots well pinched-back up to May, so as to have a dwarf, compact, bushy plant by planting-out time.

THOMSON'S STYPTIC FOR CUTTINGS (Idem).—By giving a touch of Thomson's styptic to the base of cuttings after they are prepared for insertion, their rooting is facilitated, especially in the case of softwooded plants likely to imbibe moisture considerably, as Pelargoniums, &c. The great art of striking cuttings is to take the growing points, cutting them transversely immediately below a joint, to afford them a slight increase of temperature to that employed for the old plant, to keep the soil uniformly moist, and the atmosphere close, moist, and the cuttings shaded from strong light; but the treatment varies considerably with the subject, so that no definite answer can be given to your query.

SEEDLING ANEMONES (A Constant Reader).—You should mark the best of the plants now they are in flower, and when the foliage fades take them up and replant in a bed by themselves. The others may be planted in any borders where you can find room for them. Do not allow another season to pass without taking up the plants, and affording them more room. You have in a bed of Anemones a charm which few in these days care to possess. Nothing is finer in its season, and it is a pity they are not more extensively cultivated.

IPOMEEA BEDDEREFOIA (A. C. M.).—This, the German Ivy plant, is a very good plant for the purpose you name—viz., that of a background for a tender basket, and all grounds where a speedy evergreen-growth is required. It very much resembles the small green-leaved Ivies, and has pale lilac flowers similar to a Convolvulus. Being of quick growth, and attaining a height of 10 feet, it soon spreads over much space, and should be frequently pinched to have it compact. The plant flowered in the Pine-Apple Place Nursery, Edgware Road, London, in 1859, against a south wall. It is but little known, but deserves to be more cultivated, as it will grow in almost any place where there is slight heat or safety from frost.

GRAFTING THE MALE ON THE FEMALE AUCUBA (E. B. Ryde).—Not having any experience in the grafting of Aucubas, we are unable to say whether it would be practicable to graft the male on the female Aucuba; but we think it likely. Your best mode of proceeding would be by inarching, now being a good time. The graft succeeding and flowering, it would impregnate the flowers of the female plant; but it would answer quite as well to place a male plant by the female as to graft them together, and the flowers can be easily fertilised artificially.

CHERRY TREE INFESTED WITH CATERPILLARS (Ignorant).—The best remedy is hand-picking; but the trees may have white hellebore powder dusted over them with a dredger, which will clear them; and a good syringing or two of a solution of soft soap, 2 ozs. to a gallon of water, will render the trees obnoxious to them. Sparrows have not in our experience interfered with the bloom buds of Gooseberry bushes, but they may occasionally do so, though it has not occurred to us. We have before heard it said they do, and in one such instance we found the bushes of a neighbour had been nearly stripped of their buds by a pair of bullfinches, which we saw on a neighbouring tree awaiting our absence to resume work. The mischief was attributed to the sparrows, but we believe them innocent; indeed, a pair of bullfinches will do more havoc in the way of stripping trees of their buds in a day than we have seen done by sparrows in twenty years. We never saw a chaffinch, or "spink," as you call it, peck at the bud of a fruit tree. We know of many things for poisoning birds, but we shall be of the last to recommend so suicidal a course to the gardener or farmer. We have not forgotten the fable of the farmer and the crow.

TACSONIA VAN-VOLKXEMI (An Inquirer).—We do not know a Passiflora Van-Volkxemi, and we think the plant you have received is Tacsonia Van-Volkxemi, which requires a greenhouse. It will not thrive if planted out of doors. Being a climber it should have a light and airy situation, and be trained near the glass. When growing water it freely, and in winter keep it dry.

PEAR BLOSSOM INJURED BY INSECTS (F. H.).—The specimen enclosed to us has been destroyed by some caterpillar, probably the red-bud caterpillar (Pyrallis luseana), which does considerable injury by preying on the buds. Dusting the trees when the caterpillar makes its appearance with fresh slaked lime is the only remedy.

MARIE LOUISE PEAR LEAVES AND BLOSSOM WRINKLED (A Pear Boy).—Your specimen has the appearance of being affected by the Pear-tree blight—a consequence of the sun's rays being hot and the nights cold.

The only remedy is to protect from frost at night, and shade the trees for a few hours during the day when the sun's rays are very bright and hot. A good syringing would do good.

FLOWER BED PLANTING (F. L.).—Your first mode of planting the bed we do not think would look well. We would have a centre of Coleus or Perilla, and fill the space all round with Lobelia to within 1 foot of the margin, and there have an edging of Cerastium, and in the midst of the Lobelia we would put out 18 inches apart good plants of Mrs. Pollock Pelargonium. The second proposed planting we do not approve of, as Lobelia has a poor appearance next grass, and we should, were this plan adopted, plant Variegated Alyssum along with the Lobelia, having a broad band of Lobelia with plants of Variegated Alyssum 18 inches apart. The third mode of planting would make a very effective bed, and one that could not well be improved on, only we would have in the centre a good specimen of Coleus or Perilla, then Mrs. Pollock Pelargonium, blue Lobelia, and the Cerastium for edging.

ROSE TREES INFESTED WITH GREEN FLY (Idem).—The best remedy is to syringe them well, and whilst wet dust them with ground tobacco.

REPORTING AND WATERING PELARGONIUMS AND FUCHSIAS (Idem).—If the plants are wanted for specimens they should be repotted as often as the roots reach the sides of the pots, and before they become very closely matted, still allowing them to become slightly so before repotting. This should be continued until the plants are shifted into their blooming pots. The dowering of the plants over the leaves every day with water will not be sufficient watering. When growing freely the plants will require a good watering every day in bright weather, and every alternate day in cloudy weather, such as you give them once a week. The watering is always sufficient if the leaves do not flag, but if they do so, too little moisture has been given. A good liquid manure for watering Pelargoniums and Fuchsias is half an ounce of guano dissolved in a gallon of water, and it may be given once a week so as to show itself at the drainage, and all waterings should do the same.

GINGER CULTURE (W.).—Ginger would succeed admirably in a Pine stove, and it will do well in an ordinary stove. A compost of rich rather light turfy loam, with the addition of one-third leaf mould, would grow it well. It should have a light and airy situation, and an abundant supply of moisture when it is in free growth. The soil should not be less than 15 or 18 inches in depth, and must be well drained. If bottom heat

can be afforded the Ginger will grow all the better. A moist atmosphere, so as to encourage free growth, is necessary. The best Ginger is that from roots a year old, they being taken up when the foliage withers, which will be in January or February. You would best succeed with it in the bed, as it cannot well be grown in a pot for its roots. If the roots do not attain sufficient size in one year they may be left until the second, but they are almost sure to become woody. To have good Ginger it should be grown quickly, and the finer the plants the finer will be the roots.

FUCHSIA SHOOTS DISEASED (A. G. P.).—We do not notice anything wrong with the Fuchsia shoots, except that the points are all dead. It may have been caused by syringing with some injurious compound, or it may be by mildew, of which, however, we notice no traces. We would pinch out the points of all the shoots, and start them afresh, and if mildew attack, dust the infested parts with flowers of sulphur.

SOLANUM CAPSICASTRUM CULTURE (Idem).—It is of very easy culture, requiring to be grown in a light and airy part of a greenhouse, and in a compost of two-thirds light loam, and one-third leaf mould. It is best grown in the form of a pyramid; it should have an abundance of water, and should not be overpotted. It is grown for its berries, which are attractive in winter.

CONTORTED RADISH (J. Burton).—The Radish you enclosed is very remarkable in its growth. It has grown itself into as perfect a knot as if it had been tied by hand. We never saw a similar instance.

VINE AND PEACH CULTURE (Staff Surgeon).—To some extent every one must be taught by dearly-bought experience. No book could be written to suit all soils, all seasons, and all other contingencies. The best aid we can recommend to you is "In-door Gardening." You can have it free by post from our office if you order it, enclosing twenty postage stamps with your address. Your Peach tree shed all its blossoms from want of water to the roots.

BIRDS & POLYANTHUSES (C. S. D.).—We have nothing we can add to what we said at page 282 under this heading.

GRAPES (J. T. C.).—Write to Messrs. Webber & Co., Central Avenue, Covent Garden Market.

NAMES OF PLANTS (W. F. R.).—Cyclamen persicum.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

GAME FOWLS.

As a great admirer and pretty successful breeder of Game fowls, I read with the deepest interest any article in your Journal respecting these beautiful and majestic birds, and I hope it may ere long be the means of laying a sure foundation for properly judging and exhibiting poultry upon the same system, and by one "standard of excellence," as many judges care for no standard but their own, whatever that may be, and which pretty frequently only becomes known to the cost of many exhibitors after it is too late. For example, let us suppose Game fanciers were to exhibit their pets where "NEWMARKET" was judge; the best birds in the kingdom would most certainly be returned unnoticed; *vide* his article in your Number of the 19th ult., headed "Game Fowls' Tails," in which the writer appears anxious to impress upon Game breeders the, to me, absurd idea, that it is the "most spirited attitude" of the Game cock "to carry his tail up and fanned," and have his wings "lowered and shielding his thighs," and those that carry their tails "low and folded," are generally of a "quiet and tame disposition." I have delayed giving my comments on these statements in the hope that some "English star of the first magnitude" would take up the "endgels" against "NEWMARKET." Yet, though no one has thought proper to do so, I feel confident that such assertions cannot have met with general approbation.

Cockers are a pretty numerous class in this quarter, and such a stamp of bird as "NEWMARKET" fancies, is quite unknown to them. I had also in my possession some two years since, the last of a splendid stamp of Game fowls brought from the south about ten years ago. These birds were too

feathery for the present fancy, had low pendant tails and wings firmly set in their sides, and for as many of this strain as found their way into the cocker's hands during the space of eight years, not one was known to flinch. My present stamp of birds is neither fanned-tailed nor low-winged, and some time ago on going round my pens I was horrified to find that two had broken out, and were both blind and so mangled that I had to put an end to their sufferings.

Not satisfied with the foregoing facts, I have, since the appearance of "NEWMARKET's" article, obtained the opinion of Mr. Brown, New Scone, Perth, a gentleman of long experience amongst Game fowls, who writes me as follows:—"I have just now four breeding cocks, Black Reds, exactly resembling the 'quiet disposition' as described by 'NEWMARKET.' Now, sir, one of my cocks is about two years old, and I beg to assure you I would not enter his pen to pick up the largest gold coin without a stick or other weapon of defence." So much for the 'tame disposition' of a Game cock with low and folded wings."

"NEWMARKET" further informs us that he looks "chiefly at the fighting qualities," and cares not for the awards at exhibitions, unless they are made by really "well-known Game judges." That is very good indeed, and the last extract suggests the necessity of asking "NEWMARKET" if he has ever seen an award given to a Game fowl or fowls with "crest-fanned tail and wings lowered shielding their thighs," by a "well-known Game judge?" If he has, would he kindly give the name, so that we may compare his opinion with those of less note?

One more question and I have done. Does "NEWMARKET" really mean to tell breeders of Game fowls that a bird with a crest-fanned tail and drooping wings is the bird of courage and endurance that all of us have hitherto believed the pure-bred Game fowl to be? I must, on the contrary, assert my unbelief that the "spirited attitude" he describes is a fighting

qualification at all, and I consider such a bird a "coward," utterly unfit for exhibition, and only in his proper place when being handled by the cook.—H. GOODALL, *Lion House, Kirkcaldy.*

As my name in "NEWMARKET'S" last article is brought forward as an authority on Game fowls, I must say that I have read his numerous articles with no little surprise, as they are evidently very erroneous.

First, "NEWMARKET" says that, "In awarding the cups at exhibitions, judges are too prone to give them to stags, or cockerels, and to pullets, instead of to full-grown birds, and at the last two Birmingham Exhibitions cups were given to stags at the last Show, and to pullets at the last Show but one, when there were full-grown birds of equal merit there exhibited; and in the opinion of the best judges the full-grown birds are more entitled to cups than any birds not full-grown." Then he goes on to say, "Game fowls, though numerous, were, perhaps, scarcely so good as usual at the last Birmingham Exhibition, as, if they had been, stags would not have won the cup, for when adult birds fail in getting cups it is, I think, usually a sign that the show of birds is scarcely 'up to the mark.'"

If "NEWMARKET" has studied the prize list of the last Birmingham Show (which he ought to have done before writing such an article as the above), he must have seen that the cups were especially offered "for the best stags;" cocks being altogether excluded from the cup competition.

"NEWMARKET" names colour of skin as of importance to distinguish the courage of birds. I can tell him that I have had it in all colours from white to black, none more so than in yellow skins and yellow and willow legs.

Again, why keep the dirty, smutty, dark red face if you can improve it with a beautiful pinky red?

"NEWMARKET" would also discard the grand yellow beak and legs of our Pile Game for a washy white. It is evident his own taste is very much circumscribed; to use his own words, "he cannot see any beauty in any fowl but Game."—CHALONER.

THE REARING OF SPRING CHICKENS.

As lovers of poultry are now engaged in rearing chickens, I venture to offer a few remarks on the treatment of the sitting hen and early-hatched chickens.

Breeders of fancy poultry should never breed from birds related to each other if it can possibly be avoided. Breeding from birds nearly related renders the offspring tender, smaller, and more liable to disease.

First, as to the treatment of the sitting hen; cut a nice smooth piece of turf, place it at the bottom of the nest, and add hay or short clean straw. Some persons prefer hay, as it lies closer; but whichever is used, never omit to dust the nest over well with flowers of sulphur. It prevents the hen being made restless by parasites.

The number of eggs to be placed under a hen must partly depend on her size, and also on the size of the eggs. The weather and situation must also be considered. Some writers on poultry consider thirteen sufficient, but I should never put less under a large hen. In cold seasons and situations nine are sufficient.

If the place where the hen sits is much frequented by other hens, it is as well to shut her in, and let her come out to feed every morning, as other hens will sometimes lay in the sitting hen's nest, and this should be avoided.

During the third week of incubation the eggs should be sprinkled with warm water occasionally. If the hen hatches a small brood it can be placed with another a little older by putting the newly-hatched chickens into a basket, and placing the hen with a brood rather older than her own. Shut them in together, and after an hour or two add the younger ones.

Feed the hen liberally, as she requires it after sitting. The chickens should from the first be fed with great regularity. Every two hours they will come with an appetite. It is of no use leaving food to be trampled and wasted. Give them only as much as they will clear up. They should never be neglected, for if they once sicken, they seldom go on well afterwards. Ground oats should be the staple food; this may be wetted with water or skimmed milk. Tail wheat is much relished, and rice boiled enough for each grain to separate when thrown into meal. Rice is poor food by itself, but prevents diarrhoea and makes a change. Wheat must be sparingly used, on account of its being hard. A little bread and milk,

or a slice or two of suet pudding, will make a variation in the bill of fare. A little chopped egg and breadcrumbs are good food for newly-hatched chickens, but they can do without the egg. Stimulants are not required by healthy birds. The drinking pans should be kept clean, and where there is a dairy milk is better for them than water.

Place boards in the coop at night and remove them in the morning, have them scrubbed and replaced at night, or substitute straw. Put the coop in a fresh place every day. Cold does not affect them so much as wet.

It is desirable to have birds that feather quickly. The critical time is when they are getting the breast and head feathers. This takes place at about the third or fourth week of their lives, and they must be attended to as much as at first. In fine weather a run with the hen during the middle of the day does not hurt them after the first fortnight, as she finds them many dainty morsels. They should be fed as early as possible in the morning, as they are early astir. Grass does not hurt them. I kept three broods in a five-acre meadow in the severe frosts in March; the water in their pans was often a solid lump of ice, and out of twenty-nine only one was rather sickly, and that is recovering. On a wet soil I find the earlier chickens are hatched the better.—L. B.

THIS SEASON'S HATCHING.

As our friend "NEMO" says it would be interesting if our poultry friends would give us their experience of this season's hatching. Mine is as follows:—

Date set.	No. & Sort.	No. hatched.	Date set.	No. & Sort.	No. hatched.
Jan. 30	11 Brahmas	4	March 11	10 Brahmas	10

—PHILIP CROWLEY, *Culverton House, Alton.*

WHARFEDALE POULTRY SHOW.

THE annual Exhibition of the venerable Wharfedale Agricultural Society, for it is more than seventy years old, took place under most favourable auspices at Otley, on the 17th inst. There was a visible increase in the entries for poultry, notwithstanding the many disadvantages of an April Show. Game mustered in good force, while *Hamburghs* kept their own against all comers. In the latter extensive class Mr. Beldon, of Bingley, took the first prize in all five divisions. *Spanish* carried away the cup for the best pen in the Show. The larger kinds of fowl seem to find little favour or encouragement at this Show, for while the entry for *Dorkings* was very meagre, *Brahmas*, *Cochins*, and the *French* kinds had to creep in the "Any variety" class. The day was beautifully fine, and the attendance of visitors unusually large. Subjoined are the awards:—

SPANISH.—First and Cup for best pen in Show, H. Beldon, Goitstock, Bingley. Second, J. Thresh, Bradford.

DORKINGS.—First, J. White, Northallerton. Second, T. E. Kell, Wetherby.

POLANDS.—First, H. Beldon. Second, W. Shaw, Boroughbridge.

GAME (Red).—First and Cup for best pen of Game, E. Aykroyd, Bradford. Second, E. Allen, Baildon, Leeds.

GAME (Greys or Blues).—First, C. Travis, Thurgoland, near Sheffield. Second, D. Ashworth, Halifax.

GAME (Any other variety).—First, R. Turner, Drighlington, Leeds. Second, A. D. Edwards, Huddersfield.

HAMBURGHS (Golden-spangled).—First and Second, H. Beldon.

HAMBURGHS (Silver-spangled).—First and Second, H. Beldon.

HAMBURGH (Golden-pencilled).—First, H. Beldon. Second, F. Lees, Guiseley.

HAMBURGHS (Silver-pencilled).—First and Second, H. Beldon.

HAMBURGHS (Black).—First, H. Beldon. Second, C. Sigdwick, Keighley.

GAME BANTAMS.—First, Moody, Habbshaw, & Stead, Otley. Second, W. Edmondson, Denton.

BANTAMS (Black).—First, H. Beldon. Second, S. & R. Ashton, Mottram.

BANTAMS (White).—First, H. Beldon. Second, A. B. Peirse, Bedale Hall.

BANTAMS (Any other variety).—First, T. Nettleton, Knaresbro'. Second, J. Walker, Halifax.

ANY OTHER VARIETY.—First, C. Haworth, Haslingden. Second, H. Beldon.

DUCKS (Rouen).—First, J. Dixon, North Park, Bradford. Second, J. White, Netherthorn, near Wakefield.

DUCKS (Aylesbury).—First, J. T. Robinson, Thirsk. Second, Miss Rawson, Yeading.

DUCKS (Any other variety).—First and Second, J. Dixon.

TURKEYS.—First, Mrs. A. Fawkes, Farnley, near Otley. Second, T. Pearson, Swinsty Park.

PIGEONS.

TUMBLERS.—First and Second, H. Beldon.
FANTAILS.—Prize, D. Townsley, Bradford.
POUTERS.—Prize, W. C. Dawson, Otley.
BARRS.—Prize, T. L. Richie, Otley.
OWLS.—Prize, W. C. Dawson, Otley.
CARRIERS.—Prize, W. Shaw, Boroughbridge.
TURBITS.—Prize, W. Lund, Shipley.
JACOBINS.—Prize, W. C. Dawson, Otley.
ANY OTHER VARIETY.—Prize, W. C. Dawson.

Mr. W. Smith, Halifax, and Mr. T. Dodds, Wakefield, officiated as Judges.

LIZARD CANARIES.

I RETURN thanks to Mr. Howarth Ashton for answering my questions respecting Lizard Canaries, and from the experience he has had with all varieties of Canaries his opinion ought to be respected. There is one point, however, that I do not exactly understand. Mr. Ashton states that the cap is the principal point of a Lizard, and that a bird with an imperfect cap ought at once to be disqualified, no matter how good it may be in other respects. I cannot see the justice of the last sentence, as, if I interpret the meaning correctly, a bird with a slightly imperfect cap, though rich in quality, would stand very little chance of success against a perfect-capped bird of inferior quality in other respects. This would seem to place the spangles in no place whatever. Most judges appreciate quality as well as plumage and condition. I have frequently seen quality sacrificed to size—a failing no judge should give way to.—R. HAWMAN.

[We forwarded the above letter to Mr. Howarth Ashton, and he has obliged us with the following reply:—

"I consider a Lizard is no Lizard unless he has a cap differing in colour from the rest of his body. A bird with spangles and a little different colour on his head might be any cross-bred thing. As in Houdan fowls, which are disqualified if shown without a crest, so Lizards ought, in my opinion, to be disqualified if they have no cap; and I say a bird with a bit of a cap has in show rules no cap at all."]

ARE HYBRID CANARIES FRUITFUL?

CAN you inform me whether mules bred from a hen Canary and Goldfinch are fruitful—either a cock Canary and hen mule, or a cock mule and hen Canary? The author of the article on the Canary in Knight's "Penny Cyclopædia" makes Bechstein say that the grey of its primitive colour has undergone many changes from domestication, climate, and from union with birds analogous to it. In Italy with the Citril Finch, the Serin; in Germany with the Linnet, the Greenfinch, the Siskin, and the Goldfinch; so that now we have Canaries of all colours. Speaking of mules he says, "Before we conclude our notice of the hybrids we must again refer to the alleged fruitfulness of some of the mules, such as those of Serins, Citril Finches, and Goldfinches. The first eggs of these hybrids are said to be very small, and the young hatched from them very weak. The eggs of the next year are said to be larger, and the nestlings stouter and stronger."

A friend to whom I showed the above has put up a cock mule and hen Canary, and she is now sitting on four eggs. Some breeders that I have asked declare they have had young from such unions, others that the eggs are always unhatched.—G. SURTON.

[We enclosed the preceding to Mr. Blackston, and this is his commentary:—"If your correspondent will wait a few days he will have an opportunity of judging for himself in the matter on which he seeks for information, as his friend's hen Canary is sitting on four eggs to a cock mule. An instance of fertility in such eggs has never come under my observation; and as I apprehend that an actual case is what is inquired for, mere hearsay will be of no value. Bechstein himself only affirms that the eggs of these hybrids are said to be small, &c."

"A friend, an article from whose able pen sometimes enriches your columns, writes me this morning, 'I have seen a mule bred from a Greenfinch mule—i.e., from a bird which was the offspring of a Canary cock and Greenfinch hen, and think that Goldfinch mules will breed with the parent stock, but not between themselves; and I fancy the reason why birds bred this way are so seldom seen, is because after the first year's attempt, when the eggs are generally unfruitful, breeders

give up in despair. I entirely scout the idea of our different breeds of Canaries arising from crosses with the Goldfinch, Greenfinch, Citril Finch, Serin Finch, &c. Look at our Pigeons—are not they even more different in form and colour? and they must all have come from one kind of Dove.'"]

PAINTING STRAW BEE HIVES.

IN the books which I have read, I find very contradictory statements concerning this practice, some people affirming that it is a very good thing to do, others asserting quite the contrary; I wish, therefore, to know the opinion of yourselves about it. In my own opinion, I think there can be no harm done if the hive is painted some time before being used, and there is no doubt that it lasts much longer when painted.—CAROLUS.

[We believe painting the exterior of bee hives to be prejudicial to the well-being of their inhabitants, by confining the moisture which so frequently condenses in the hive's interior. We once shifted a stock of bees in the spring from a painted wooden box 1½ inch thick, which when weighed showed an increase of about 2 lbs. from the moisture which it had imbibed, and when the paint was planed off, the wood immediately underneath was found to be as completely saturated as if it had remained twelve months under water.]

UTILISING AND UNITING CONDEMNED BEES.

(Concluded from page 122.)

OUT-DOOR operations being thus satisfactorily completed, attention must be given to the deserted hives which have been conveyed in-doors, and from which the combs should now be removed. I find that nearly all bee-keepers are obliged to the skilled operator who will spare them the trouble of cutting out the combs, and who, by the aid of his honey knives and the exercise of a little tact, will extract them in an un mutilated condition. Getting the previously empty bucket half-filled with water, and placing it by my side for the convenience of occasionally clearing my hands and knives from the honey with which they from time to time become clogged, I set to work, and if there are no cross sticks, have little difficulty in cutting out the combs, and piling them handsomely on dishes. If there are no cross sticks! Ay, there's the rub! It's all very well when they project through the sides of the hive, so that they can be laid hold of, twisted round, and pulled out by means of a pair of pincers; but our Devonshire cottagers have, or rather had—for I have objugated and reasoned with them until I have cured most bee-keepers in my own immediate locality of the horrid practice—a plan of fixing two cross sticks in the interior of each hive, and as they were made of hard wood, pointed at the ends, and stout in the middle, and were inserted from the inside, it was impossible either to sever or to extract them. People may talk, but little things do try the temper, and I am free to confess that I have often growled most savagely, and become as cross as the two sticks themselves, when I have met with these almost insurmountable obstructions.

Supposing, however, all difficulties to be overcome and the combs fairly extracted, I next endeavour to make a bargain for what the country people hereabouts call the "deaf" comb—i.e., those portions of the combs which are either nearly empty or contain only brood or pollen with but little honey. These are generally freely presented to the operator by well-to-do farmers and others of the more respectable classes, who are but too glad of the opportunity of offering some little compensation to any one who has taken the trouble of performing what to them would have been an unpalatable task, whilst cottagers are willing enough to part with them for a moderate compensation. Unfolding, then, one of my newspapers and laying on it the piece of half-inch wood as a foundation, I proceed to detach every bit of "deaf" worker-comb, and worker-comb only, taking care to cut out each piece in as nearly a rectangular form as possible, and pile it up on the newspaper, by means of which I ultimately make it into a parcel and tie it up with one of the pieces of string. A little ingenuity suffices to pack and secure bees, combs, bag, and baggage on the platform of the little trap, and a pleasant walk homewards in the cool of the evening concludes the labours of the day. Arrived home, the hives are placed on the fl or with a block under one side of each, to insure ventilation, whilst the parcel

of combs is consigned to the kitchen to prevent its becoming chilled during the night.

The morning after a bee-driving expedition is usually a busy one, and I find my ingenuity pretty well taxed in matching together and fitting into frames, from the bars of which the projecting Woodbury rib has been removed, and their under surface coated with melted wax, the pieces of "deaf" comb. These are temporarily secured in their places by means of a couple of strips of wood, one-sixteenth of an inch thick by three-eighths wide, tacked on either side, and one or more zinc clips applied at the top in a manner which will be readily understood by reference to the annexed engraving. When patching pieces of

comb together in this way I find it necessary to pare down any parts that are of unusual thickness, and at the same time to take care that the cells on either side are left of equal length, also that the "partition wall" is not only in the centre of each bar, but that this part of every piece of comb is brought fairly and correctly in line with the "partition walls" of every other piece with which it comes in contact, and to which it is intended ultimately to be united. Crooked combs have to be set straight, and if not at first sufficiently pliable to permit of this being readily done, are rendered so by being slightly warmed before the fire.

Having if possible provided in this way at least six combs for every new stock which I am about to form, I place them in the centre of a hive from which the crown-board has been removed, and deepen this at the top by the addition of another of the same size, but destitute of either frames, or crown or floor-boards. Conveying the whole to the stand which the new colony is to occupy, I untie a hive into which the inhabitants of two stocks have been driven, and knock out the cluster of bees into the upper hive on the top of the frames of the lower one, putting on the crown-board immediately before the dislodged cluster has time to spread and scale the sides of the hive. The imprisoned queen, with her companions in captivity, remains, of course, incarcerated in the perforated box, where they are supplied with a little barleysugar, and are kept in a genial temperature on the kitchen mantelpiece for a day or two until the safety of the queen regnant has been demonstrated. The inserted hive is taken away the next morning, and the day following the combs are lifted out, the safety or loss of the queen ascertained, and the supports removed from all the combs which are then found to be fixed, but if any are not secure they are left for the present. If the queen be really missing, which, however, is but seldom the case, her place is at once supplied by her imprisoned rival; after which nothing remains to be done but to administer a sufficient supply of food, which consists of lump sugar and water in the proportion of three parts (by weight) of the former to two of the latter, mixed and boiled a minute or two. This is given at the top by means of an inverted pickle bottle, which is filled every evening until the stock reaches at least 16 lbs. nett weight, irrespective of the hive. When this is attained, any artificial supports which may yet encumber the combs are at once removed, and the whole made snug for the winter.

When driven bees are merely intended to strengthen stocks already domiciled in frame hives, there is no necessity for seeking for and imprisoning their queen, as it is so much easier to remove the sovereign of the frame hive by lifting out and examining the combs until she is perceived and captured, when she should be imprisoned with a few of her workers, and kept alive as before recommended until the fate of her successor be ascertained. Her capture having been effected, the combs are restored to their places, and the bees should then

be driven upwards through the bars into the same hive with the previously-driven bees. "What!" I can fancy some of my readers exclaiming, "drive bees upwards through the bars of a square frame hive into a round common one! and pray how do you close the openings at the four angles so as to prevent their escaping?" To this I would simply reply that I do not close them at all, it being unnecessary to do so, as the majority of the bees will rapidly ascend into the upper hive without attempting to escape, whilst any that take wing will speedily re-enter at the hive's mouth. As soon as most of the bees have ascended, the frame hive should be surmounted by an empty one, and the conjoined cluster of bees be knocked out on the bars of the lower one in the manner before described.

This, then, is the most recent mode which I have devised of effecting autumnal unions, and although I am far from flattering myself that I have succeeded in entirely obviating all risk of a quarrel, I can recommend it to the apiarian readers of "our Journal" as by far the most satisfactory of the many plans which have been tested by—A DEVONSHIRE BEE-KEEPER.

EARLY SWARMS OF THE COMMON BEE.—A cottager of Llan-rinio, Montgomeryshire, up to the 11th inst. has had two swarms. They are from the large, old-fashioned straw hive.—J. C. D.

OUR LETTER BOX.

MARKING CHICKENS (N. E. H.).—The easiest way to mark a chicken, taking it for granted an external mark is not required, is to perforate the web of the wing with a hot iron, or to mark it with worsted tied through it. The first is unseen, indelible, and almost painless. We have used it for years.

MARKING CHICKENS AND DUCKLINGS (B. E. H.).—You will find in the preceding answer our method for marking chickens. The same course may be adopted for Ducks, substituting the web of the foot for the web of the wing, or they may be safely and efficaciously marked by notches cut in the side of the bill when the birds are young.

COCHIN-CHINA CHICKENS DYING IN THE EGGS (Subscriber from Beginning).—The chickens die in the shell owing to the eggs being kept too dry. The inner membrane becomes as tough and dry as indiarubber, and the chickens cannot penetrate it. Those that do, come into the world exhausted. It is a natural and beautiful provision, that as the period of hatching draws nigh the shell used by the three-weeks sitting becomes thinner, allowing the heat to pass more readily to the impatient embryo, and making egress easier. As a rule, the Cochin egg, like all the dark ones, has a thick shell.

SPANISH COCKEREL'S COMB DROOPING—DORKING HENS ROUPY (Young Bristol).—We are very glad you are more successful than many of our correspondents in hatching chickens. We have several letters, alike cheering, that seem to be provoked by our remarks. We have small hope of the comb of your Spanish cockerel. It is the unusual development that causes it to fall over, and we know no system that will raise it up. Training can only be resorted to after growth has ceased. You must give your Dorking hens plenty of bread and ale, and some camphor pills. It is, probably, only cold from rain and frosty nights.

ROUP (B. E.).—You do not mention the breed of your fowls. Dorkings will not bear confinement, almost any other should bear that you mention. Lime whitening is most effectual. Now that the nights are becoming shorter and warmer shut up the house if there is any other place where they can roost. Disinfect the house with chloride of lime, have the floor picked up and re-made, mixing lime with the earth. Have all the perches thoroughly scrubbed with scalding water, and let the house be unoccupied for some weeks. When you get any fresh birds treat them daily for a few days with a pill of camphor the size of a pea.

DUCKS' EGGS UNFERTILE (C. P.).—It is common for Drakes to be accidentally disabled. It was, doubtless, the case with yours. That has nothing to do with the number of eggs the Ducks lay. Either their eggs are not found, or else they are taken by rats or some other depredators.

SILK FOWLS (J. D.).—Silkies are not large eaters. They like green food and frequent change. They want no different treatment from other fowls. All fowls want fresh air, especially at this time of the year.

BARNDOON FOWLS (J. Hall).—Any higgler in the counties you mention would supply you; or advertise for the large number you need.

BOILED JERUSALEM ARTICHOKE (Z.).—They are as good as boiled potatoes for fowls, and might be mixed with ground oats or ground barley. You will have seen that one or two correspondents, and they are practical men, approve of buckwheat as food for fowls. It is not much cultivated in this country.

HENS EATING THEIR EGGS (Chemicus).—There is no better mode of curing them of this habit than that you propose—namely, having none but artificial eggs left in the nests, and taking away the newly-laid eggs as quickly as possible.

EPITAPH ON A DUCK (G. A. S.).—We are obliged by your warning, but we did not promise a corner permanently, and must not admit any more verses for months to come.

ALMOND TUMBLERS (A Constant Reader).—We cannot inform you. You had better advertise for what you require, and see any birds offered before you buy them.

STEWARTON HIVE (W. F. T.).—We do not know who makes this hive now at Stewarton. If there is a maker there he should advertise.

WEEKLY CALENDAR.

Day of Month	Day of Week.	APRIL 30—MAY 6, 1868.	Average Temperature near London.			Rain in last 41 years.	Sun Rises.		Sun Sets.	Moon Rises.		Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year

6	W	[and General Meeting.]	62.0	38.6	50.3	16	25	4	29	7	9	7 41	4	14	127

From observations taken near London during the last forty-one years, the average day temperature of the week is 61.9; and its night temperature 39.1°. The greatest heat was 84°, on the 6th, 1862; and the lowest cold 20°, on the 2nd, 1865. The greatest fall of rain was 1.26 inch.

MUSA CAVENDISHII CULTIVATION.

IF prolific fruit-bearing were the test of merit in a plant there would be no question as to this being the king of fruits, whilst in stateliness of growth it admits few superiors, although its brother *M. sapientum* is taller, and *M. sapientum vitata* has a coat of more than one colour, but the garb of *Musa Cavendishii* is of the "purple." In point of size and quality of fruit the plant exceeds all its relations, giving an immense weight of fruit in a short time, more so than any other plant with which I am acquainted.

Musa Cavendishii cannot be called a plant suited to both peer and peasant, for it is solely aristocratic. It will not thrive in a cool greenhouse; it is hopeless to strive to grow it on a window shelf, or to coax it in a frame in a warm sheltered corner. If it is not in every garden, it is in many where it cannot well be grown. I have seen it in a greenhouse, in a vinery, and in many houses that, were all the plants removed, would not afford space for the growth of a good specimen. I may be told it has been grown in a vinery, and fruited in a greenhouse. I know this. I have seen it done—have done it myself; but it does not follow because the celebrated Mr. Knight grew *Pine Apples* in a house without bottom heat, and because they have been fruited in the open air, that that is the most successful practice. It is not a proof of the mode of cultivation being good, but of the plant's endurance of cold. Although the *Musa* is annually bedded-out at Battersea Park, there cannot be any hope of so cultivating it as a fruit, and it is as a fruit that I now propose to treat of *Musa Cavendishii*.

To grow well it requires a light airy house, which should not be less than 10 feet in height, and need not exceed 12 feet. The roof should not be shaded by climbers, and the plant ought to have plenty of room laterally for its magnificent foliage, not cramping it, nor placing it so near the paths that the leaves are in danger of being broken at the ends or otherwise damaged.

Presuming the grower now to have a young plant or sucker well rooted in a small pot, shift it at once into an 11-inch pot, draining the pot well, and using a compost of turf from an old pasture, where the soil is a moderately strong, yellow loam, pared off 1½ or 2 inches thick, and chopped into pieces 1 or 2 inches square; to this may be added one-third of leaf mould. Pot rather lightly, though making the soil compact, give a gentle watering at once, and plunge in a bottom heat of from 75° to 80°. Be rather sparing of water until the plant begins to grow well, then water freely, keeping the atmosphere moist by frequently sprinkling the paths, walls, and every available surface with water of the same temperature as the house. The temperature may be that of a stove, or between 65° and 70° at night, 75° on dull days, from 80° to 85° on cloudy days but with clear intervals, and from 85° to 90°, or more, with sun and an abundance of air.

In six weeks the plant will be a fine one, and should be potted forthwith in its fruiting pot or tub, and if it is to be

grown without bottom heat, then by degrees withdraw the pot from the hotbed, but affording bottom heat is the best mode of growing all our more choice tropical fruits. The compost for the fruiting pot or tub should be slightly different from that previously employed, but turf must form two-thirds of the soil, and the remaining third may be a mixture of lumps of charcoal from the size of a hen's egg to that of a hazel nut, crushed bones, pieces of grit or sandstone of all shapes from the size of a marble to that of a cricket ball, and fresh horse droppings. If these materials are all brought under cover a month before they are wanted, and thrown in a heap they can be turned over, chopped, and otherwise well mixed. The pot must be large, 3 feet in diameter at top is not too large, and it may be 2 feet 6 inches deep, but the width is a far greater consideration than the depth.

Drain the pot well, making the holes larger if small, and if a tub be used bore at least three 2-inch holes in the bottom. To make sure of the drainage acting, invert over each hole a perforated flower pot—a shallow one, such as is sometimes used for growing Orchids, and fill to about an inch above these pots with rough charcoal, bruised bones, and lumps of grit, and then put in about 3 inches of the roughest parts of the compost. Place the plant in the centre, and fill round the ball with the compost chopped roughly, pressing it lightly. Give a good watering, and if there are evaporating troughs, fill them, and keep them full until October, with guano water made by dissolving 1 lb. in 20 gallons of water, and sprinkle the floors twice a-day with the same liquid, and the walls and other surfaces with water at least as often. Do not water very freely for a few days, but when the plant is growing finely, and showing how well it likes liberal treatment, give it a 3-gallon watering canful of water every day, except on two days in the week, when, instead of water only, let it have 3 gallons of liquid manure, either the same as that used in the evaporating troughs, which feeds the plant by its leaves, and stifles all insects that are fond of the shelter which the foliage affords, or one formed by pouring 30 gallons of water over a peck of sheep's droppings and afterwards stirring well. This watering should be continued until the last week in September, or it may be longer, just as the plant keeps on growing; but when the temperature falls then the plant will grow less, and must have less water and less moisture.

This prince of the tropics is a great eater as well as drinker, and surface-dressings are indispensable. Give a coating an inch thick all over the surface of the soil and to the rim, dishing it there so as to hold water, using for this purpose fresh cow dung. The first of these dressings may be afforded a month after potting, and the dressing may be repeated every month, until the supply of water is diminished. If the roots come through sooner, give the top-dressing oftener.

As to air, *Musa Cavendishii* likes an abundance, but avoid a cool dry atmosphere. Open the lights early in the morning, and admit the sun's rays, and shut up early, so as to take advantage of the heat thus obtained before the sun has begun to sink low, or in clear days about 4 P.M.

and an hour or more earlier when the sky is cloudy. The plant, like all others, is benefited by a little air at night, but this must not lower the temperature early in the morning; the mercury must rise as the sun ascends, sink as he sinks. That is the principle of air-giving, and when this comes to be better attended to we shall have less trouble with insects.

In respect to temperature, nothing is better than that I have already stated as suitable for the young plant, only I may repeat that for the plant to grow well the pot or tub should be plunged in a bottom heat equal to the mean atmospheric temperature of the house, and the roots should not be exposed, though protected by a pot or tub, to a fluctuating heat.

By the end of September the plant will be a strong one, if all has gone on well; the watering should then be gradually decreased, and the atmospheric moisture considerably so, to induce a state of rest; but if the plant continue growing do not be in too great a hurry, but let it grow on, bearing in mind that as the days are shortening and the sun heat is less, there will not be so great a necessity for moisture and heat as when the sun heat is greater. When the plant has ceased to grow, if kept dry at the roots for a fortnight, preserving at the same time a dry atmosphere, it may throw up its flower spike. This being the case, the temperature should not be allowed to fall lower than 60° at night, and should be kept as near 65° as possible. The watering should be moderate, and the atmospheric moisture the same, until the first row of fruit is about half developed, when the watering should be liberal. Give also a top-dressing of fresh cow dung as before, and maintain a moist atmosphere; but the season being so far advanced the watering and atmospheric moisture must be regulated in accordance with the weather. The temperature, however, should be 60° or 65° at night, and from 75° to 80° by day. The fruit will be ripe in March, and it will not be nearly so fine as if the plant had had a rest before it showed fruit. The bunch of fruit, together with the barren end, may weigh 30 lbs.—not a bad return for a plant twelve months old, and it will be a valuable addition to the dessert at that season.

To have fine fruit, the plant after September should be moderately supplied with water, merely giving enough, after the watering has been reduced to a minimum, to prevent the foliage from drooping. Sprinkling the floors of the house, walls, &c., once a-day, will afford sufficient atmospheric moisture, but even this will not be necessary in dull days. A temperature of 60° at night, or not less than 55°, is ample, and from 60° to 70°, with a rise from sun heat, will be sufficient by day.

Early in January any of the surface soil which will come away easily may be removed, and a good top-dressing of fresh cow dung given, and in a fortnight the temperature may be increased till it is 65° at night by the beginning of February, increasing also the supply of water, but not giving it in any great quantities until the plant is fairly growing; then be liberal with the watering pot, and maintain a good amount of moisture in the house, but avoid having so much as to affect the safety of the fruit, which is easily destroyed by moisture condensed on the glass falling on the leaves, and finding its way into the heart of the plant. Water, atmospheric moisture, and heat should steadily increase with the plant's increase in growth and with the greater length of the days. The plant will soon show its flower spike, and it should then have a rather drier atmosphere until the first row of fruit is partly developed; afterwards water freely and afford plenty of heat and moisture. Continue this treatment until the fruit begins to ripen, then afford a drier atmosphere and a brisk heat, with plenty of air at night. The watering at the root should be diminished, giving no more water than enough to keep the foliage from flagging; but this dry treatment should not commence until after the fruit has ceased to swell. Some cut off the barren end to assist swelling; I do not practise this.

With respect to suckers, if any appear break them off close to the soil, and drill out their hearts with a sharp wedge-like piece of wood; any coming after the fruit is developed may be left, and after the fruit is cut should be removed and potted, pulling up the old plant. If there are no suckers when the fruit is cut leave the old plant a short time; it will then produce plenty of suckers, and when a few inches high they may be potted and grown in the same manner as the old plant.

I have purposely avoided mentioning syringing, for it has been the cause of my losing some fine heads of fruit. Better not syringe at all than do that, though a good syringing every evening when the plant is in its young state, and until it ceases growth, is of great benefit. Syringe in the evening only,

for if practised in the morning the sun's rays striking upon the foliage whilst wet cause serious disfigurement. Do not syringe at all after the plant shows itself thick in the centre. —G. ABBEY.

FORCING LILIES OF THE VALLEY.

I READ with interest the article in page 293, on the Lily of the Valley, and it has led me to state the method I have practised for producing a good supply from January until the plant flowers out of doors.

I would follow the culture given in page 293, and when roots have been planted three or four years, as described, they are fit for forcing. When wanted for cut flowers it is a good plan to force them in boxes, which should be about 8 inches deep, but may be of any convenient length and width. I have found the most useful size to be 1 foot 8 inches long, by 1 foot 2 inches wide. A little rough material should be placed on the bottom of each box to act as drainage, and the boxes being taken to the Lily-of-the-Valley border, with a spade cut patches that will just fit inside the boxes. Two men will lift a patch easily with a spade at each end, and put it into the box. This being done, a little rich soil should be shaken over the surface, and into any crevices which may exist at the sides of the box.

When a large supply is wanted early, it is desirable to have a quantity taken up before frost becomes severe. The roots may be placed in any shed, one box above the other, providing the crowns of the roots are not above the box. One or more boxfuls may be placed weekly in a Peach house, vinery, or on the floor of the stove. The plants seem to suit themselves to any place where they have a temperature of about 60°. A little liquid manure assists them greatly, and increases the size of the spikes.

After the flowers are gathered the plants should be gradually inured to stand in a frame or any place where protection can be given; and when all danger of frost is past they may be again planted out on a well-prepared border in entire patches, and in two years they will again be fit for forcing. When wanted for pots or vases the same practice should be followed.

—W. OSBORNE, *Fota Gardens*.

A CHAT ABOUT MY GARDEN.

SOMETIME ago, on my writing you a letter about "Fern Habits," you asked me to write again. In that letter I stated how my Ferns seeded themselves on petrified moss in a Wardenian case. They soon became too large for that case, and I have now a little Fern house in a north-east corner, where the whole of the rockwork is composed of the petrified moss; and on the side where there is water it is already fast becoming covered with the germs of the Ferns and Lichen. Possibly any porous stone would be the same, but the petrified moss has the advantage of being much lighter and more porous than any stone that I ever saw.

You encourage private people with small gardens to write about their spring flowers, and as our soil is a deep red clay, it may be an encouragement to some under similar circumstances to know that we have every bed as full now as in summer.

The soil in the flower beds is, of course, "made soil," but in spite of this many spring flowers will not succeed, particularly Anemones.

I have a chain border on grass, the chain part being a narrow gravel walk, each link surrounding a round bed 5 feet in width, and a straight edging of tile round the whole leaves little three-cornered beds between each circle. These three-cornered beds are filled with Crocuses, which are now, of course, over, but each round bed is gay. They all have a clump of Tulips or Hyacinths in the centre, surrounded by borders of white Arabis, blue Forget-me-not, yellow Alyssum, and purple Arabis, alternately; the Tulips planted according to the border colour, red with the white and yellow borders; white and yellow Tulips with purple borders; and pink with blue. Another set of beds of the same shape has the whole of each bed of the Forget-me-not, purple and white Arabis, and yellow Alyssum, with the little three-cornered beds of Cerastium clipped closely.

All this is done at very little cost, as the Tulips are very cheap, and though they must be moved before the leaves are quite dead to make way for the summer bedding plants, I find most of them do again with a few fresh ones added each year to keep up the stock.

The yellow Alyssum is cut up into cuttings in June, and

planted in a small space in the kitchen garden, where the plants give no further trouble till wanted in November.

The Arabis and Forget-me-not are laid in as they are on a piece of waste ground, and they divide into any number of tufts when required.

Of course, we have other spring flowers in mixed borders, but for bedding we find those I have mentioned give as good a mass of colour as a greater variety, and are more easily managed where the beds are required to be quite empty for the bedding plants in summer, and they never fail from the cold of our subsoil, whatever the weather may be.—E. B.

NEPETAS.

It may be useful to correspondents who are making inquiries about Nepetas, if I state my experience.

Nepeta nepetella is very dwarf and useful for an edging, but it would be a mistake to say it is blue or anything near blue, at the same time it is scarcely red. We have found it very unsatisfactory as regards continuance of bloom, frequently causing a deficiency in ribbons before the season is over.

N. tenacifolia is a strong grower and very coarse, also not blue, I should say puce, but it does not continue long in bloom. I must at the same time remark, that soil makes a great difference in this class of plants, both in height and colour.

The Nepeta we have found most useful is Nepeta carulea. It grows 15 inches high, is a good blue at first, and only changes a little to lavender by the end of the season, but from May it is a continuous bloomer. It is easily propagated by dividing the roots, and is easily managed; but it should be borne in mind, that although these plants are hardy and perennial, they must not be left in the ground from year to year and be expected to do their share in colouring for the season. They must be lifted and replanted every spring with the summer bedding plants, or if made to do duty in the spring display, which this Nepeta will, although late, they must still be moved, otherwise they follow Nature's course and last during the months in which they flower whilst in an uncultivated state; but with this little trouble even, what a boon such plants are to us in saving house-room and potting.

This Nepeta makes a good mixed bed with orange, as Calceolaria, or as a centre to a large bed on grass with an orange belt, and then, say, Bijou Pelargonium. Last season we tried Tagetes, but this did not afford colour enough. The season before in a bed containing seven thousand Nepetas, we put in the old Orange Marigold; the two colours are perfect together, but, unfortunately, the Marigold does not continue in bloom long enough.—FLOWER GARDENER.

LADY DOWNE'S VINE.

I FORWARD a few remarks upon Lady Downe's Vine, the unequal breaking properties of which are a most serious drawback, with the hope that these observations may tend to relieve some of my brother gardeners from their difficulties in the matter. After drawing your attention to a case of my own, I will endeavour to explain how I mastered the defect, and how, I am sure, others may do so likewise.

In October, 1866, we had a house of Vines replanted, amongst which were several of Lady Downe's. One of them broke well at the bottom in April, also the top four or five eyes. As the cane was about 7 feet long, I had something like 3 feet of dormant eyes; they remained in this state, with the top of the Vine bent down, till all the eyes that had started had become strong shoots. I could not rest satisfied with this state of things—a yard of naked stem, so, to make short of the matter, I cut off the naked portion, with the promise of three or four fine bunches at the top. The Vine grew vigorously, and it was pruned back last December, when I left 3 feet of the leading shoot, the growth of which during the present year has been all that can be desired.

Another Lady Downe's Vine in the same house began the same "pranks" this year as the Vine just referred to. Having my attention drawn to the matter by a gardener who was in the same difficulty as myself, I commenced to experiment with, for me, the most successful results. In pruning I find Lady Downe's one of the most hardwooded of Vines, of course when well ripened. From this circumstance and the difficulty of inducing it to bear profusely, I inferred that the bark and scale over the eye must be strong, and too tough and tightly sealed to allow of the eyes breaking evenly and at the same time. By the

careful removal with my budding knife of this scale from the least prominent eyes, I have induced them, by the access of moisture, to grow without exception, and they are now showing fruit. I may here state that they were regularly syringed, and all the others broke well enough.

The Lady Downe's Vine treated of was tied down to the wire in front of the house some weeks after the other Vines were tied up to the rafters. Nothing seemed to stir the apparently-dormant eyes till the removal of the scale.

I have also found that the stronger the Vine the more difficult it is to induce the eyes to break. I find the Vines break well enough after they have once formed spurs; it is with the young rods that the trouble arises. I have seen them wrapped in damp moss with no benefit whatever. In my mind there is no doubt on the subject now. Lady Downe's Vine should have the leading shoot stopped that the lower buds may have every chance.—A. S. K.

POLYANTHUSES.

WHY is the best of all spring flowers so much unnoticed by all your correspondents, I mean the Polyanthus?

I have been gathering together this spring all the varieties I could meet with. Some I have purchased from gardeners, others I met with in Covent Garden Market, and some I picked up out of cottagers' gardens, and a few are seedlings of my own raising; one of these last is a handsome scarlet flower, which colour I had not seen before, so that wrongly, perhaps, I look upon it as a valuable variety. I have planted out a few seedlings, and have many more nearly ready, and the interest I take in daily watching them as they successively come into flower is very great.

Hitherto I have trusted the operation of crossing to the bees, as the shape of the flower unfits it for easily effecting this artificially. Should, however, any of your readers have accomplished this operation, perhaps he will kindly communicate the result.—T. P. F.

TREES AND FLOWERS AS FRIENDS.

FOREMOST among the chief silent friends, comforters, and cheerers of man are trees and flowers. I have sometimes asked myself, Which gave me the more pleasure? Perhaps a reader will answer readily, "Flowers." But think a moment. Time and continuity are great tests of friendship, and these tests trees will bear; for although flowers soon wither—die down—perish—trees are more constant; they abide by us always; they are neighbours, I might almost say, for ever.

Not only are trees with us in leafy June (the most enjoyable month of all the year in this country, surely), in bright green splendour, but when autumn comes there they still are, clad in another garb of beauty, more gorgeous though not so glad; and even in winter who would wish to be without his treey neighbours? The perfect symmetry of a tree is never better seen than in winter, and the dullest eye and heart recognise their vernal beauty. Also there are trees which never change their leaves, and so gladden us all along the dreary season by their greenness. Moreover, in those that shed their leafy garb, see the fantastic forms of beauty which they become when decked by a hoar frost, or a snow storm, especially by the former. I would say that nothing takes off the dreary feel of winter so much as the presence around us of fine-grown trees. When all that out of doors formerly cheered us is gone—when flowers, corn fields, and green grass are no more—when hedges have become little dark lines of intersected branchlets, yet the trees are there around us still, and present with us to comfort us.

Perhaps no one can so thoroughly appreciate the value of forest trees as one born, or having lived long in the fens of England. No one, not knowing that part of our country, can imagine the utter dreariness of those treeless flats during winter. They are the real plains, the flat expanses of England. Salisbury Plain is hedgeless and treeless, but it abounds with undulations; it is not a plain, and the undulations are chiefly grass-covered—hence our Wiltshire plain is by no means dreary. Not so the fens of Cambridgeshire and Lincolnshire. The eye there wanders on weary of the flat black surface, weary of the countless water mills.

"Oh! the dreary, dreary moorland,
Oh! the barren, barren shore."

To those who know the fen country, or have lived con-

tinuously there, the presence, and I may add the companionship of trees is doubly welcome. I have been witness in former years of the great love, almost reverence, which gentlemen feel for the few trees they possess. Just on one side of the market place in a fen town stood a large Elm; how it came to be there no one knew, for saving a few Ash trees, and pollard Willows (those wretched club-headed apologies for trees), there was no timber near. Just off this market place on a bit of waste land, a kind of plester or playstow, or playing-place for young people, such as that mentioned by Gilbert White, stood the Elm. So the place, so the tree, had remained for many years, when a speculating builder managed, I know not how, to buy the site, and he determined to pull down the tree. He was asked not to do it, but in vain; and when the day came, and the fine old Elm fell, there were groans for the Vandal, and many an old man's eye filled with tears, as he saw his friend of many years prone on the earth. Oh! that strange mixture of good and bad, our human heart! it has a tender place for an old friend, if even that friend be but a tree.

Trees have touched the hearts, and inspired the song of many poets. Take as samples these two tree pictures from the pen of Wordsworth:—

"There is a Yew tree, pride of Lorton vale,
Which to this day stands single in the midst
Of its own darkness, as it stood of yore.
This solitary tree! a living thing,
Produced too slowly ever to decay;
Of form and aspect too magnificent
To be destroyed."

Then follows a second tree picture, which has been particularly commended by Mr. Ruskin.

"But worthier still of note
Are those paternal firs of Borrowdale,
Joined in one solemn and capacious grove,
Huge trunks! and each particular trunk a growth
Of intertwined fibres serpentine,
Up-coiling, and inveterately convolved."

Then, too, there are the associations connected with trees. Look at a pollard Oak of large size. How very old it is, how very slowly it has grown, how many generations have looked at it. On the hills behind my house there is one, and I often look at it with reverence, and I say, "Perhaps William III. saw you, or very likely Sir William Waller saw you, or even Cromwell himself looked at your stem, and noted your fine look." Yes, perhaps—

"When all the paths were dim,
Beneath the Roundhead rode,
And hummed a sarly hymn."

And without doubt

"You have shadow'd many a group
Of beauties that were born,
In teacup times of hood and hoop,
Or while the patch was worn."

Let trees, then, have their meed of praise. They are constant, abiding friends to us. They vary, indeed, according to season, but each variation is a separate beauty; bud, leaf, blossom, shades of green leaf, lighter at first, then darker; then come the rich autumnal tints, and then the grand visible branches stretching far and wide during the winter months, long low-hanging limbs lying above, and not far above, the backs of the clustering deer; and when the hoar frost comes, the whole tree standing jewel-decked.

But let flowers also have their meed of praise. They are the loveliest of all things while they last; bright visitors, whose coming is looked forward to with longing—bright visitors that leave behind them pleasant memories, who are talked of after they have left us. I liken perennials to old friends that come and stay with us a few days each year—old, old friends, whom we have known so many years that we cannot tell exactly when our friendship began.

Then, as flowers differ in appearance, I liken them to different friends. Some I compare to quiet maiden aunts, whom all the children gather round and love, whom the youngest, that little impatient youngest one, obeys readily, and feels happy in so doing. Other flowers, not a bit like these, so my fancy runs, are so bright and glad-looking, that I compare their visit to that of some bright-eyed merry girl—merry, so merry, that she makes the house ring with laughter—merry so merry, that she even "makes a sunshine in a shady place," and her visit has made such a difference to the quiet home-routine, that when she is gone you wonder and mark the change, and sigh to think that in a few years the world's heavy weight will subdue to a quieter tone even that merry laugh. And so of other and other flowers.

Lastly, of trees and flowers, the former we wish to have, the latter we must have, as the child will pluck the Daisies. Happily our craving can readily be satisfied, for flowers are easily carried into the heart of great cities, placed by sick beds, found or taken everywhere. No need of choice sorts for these purposes. The sprig of Lilac, the nosegay of common flowers, from a common garden, are sufficient, are welcome, and give untold happiness.—WILTSHIRE RECTOR.

FLORISTS' FLOWERS

AT THE ROYAL HORTICULTURAL SOCIETY'S SHOW—APRIL 18TH.

At the very time when all the Auricula-growers in and about London would have been thankful to have competed, positively the Society offers no prize; and Mr. Turner sends his hundred plants to be shown in the miscellaneous class for perhaps 10s. or 15s., and on the 9th of May, when he and many southern growers will have repotted their plants, then prizes are offered. Now I happen to know that in this case, before the schedules were printed, alterations were suggested by a very influential officer of the Society, and were quietly ignored, while afterwards Mr. Turner pointed it out; but nothing could be done, and so the matter remained.

Mr. Turner and Mr. James both deserve credit for bringing forward fine collections of these beautiful flowers, which require more care and attention than suit half the good folk who think themselves to be gardeners now-a-days, and who affect to despise such things as these florists' flowers. Doubtless it requires an educated eye to appreciate their beauty. Thus one good friend, who can grow a Rose as few can, said to me in looking at them, "Ah, that nasty paste!" The heretic! And another says, "Doubtless those Alpines are more beautiful;"—rubbish as compared with the beautiful stage flowers alongside of them. Where will you find such colours, such refinement, such peculiarity as amongst them? There are violets and bluish blacks amongst them that are absolutely not to be found elsewhere in Flora's domain, as, for example, Moore's Violet and Chapman's Maria; while the varied character of the foliage is itself a treat.

Mr. Turner's flowers struck me as better than ever. Sometimes I have found fault with them as overdone, and then their character is lost, for if an Auricula be coarse it is worth but little. The seedlings of Mr. Turner exhibit many good points. Colonel Chamneys is a fine grey-edged flower, somewhat in the style of Dickson's Prince Albert, and, like it, inclined to be what my dear good friend Mr. Jeans used to call "goggle-eyed." But what in the world did Mr. Turner put up that yellow self Canary for? To the border with it, along with Gorton's Stadtholder, would be my verdict. Some of his flowers were very fine:—Chapman's Sophia, with its brilliant colour; George Lightbody, in admirable condition; Glory, the glory of white edges still; Chapman's Maria, in some points the most remarkable Auricula in growth; Dickson's Unique, very peculiar in its colouring; and a number of others new and old. By-the-by, Mr. Dean, you are wrong about Bright Phoenix. It is, perhaps, instead of being new and rare, one of the oldest, commonest, and, I may add, least valued of white edges that we have.

Before I leave the Auriculas, let me thank "J. M." for his communication, and say that I hope ere long to have another chat which may satisfy him and the amateur who hails from Christchurch, Hants; but at present I hope he will pity an unfortunate who, unlike Sir Boyle Hooke's bird that could be in two places at once, is in no place at all—suspended like Mahomet's collar, and who has to superintend the removal of his plants during next week.

I am more than ever convinced that forced Roses are a mistake for the real connoisseur, the only class that really comes out well being the Teas. Of all others, they come so much out of character that even a practised eye could not in many instances say what they were. Of Tea-scented Roses, it is quite clear that three out of last year's are valuable additions—Monsieur Furtado, Bontou d'Or, and Madame Margottin. I saw nothing else worthy of note.

Must not the Cyclamens soon be ranked as a florists' flower? What variety and what beauty in that fine collection of Mr. Wiggins, who also contributed some good Polyanthus. Can nothing be done with this latter flower? The old varieties are hard to get, and new ones ought surely to be raised of greater beauty and novelty? Or is it one of those flowers that seem to defy the efforts of the hybridiser?

My visit was a very hurried one; nor could I have paid it at all unless I had been going to take duty in Dorsetshire, and so seized the opportunity in my way through. I cannot but lament that these Shows are held on a day which practically excludes so many of us from enjoying them.—D. Deal.

SLATE EDGING.

In reply to the inquiry from your correspondent "E. T." about slate edging for flower beds, I would suggest to him a form of edging which I have found cheap, effective, and very handy. The ordinary slate edging consists of blocks of slate trimmed and smoothed, and seems to me too expensive for general use. I obtained a number of the smallest-sized roofing

slates, 12 inches long by 5 inches wide, and set them on end, about 8 inches being below the surface of the ground, forming a double row of slates edge to edge, and taking care that the two edges in the inner row met at the middle of the slate of the outer row. One man can put down many yards in a day, and the material costs me less than three farthings per foot.—W. A. DARBISHIRE.

[Our correspondent lives in the land of slates, Wales.—Eds.]

CIDER AS A TEST OF THE QUALITY OF APPLES.

THE flavour of the Grape has been discussed by those who propose to establish rules for the guidance of judges engaged in awarding prizes at horticultural exhibitions; and why not also inquire into the merits of other fruits? and by carrying the investigation further than has yet been done in the case of the Grape, it is possible we may arrive at the conclusion that some of the points of excellence are attributable to causes over which the cultivator has but little control.

The fruits to which I would more immediately call attention are the two most common and hardy of our large fruits—namely, Apples and Pears, and it should be our endeavour to ascertain under what conditions the best samples of each are produced, and why fruit from one place has the reputation of possessing a finer flavour than that from another situation apparently equally favoured, as far as position and natural advantages are concerned. Samples of the same fruit grown at two places frequently differ much in quality, although the culture may have been the same in both cases; but the cause of this has not received the attention which the subject deserves. A short time ago some cases came under my notice which seemed to me to account in a great measure for this apparent anomaly, and to afford a good reason for assuming that many other cases of a similar kind may be traced to a like source.

Assuming the palate to be the criterion by which the merits of several samples of fruit are tested, it need scarcely be remarked that the results arrived at by the trial of a few dishes at ordinary horticultural shows, are not sufficient to satisfy those who may be disposed to consider the produce of one district superior to that of another, as the palate of the taster is liable to be cloyed, and the few examples the judges are able to test hardly enable them to say more than that dish No. 1 exceeds in flavour dish No. 2, and so on. The general public seldom inquires into the conditions under which the winning samples were produced, and even if this were done, other properties, such as size, appearance, &c., are taken into account in making the awards, and flavour alone is seldom regarded. Now, the case I have in view, is one in which a large quantity of fruit of one district excels that of a similar growth in another, even where latitude, position, and other natural advantages appear to be much the same. It is only just to suppose this to occur in England as well as abroad, for it is well known that certain districts in the wine-producing countries furnish wine of a superior quality to that which can be produced in neighbouring districts apparently equally favoured by Nature, and the skill of the cultivator. The exquisite quality attained in the one district cannot be matched in the other, and so often has this been found true, that we may fairly assume that what has baffled the world-be wine-producer abroad, has in some degree a parallel in this country as regards more hardy fruits. Certainly the cases that will be recorded here resemble those of the good and indifferent wine-producing districts.

In the southern and western counties of England, it is usual to make large quantities of cider from such Apples as there is no sale for, or which are not valuable enough to be retained for other purposes. This ordinary cider is almost always made of mixed fruits, a superior kind being made either of some one celebrated variety, or of choice kinds only. Of this it is not necessary to say much, as it is not the kind by which a fair comparison between the produce of different districts can be made, it being a fancy article, and often bearing a fancy price, and certain cider-makers in the west of England are noted for its production. My purpose, however, is to compare the common or ordinary article of one district with that of another, and here will be found a difference difficult to account for, and certainly so far as I can see, that difference is not likely to be ever removed by cultivation; natural causes, and these only, appearing to produce so much difference. And in the matter of the flavour of fruits of other kinds, may we not

reasonably suppose that similar causes may have exercised a like influence? Confining the matter to cider let us see the effects which are perceptible to every one in two districts in this county, and endeavour to trace the cause.

In the southern side of the county of Kent, adjoining Sussex, the country presents an undulating surface, and towards Tunbridge Wells rocks of a soft kind of sandstone crop out, and a similar kind of soil and substratum pervades the adjoining boundary of Sussex. The presence of stone, however, does not seem to be required by the Apple, but I imagine the chemical composition of the soil, whatever that may be, to be the same in most of the districts alluded to, whether the stone is present or not. The proportions of lime or chalk would appear to be a very small one indeed, while iron in some form seems to abound. In such soil the Apple grows freely, and the cider made is much sought after.

Taking another district a few miles to the north of this, we have ridges of chalk hills, with some eminences in which limestone or rag predominates. This district is not by any means less fruitful than that just alluded to; and I believe the fruit as a general rule is larger and finer-looking, and other crops also show in some places an amount of fertility not to be surpassed. Of course, in the thin shallow soils agricultural crops and grasses are none of the best, while hedges and forest trees of most kinds seem quite at home; yet the quality of the cider made from the Apples grown on such a soil is far inferior to that made in the other district, and has been established by so many years of trial and so many hundreds of judges, that the cause would appear to be due only to some difference in the chemical properties in the soil of the one place as compared to the other. Now, this is not a case in which half a dozen, or perhaps only half that number of critics, have awarded a prize, but where a whole people may be said to have pronounced an opinion of which the justice is not questioned; and when we take into consideration the fact that the fruit from the district producing the best cider is in general not so fine as that of the other district, and rarely brings so high a price in the market, the question may justly be asked, Is the same result not likely to occur with Grapes? Leaving this unanswered, the state of things described above opens up a wide field for speculation, though it is somewhat humiliating to our vanity, as proving that our efforts in the way of cultivation are after all only a secondary matter as regards the final result.

Wine, cheese, and cider are indebted to the skill of the manufacturer as well as to the quality of the material they are made from; but it is questionable whether these and some other articles were not equally good, if not better, a hundred years ago than they are now; and I may add that in the cider counties some of the kinds of Apples no more to be had, seem to be regretted. The management of cider is certainly not so well understood as it ought to be, and the instances in which it is either spoiled or nearly so are numerous enough. Most likely when greater facilities occur for the transfer of small and moderate-sized fruit from the orchard to the back streets of our large towns, where they are at all times acceptable, the quantity consigned to the cider mill will be much smaller. As it is, only the inferior Apples are made into cider; and in seasons when the general crop is light, and the price pays the grower to send the fruit to market, the quantity is still smaller. Other causes, such as the popularity of light beer, have also tended to diminish the demand for this beverage. Let it be borne in mind that my object in writing upon it was to show that soils have an influence on hardy fruits, which it is vain to look for pruning of any kind to counteract.—J. ROBSON.

HARLAXTON.

THE SEAT OF JOHN SHERWINE GREGORY, ESQ.

THIS is one of the most magnificent mansions in England, both in regard to its size and the elaborate and splendid style of its architecture. It was built by Gregory Williams Gregory, Esq., who died in 1854, just as he had finished it, and furnished it with all that could be collected of what was most rare and costly in the shape of furniture and works of art. After his death it passed into the possession of a brother, who threw it open to the public; and such was the rush from all parts of the country to see it, that a large hotel had to be built close by to afford the visitors temporary accommodation. It was during this period that Her Majesty the Queen paid it a visit; and it was surmised that it was to be purchased for the Prince of Wales. On the death of its then owner—who most injudiciously left

the furniture and works of art to one, and the estate and mansion to another—it was shut up, and the hotel stands deserted. Litigation was had recourse to in order to determine what was furniture and what was not. This has now been settled, and all the gorgeous furniture and splendid tapestries, as well as statuary, removed. We saw it in its glory, and we saw it after it had been sacked, for its treatment deserves no other name. The present owner is, however, redecorating the rooms where the tapestries have been taken down, and refurnishing them in a very elegant modern style,—lacking, however, the interest which it had before, where every piece of furniture was worthy of particular study.

There are features of special interest in the gardens at Harlaxton, where, adjoining the mansion at various points, are five conservatories, built of stone, marble, iron, and glass, most elaborately decorated, and furnished with marble fountains and basins. Some are stove conservatories, others greenhouses, and well furnished with plants. To the south and west fronts are elaborately terraced and decorated flower gardens, where enormous sums have been spent on masonry and sculpture in laying them out. Here we saw last August splendid masses and borders of all the principal bedding plants in great beauty, doing Mr. Vinden, Mr. Gregory's most intelligent gardener, great credit by the taste displayed in their arrangement as well as cultivation.

The kitchen garden and forcing houses are about half a mile from the mansion, on rather low ground. The garden walls alone cost £10,000; they are 20 feet high, built of brick, with elaborate stone dressings and copings, having niches at regular distances intended for statuary—the whole so utterly unlike anything else we ever saw before, that an intelligible description of it is impossible. Only a small part of the glass that was intended has been erected, and it is principally devoted to Peach and Grape culture. The Vines and borders stand in need of renewal. Here we saw the finest Cherry trees (Morello and May Duke) we ever beheld. Many of the Pear trees are also very fine. The management of the place, considering the staff of men kept, does Mr. Vinden much credit.—W. THOMSON (in *The Gardener*.)

PEARS.

12. AMBROSIA.—Flesh highly perfumed, melting, and juicy. Ripe in September. Switzer says it was introduced soon after Charles II.'s restoration.

Ambrosia.

13. AMÉLIE LE CLERC.—Not superior in quality. Ripens in October, and soon decays.

Amélie Le Clerc.

For full descriptions of these varieties, see Hogg's "Fruit Manual."

A NOVEL MODE OF GROWING MELONS IN HOUSES.

As this is the season for planting Melons, I think the following mode of cultivation may be interesting to some of my brother gardeners.

In the first place, plants must be raised in the usual way, which I shall suppose every gardener understands. The sorts to be grown must depend on taste. Some gentlemen are very peculiar in this respect, and I must say that Melons more than any other fruit have a great variety of flavours. I shall suppose that the plants have been potted-off; and generally for houses they have to be grown 15 or 20 inches high before they reach the wires, which will take from twelve to eighteen days, according to weather and other circumstances. This growing to reach the wires is a great loss of time, and with this object I have often seen plants drawn up with poor small stems, and they must consequently be very much weakened, and in the end not able to grow or ripen a fruit fit to be sent to table.

I shall now proceed to make the bed, which must have a good bottom heat, either from hot water or from stable manure properly prepared. The soil I prefer is a strong loam well beaten down and made quite firm in the usual way. I next bring in as many 4-inch drain pipes (not glazed—the old clay pipes are far the best, because they absorb moisture), as I require plants, place them upright on the flange end on the bed, cover the flange enough to make them stand firmly, and then fill the pipes up with soil. This I make firm, and then I plant out in the small end of the pipe.

I have known good, large, well-flavoured Melons grown in this way in much shorter time than without the pipes. I hope some of my fellow blue-aprons will try this mode of cultivation; it saves time, does not weaken the plants so much as the ordinary mode, and watering can be better regulated. The roots will soon find their way down the pipes into the bed, and the plants are not so likely to rot off at the collar.

There are several good reasons for growing Melons in this way. First, they can be planted out and afterwards stopped at two or three eyes, and they will commence to throw out laterals at once; fruit can be set in about eighteen days, whilst in the general mode of management the plants would have only reached the wires; and, lastly, at the period of ripening one can regulate watering to a nicety, and on this, together

with sun and air, depend the flavour and quality of Melons.—
J. R. P., *Bickley, Kent.*

DESTROYING ANTS.

I HAVE read in your correspondents' column the question asked, How to destroy ants? and the answers, effectual in their way, were dangerous, as poison was to be employed, spread in their walks or near their haunts. My house was at that time infested with these insects, and has been so more or less through the winter, but the last few fine days have brought some hundreds out, so that scarcely anything could be kept in a cupboard, which they had access to through holes in the wall. I laid some moist sugar near the holes, and after about an hour I returned, and could not see the sugar, as it was entirely covered with ants of all sizes from a speck to a barley grain. I then with a flat-bladed knife destroyed every one of them, and on looking to-day at some more sugar laid in the same manner not one ant was to be seen. I, therefore, conclude that I by means of a little moist sugar enticed a whole colony of these insects, and destroyed them without the use of any dangerous poisonous mixtures.—EDEN GROVE.

WORK FOR THE WEEK.

KITCHEN GARDEN.

WE seldom have finer weather at this time of year for all out-door operations. Several correspondents state that the wall fruit promises to be a large crop, and appearances warrant the same conclusion in regard to the standard fruit. *Celery* and *Lettuce*, plants lately pricked or planted out—indeed, any small plants which have been lately transplanted, will now be in danger if the weather be dry, and they must be regularly watered, and so must crops of *Turnips* and other seedlings as they are coming up. *Cauliflowers*, when transplanted, every care should be used not to injure the roots, and the plants must be well supplied with water until they become established, as neglect in either particular will probably cause them to flower prematurely, and thus occasion the loss of the crop. Even when the plants are fairly established they must never be allowed to be dry at the roots, and an occasional soaking of manure water during dry weather will greatly benefit them. *Onions*, see that you have a bed or border prepared to plant out the thinnings by-and-by, and sow a bed of the Silver-skinned in light poor soil some time soon to come in for pickling. *Peas* and *Beans*, keep the ground between the rows well stirred and free from weeds. In dry weather mulch with manure for 18 inches on each side of the rows, giving a liberal supply of water when necessary to keep the plants vigorous and to prevent mildew. The growing crops of *Peas* should never be allowed to suffer from the want of water. In exposed situations strong stakes driven in on each side of the rows of Broad Beans, and common tarred cord stretched along them, will be useful to prevent the plants being beaten down by the wind. Where water is a scarce commodity many shifts must be resorted to in dry weather. The best substitute for heavy watering is to mulch with short grass between the rows of advancing crops. This will save much time and labour. Even when water is plentiful, simple as the operation of watering is, few things are worse performed. One good watering that will saturate the soil, provided the surface is mulched or stirred afterwards, is worth a dozen mere sprinklings, because the one watering will often be sufficient, while the many waterings are generally prejudicial. In the one case the roots are discouraged from coming to the surface, the dryness of that surface prevents rapid evaporation of moisture from below, and the roots are, therefore, enabled to absorb freely to supply the exhaling foliage. In the other case, surface roots are for a time encouraged, but are speedily checked, as the sun quickly causes the moisture of the surface-watering to evaporate.

FRUIT GARDEN.

Keep a regular eye over the wall trees, and see that no insects or other vermin establish themselves there; the young shoots must also now be well attended to. Never cut-out or otherwise prune too much of the summer growth at once. It is much better to begin in time and stop the strongest shoots only at first, and so on through the growing season.

FLOWER GARDEN.

The importance of grouping plants in flower gardens according to their complementary colours has been repeatedly insisted on. The leading principles of this system of manage-

ment are contrast and symmetry—contrast such as will be produced by placing the complementary colours pretty closely together—as scarlet with white, purple with yellow, orange with blue, and so on with the various shades of these colours; and symmetry, such as will result from every bed having a corresponding one in form and disposition when beds are planted with flowers of the same colour. Where beds are planted on grass and without a corresponding one near them, they should be belted with the complementary colour—as blue with an orange margin, purple with yellow, and scarlet with white; or as green is the proper contrast for scarlet, beds of that colour may be left without a margin, and white, under such circumstances, used as a distinct bed. Where beds are on gravel, which is of a warm colour, a cold colour should be the most used, as blue, purple, and white, which for floricultural purposes takes the place of green; or if warm colours must be introduced, it is indispensable that they be margined with cold colours. In large gardens where there is a great preponderance of green—as large lawns, or trees, and extensive lakes, more especially if the trees are large to throw considerable shade, nothing but warm colours should be used—as scarlet, orange, and yellow, and these should be in large masses and stand out prominently in the foreground of the scenery, and especially near the water. Whoever has walked through the metropolitan parks will have noticed how much more cheerful is the aspect of the water in St. James's Park, than it is in the Regent's Park, or Kensington Gardens, and this is because the water is surrounded by gravel which gives the appearance of warmth. Watering and thinning the young plants are the principal work at the present time; but double Primroses, Polyanthus, &c., which are out of bloom and being removed from the flower garden, must be parted, planted in rich soil in a shaded situation, and watered. This is a good time to tie-out or peg-down the branches of American plants, so that the young shoots may take the right direction when they begin to grow. In high and exposed situations the plants must have water, or they will be unable to expand their blossoms properly.

GREENHOUSE AND CONSERVATORY.

Now that the season is so far advanced that many of the older kinds of plants often wintered in conservatories may be removed to temporary shelter, no plant, except in flower or a fine specimen, ought to find a place in the conservatory from this time to the end of September. As the spring Heaths go out of flower remove them to cold pits. If they are young plants this is the best time to prune them. As soon as the growth of forced plants of *Rhododendron arboreum* is nearly over remove them to a cool shaded place, as this and many of its hybrids are easily induced to make a second growth, and, consequently, produce no flowers next season. Keep all plants well watered and in good shape. Encourage greenhouse plants to make a rapid growth now. Keep the house warmer and more moist than is generally done, and see that this moisture does not deceive you. In watering, many pots may look wet on the surface and yet be dry below. Train, pinch, and prune them as circumstances may require, and, above all, keep them perfectly clean.

STOVE.

Some of the more free-growing plants that were potted early will now want another shift, and you may give them more pot room now. Many young plants nursed in pits through the spring will now be too high, or the pits may be wanted for other purposes; remove them to the stove, and for the first week or two imitate the pit culture for them as far as your house will allow. Keep them more shaded than the rest of the plants, syringe them twice a-day, and keep them as far from the ventilators as you can.

FORCING PITS.

Most of the spring-flowering plants are done with in these pits. Roses will now bloom in any close house or pit. There are many plants, however, that may be more or less forced for the conservatory all the summer through, especially those called intermediate or half-stove plants. Camellias, Azaleas, and *Rhododendrons* that have been early forced may be grafted as soon as the young wood begins to become hard. Of all the modes of propagating rare plants, grafting is the easiest and requires the least time and attention.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Saving Seeds.—When a person has the chance it is well to save a few seeds of a favourite kind of Pea, as then it is more

to be depended on than what is sent out by general seedsmen, though our own experience and practice would lead us to the conclusion that seedsmen spare no pains nor labour in having everything good and everything true to name, and no doubt they find that intelligence and integrity combined will pay. Mistakes will, however, at times occur. Just think of the results of a heedless man shifting a few numbers or tallies inconsiderately. Most seedsmen this season, we believe, have told their customers to sow some seeds thickly. Last autumn was very unfavourable for harvesting seeds, and no doubt from being imperfectly ripened, or to make up bulk with older seeds, the crops of some things do not come up so freely as usual, and in such cases will save thinning, as in general it is a fault of gardeners to sow rather thickly, though it is always more pleasant to thin out than to plant and make up. Partly from the seed decaying, and partly from the inroads of vermin, we have been forced to dig down one row of Peas and sow another kind, for if we do stick our Peas nothing looks worse than a thin row. In this respect we often minister to a general prejudice, though we know better. Were we certain that our seed Peas would be let alone, instead of scattering the seed along a row we would gather a heavier crop by planting all our larger Peas in a single row 2 inches apart.

Vegetable Seeds.—Making every allowance for birds finding their way underneath the netting, the seedlings are threatening to come much thinner than usual, showing that, like larger seeds, as Peas, the late harvesting time had told upon them. We do not see that any seed has been maddled with that was treated with a dusting of red lead before sowing, but that expedient will not prevent the different kinds of *grass mice* eating down the young shoots of Peas, &c., after they are fairly above the ground. We shall be glad of any information as to the best means of destroying grass mice, as even some parts of our lawn are riddled with their runs and holes, and trapping does little to thin them, and they can scarcely be coaxed to touch anything in the way of a bait that would hurt them. We caught great numbers at one time with nooses made of fine wire, and even of strong hair; but we should be afraid to venture to use them now for fear of younger and more valuable animals being caught. We have some beds with stake edgings covered with ivy, and these are a favourite rendezvous; in their vicinity it would be folly to plant some kinds of *Verbenas*, especially *Purple King*, as the mice are nearly as fond of that as rabbits are, and the latter will find it out if they have the chance among hundreds of other *Verbenas*, if as many are grown.

We saw lately what was a beautiful plantation of young Laurels almost destroyed, for it was cut and peeled from the surface of the ground nearly to the tops of the plants, and the plants are now all withered. If there is a chance at all, the plants must push up afresh, and then run a similar risk. In most cases this mischief had been done by the common house or barnyard mouse, and we have caught these in great numbers by sinking pots inverted inside, one-fourth filled with water, and a float on it, supplied with burnt meal or toasted cheese. When the mouse got his feet wet he could not lay hold of the sides of the pot. Glass would be still better than earthenware. Such a contrivance even when baited with the most tempting green delicacy did little to entice the grass mouse. The best helper we ever had was a little dog, who took to the work with much zest, watching their holes for most of the day, and killing numbers of them. If any reader will acquaint us with a good way of thinning grass mice many will be thankful, for in some places now the mere act of culture is of less importance than knowing how to give the plants grown a fair chance of having their natural enemies kept at a distance.

Asparagus.—We have just cut over a young piece of this for use and to encourage the side shoots to push, so as to afford us a supply a good while longer. In small gardens this is not nearly so much grown as it ought to be, as few vegetables are better for a late spring supply, coming in as a change when the Brussels Sprouts are nearly over. Shoots about the thickness of the little finger, and 6 or 8 inches in length, boiled just like other Greens, are little inferior to Asparagus in flavour, and will compete with a stubby list of Sea-kale in all but the colour. Our earliest have been a good long ago, but a few rows of late ones were topped for use a week since, and the side shoots are now growing well. All Hales have something in common, but this well deserves its name. It does not take so much room as the Scotch Kale, and is of but little use as winter Greens, but in April and part of May it is very useful as a change with sprouts of Borecole, young Cabbage, and Broc-

coli, holding its own generally until the Cauliflower compels obedience from all rivals. Brussels Sprouts and Borecoles are the main dependence in winter, and the coloured or variegated kinds of the latter are just a little more tender than the green, and if carefully cooked will present their colours at the table.

Sea-kale.—We shall gather a week or two longer from that under the common garden pots. We detailed how we stuffed the inside of the pot with rough hay, leaving only a hollow in the centre, and dispensed with covering outside the pot. The utility of this was found in the late frosty mornings, for where the pot was set over the plant, and there was no hay in it, the Sea-kale instead of being white was frosted black. We want to have none of this trouble with pots in spring, and, therefore, we have planted some beds 4 feet wide, with two thick rows of plants in each, and made trenches between the beds, 2½ feet wide at top and 1½ inches at bottom. These when we have time we will fill with riddled ashes, and in winter we shall lay the ashes on the bed 5 inches deep over the plants, and that will cause them to be sufficiently blanched, and if merely once cut in the season, the same plants will last many years. Most likely we will put some litter over the bed and in the trenches in winter, and that will be rotten enough to do for manuring the beds in May, when the ashes will be all turned into the trenches again.

In planting these beds, we cut all the ends of the roots into pieces 6 or 8 inches long, and planted them in rows a foot apart and 8 inches from each other in the row. These will do for thinning next year. We will fork over the ground as soon as we cease cutting among the established plants, and where an extra shoot has strayed, cut it near home, add a little dung whilst forking over, and strew a little salt between the rows when finished.

Asparagus.—We should have salted the ground in which this is grown, but could not obtain the salt in time, and now we will wait until we see the rows, as the heads are beginning to appear, and the salt would injure them if it fell on the points of the young shoots. This sprinkling in spring does much to keep down weeds; but the time when as much salt as will just slightly whiten the ground does most good, is a fortnight or so after ceasing to cut. Sprinkling with salt affords this plant and Sea-kale a substance which they obtain in abundance in their wild state. We regret omitting the sprinkling ten days or so before the shoots of the Asparagus appeared, as nothing so effectually banishes slugs and snails, which when plentiful soon mar the best shoots.

Tom Thumb.—Little Gem in the orchard house, in pots, is filling its pods well, but though nice and stubby in growth, and showing signs of throwing out side flowering shoots at the joints, it does not seem to bloom and bear so freely at first as our old friend Tom Thumb. Little Gem is superior to the Tom Thumb in flavour; but then at an early period quantity is an object, even if the quality be not so much to boast about. We think we have erred, too, in planting rather thickly; and another season, if using 16-inch pots, we would have a circle 1½ inch from the outside, and have the Peas about 3 inches apart.

Pea-staking.—In the dry days that followed the rain, we had the most of this work done that could be done, moving our wire netting to accomplish it. The ground was nicely stirred up, but not deeply, by the sides of the rows before staking. We have had much trouble with Peas, with the exception of those we planted out, which have done well, especially after the watering referred to last week. In staking, we saw lately that one of our friends recommended crossing the sticks to each other at top, so as to resemble an acute-angled triangle, of which the ground between the stakes at bottom should be the base. Our staking is often done the same way; and almost every staker will resort to that mode, because it is the most easily done, looks very well when done, and answers well in every way until the Peas get to the top of or above the stakes, and coming through near the top are as helpless in the wind as if they had never been staked at all. The Peas will be better sustained and more safe at gathering time, if the stakes, where they diverge from the perpendicular, lean outwards from each other at top instead of leaning towards or touching at top. We prefer the tops of the sticks to resemble the sides of a cup rather than the point of a wedge, though we allow that the latter to many would look neater. We know that the cup form will be best for the Laurel of the Peas in a brisk gale.

Dung Beds.—At the risk of being wearisome we will venture a few sentences with reference to cases submitted to us by three correspondents. The first, even with well-prepared dung,

cannot keep up bottom heat without frequent turning and making fresh linings. The second goes on pretty well with the back of his bed, but the front soon becomes cold, especially if much rain falls and runs down from the glass; and the third is in straits whether he should make his bed on an elevated piece of ground or sink it partly below the ground level, and adds that he must make the most of his material. To the first we would say that we scarcely trouble ourselves with linings, if at all, until towards the end of summer; but then we, as it were, make bed and linings at once by having the bed some 18 inches wider back and front than the frame. We keep banking up on that well up the outside of the frame, so as to supply atmospheric heat without increasing bottom heat. We save the heat also by sticking laurel boughs, or placing old hurdles thatched with laurels, round the sides of the bed—a matter of importance, especially in cold windy weather. We think the plan on the whole saves labour and trouble, but we by no means expect or wish that others should think and act just as we do. We would at once change if we could do better and on the whole make more of our material.

What our second correspondent says is perfectly true, and holds good with all frames on dung beds. In heavy rains the water will run from the glass on the lining or front of the bed, and it will soak inwards until it robs the front of the bed of its heat. The simplest plan to obviate this is to have a board or boards sloping in front to throw the rain water off. The next simplest, and better, is to have two slips of wood the length of the frame, 3 inches wide, and three-quarters of an inch thick, two of the sides bevelled, so as to form an acute angle when joined together, and thus make a handy spout. A little tar run along the bottom of the letter-V spout will make it all tight, and even a little clay will do, and the water can thus be easily taken away. We say nothing of what would be better still—a small spout of tin or zinc, but the wooden one will answer admirably, and do much to prolong healthy sweet heat in hotbeds.

To our third correspondent we would say that in early beds we prefer that they should be partly sunk, say from 18 inches to 2 feet or 30 inches, partly because they are more easily worked and managed, when you have neither to stoop too low, nor raise your body too high, and partly because what is thus sunk is less exposed to wind and air, and is not, therefore, so quickly cooled. Another reason is that great mounds of dung hotbeds raised wholly above ground make a striking appearance, and look like something that never could be exhausted; but half sunk in the ground they become very petty-looking, and hardly arrest the attention of those most intimately concerned in supplying the gardener with manure, and the best of it is they do not contain a barrowload of material the less, though thus so unobtrusive in their appearance.

FRUIT GARDEN.

Went on nailing as we could, when other work and weather permitted. One advantage of all the pruning being done is, that the mere nailing can be done more pleasantly than in winter, and such as Morello Cherries can have an extra pruning, as the wood buds can now be better seen. A press of other matter has kept us back here, but we will soon have all straight. The few laurel boughs have not quite saved Apricots from the frost, but a considerable number seem all firm. The wet followed by frost did the mischief. Hence when protected at all, a covering to keep the blooms dry is the chief precaution necessary. It requires a sharp frost to hurt an Apricot bloom, if it is dry. Peaches have suffered little, but we see some coming on the young shoots, and will give a good washing with the garden engine during a fine day. Cherries and Plums seem all right: Pears are in bloom, and Apples beginning to open, and looking well, as from our little trees we have kept the birds off. In a small orchard not worth keeping, and too small to be worth watching, hardly a wood bud, let alone a fruit bud, is to be seen.

Orchard Houses.—Merely for shelter these can now be erected so cheaply, that in all cold places they will be much cheaper than protecting against the open wall. On trees on walls, and in pots, the young fruit will give plenty of work, being as thick in many places as ropes of Onions. In the latest houses, the bloom falling from Cherries, Plums, &c., a slight syringing was given, and after warm days a good syringing was afforded to the more forward trees, and once or twice a-week the syringing was done with soft water as clear as brown brandy. We would rather keep insects from appearing than have to destroy them afterwards, and as yet we have succeeded well. We noticed to-day a curl on the point of some Plum

shoots that told of a caterpillar being housed there, and these shoots were at once carefully nipped off, held firmly, and taken to the nearest fireplace. The shoots needed nipping at any rate. The syringing two or three times a-week renders less watering necessary.

In the most forward orchard house we moved some Strawberry plants in pots set on rich leaf mould near the front, moving them much against our will, because when the roots begin to come out at the bottom of the pot it checks the plants to disturb them; but they had thrown up such an abundance of strong flower trusses that they would have injured each other without more room.

Moved a lot of British Queen into a pit, setting them on a bed surfaced with fine soil, as if the roots run through now we hope it will not tend to encourage the leaves too much, instead of throwing more strength into the flower trusses, as would have been done at an earlier period. We were obliged to fumigate a fine row, just setting well of Keen's seedling in the late vinery, as some dry began to cluster on the pedicels of the flowers and young fruit. Now, whence came these insects? The house was filled with flowering plants, and nothing of the insect on them. The Strawberries a few days ago were equally clean, and now they would soon have been smothered if let alone. Had the eggs kept their vitality all the winter and owed their development to the greater heat of the house? Some plants in the first orchard house are nearly as forward, only a few days behind, and as yet nothing appears on them, but we should not be surprised to see some there too in the course of a week. Heat is the great friend of these marauders, and cold is their great opponent. Extremes are often valuable: hence, we value a cool temperature and hot-water washings, especially when plants are in comparative repose, as good resources for keeping insects aloof. We were obliged to smoke the Peach house because the Strawberries when at about the same stage were also visited in a similar manner, though a day or two before not an insect was to be seen on them. When only a few appear the fingers can soon settle them, but when numerous there is nothing like smoking, and generally doing it twice. Strawberries for two or three years have made us resort to this disagreeable work, when otherwise the houses wanted nothing of the sort. Proceeded with thinning and regulating vineries, &c.

ORNAMENTAL DEPARTMENT.

In potting Ferns and other plants, lardening bedding plants, and getting those potted that do best with a ball, as Heliotropes, and making the last cuttings of those things likely to be useful, the most of our time has been taken up, but there was little different from what has appeared in recent numbers. We put in some hundreds of little slips from the bottom of the *Cineraria maritima*, as many of the old plants in low ground have died, and because these cuttings, which will be good plants ere long, will have the fine silvery foliage which seedlings never have the first year. These cuttings will average 2 or 3 inches long, and they were taken off with a little heel just as they were showing on the old stems and coming above-ground. They will have a gentle heat.—R. F.

TRADE CATALOGUE RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*General Spring Catalogue, 1908.*

COVENT GARDEN MARKET.—APRIL 29.

We have still a great abundance of produce when compared with the demand, which, however, is somewhat improved, and strawberries have slightly advanced in price. French beans, etc., comprise Peas, Broad Beans, Cauld-wers, Artichokes, young Cabbages, Turnips, and the usual samaras, with a few but not many Cherries in the market. Old Potatoes are a heavy trade: good new Liston range from 6d. to 7d. per lb.

TO CORRESPONDENTS.

*. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix upon the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

GARDENERS' WAGES NEAR LONDON (W. Amos).—It is quite impossible to give an opinion as to the probability of employment or the remuneration, so much depends upon the skill possessed by the applicant and other circumstances. You had better write to some of the leading florists and nurserymen near London.

HEATING A PINE PIT (Southerner).—By the same pipes you cannot regulate your heat—that is, you cannot have top heat when you like and bottom heat when you like, the one independently of the other. For this purpose you must have separate pipes for top heat, and separate ones for bottom heat, with valves to regulate at pleasure. For a Pine pit to be used continuously for Pines, or even for crops of Melons at times, but chiefly for Pines, the plan proposed is more simple, and does away with all valves and regulation, and as the water circulates all round for top heat first, before it enters below the bottom of the bed, you will always have enough and never too much bottom heat. It would be simpler still if you took two flows along the end, along the front, and along the other end, and then returned these beneath the bed for bottom heat. We have seen several pineries thus worked most successfully, and there is no trouble with valves or taps, therefore we say that the plan will answer. However, if you would rather have each set of pipes under control, that you can do with valves.

KEEPING LATE GRAPES.—OBTAINING A CONSTANT SUCCESSION OF GRAPES FROM TWO VINERIES (A Reader).—For Lady Downe's and other late Grapes to hang well until March, they should be perfectly coloured and pretty well ripened by the beginning of October. By having Hamburgs, &c., in your late house there may be a constant succession from two houses, a late and an early one; the Vines in the one forced early, those in the other forced little, but allowed to break naturally. A third house to come in between would give a better supply. There need be no difficulty as to the pruning of the late Vines if even the Grapes hang long, as the Vines could be disbudded when you could not cut, and all the disbudded parts removed when the Vines were in leaf, and they would suffer little or nothing. The Royal Ascot Grape bears out all that has been said in its favour.

GRAPES SHRIVELLING WHILE YOUNG (Rosslyn).—The young bunches were much dried up, but we could discover no traces of the Vine mildew. We think the shrivelling up of the bunches is owing to two causes—a heavy crop the preceding year, and unripeness of the wood, owing to the wet and dull autumn. The roots may also be getting deep enough. Give more dry heat to ripen the wood this season.

UNCOVERING AN OUTSIDE VINE BORDER (One in Perplexity).—Were we in your case, and the Grapes just beginning to colour, we would examine the outside border, and if moist enough we would let well alone, and allow the covering of leaves, &c., to remain until the Grapes were coloured. If the border was too dry we would clear a piece, water, and turn the covering over, treating all the border in the same way; but if moist enough we would let well alone for another month or six weeks.

CUCUMBERS NOT SETTING (For-man).—Cucumbers are so uncertain. We have eight or nine plants that would kill themselves with fruiting, we have several others doing little, though almost as old. Be content with 65° at night, give less manure, and be sure the roots are not dry at the bottom of the soil.

ZONAL PELARGONIUMS FOR EXHIBITION (Amateur).—Your compost is correct, but quite rich enough. Eleven-inch pots will grow a large plant, but if desirous of having the plants very large, shift them without delay if to be at the best in the beginning of August. The flat form of training will have the best effect; if to be seen with a face, we prefer the centre to be highest, and gently rounded so that the top shall be circular.

GROUND VINERIES (C. C.).—The proper width of a ground vinery is from 30 to 36 inches. In the first case the height at the ridge may be

16 inches, in the second it should be 20 inches. They are best made in 7-feet lengths, and they are cheapest if without bars or hinges. As regards cost, Mr. Rivers had a couple of 7-feet lengths of barless ground vineries, 3 feet wide, with two closed ends, painted and glazed with 21-oz. glass, for £1 19s.; so you can calculate what the foot will cost, and allow a little more for inexperienced workmen or carriage. As to position, the ground vinery should stand north and south, or nearly so, presenting one side to the morning, and the other to the afternoon sun. You will gain nothing by placing it against a wall. If you have a south wall you had better cover that with a fixed roof. Common slate will answer well for the bottoming of a ground vinery.

COLLYER AND ROBERTS'S TOBACCO TISSUE (G. F.).—We have seen Mr. W. Paul's and many other testimonials in favour of Collyer & Roberts's Tobacco Tissue. Those testimonials state that fumigation with it is quite efficacious in destroying both thrips and green fly.

HOTBED (R. W. H.).—Your note is an advertisement, and we have many similar, but are obliged to decline inserting them.

CELERIAC CULTURE (S.).—The cultivation of Celeriac is the same as that of Celery—that is, the seed should be sown at the beginning of March in a pot, to be placed in a mild hotbed or house where there is a gentle heat. The seedlings should be kept near the glass, and be well hardened-off, and when they have each a pair of leaves they should be pricked-out in a bed of rich soil. Shade from sun until the plants are again established, and water freely overhead every evening in dry weather. They should remain thus until they are of sufficient size for planting out. We consider it best to grow Celeriac in beds 4 feet wide, with 2-feet alleys between them, the soil being taken from the beds about 6 inches deep, and laid in the alleys, its place filled with well-rotted manure and leaf mould, and the bed dug over twice or thrice, so as to thoroughly work in and mix the manure and leaf mould with the soil. In this the plants should be planted in rows across the beds, six plants in a row, and the rows 15 inches apart. A good watering should be given, and when established a soaking of liquid manure may be afforded frequently, especially in dry weather. A little of the soil from the alleys may be put between the rows of plants from time to time, but the earthing altogether should not exceed 6 inches, as it is not the blanched stalks which are wanted, as in Celery, but the turnip-like portion of the stem, which is excellent for soups, and in every way better than Celery stalks. We have grown it many years. In severe weather it should be protected with dry litter.

CRICKETS AND SLUGS IN FERNERY (E. M. H.).—To destroy crickets, spread phosphor paste on slices of bread, and lay them down in the places the crickets frequent, and in the morning the latter will be found dead, and of a bluish colour. A sixpenny pot will clear your house. The best means of destroying slugs is to search for them after dark with a lantern, and they may by that means be destroyed, or fresh cabbage leaves may be placed at night near the plants attacked, and in the morning the slugs will be found under them. Fresh leaves should be used every night. Frogs are great devourers of worms, and of slugs occasionally. You might introduce a toad or two with advantage, so as to keep down woodlice. Neither frogs nor toads will do any damage to the Ferns. They are not vegetarians.

DYING PELARGONIUM LEAVES (A Young Gardener).—The leaves of Pelargoniums when dried retain their colours. The best means of drying is to place them between sheets of blotting paper, and press them gently. The paper should be dry, and changed every morning and evening, fresh or dry paper only being used.

TWELVE SELECT HEATHS (Idem).—Cavendishii, Gemmifera elegans, MacNabiana superba, Fernigiana major, Picturata, Obbatia, Massoni major, Shannoniana, Tricolor dulciflora, Ventricosa grandiflora, Willmorei superba, and Vestita rosea elegans.

THYSANOTUS GRANDIFLORUS (A Subscriber).—Thysanotus grandiflorus is not more tender than T. proliferus. Both succeeded admirably in an airy greenhouse, having a position near the glass. When growing it cannot have too much water, but when the foliage attains its full size diminish the supply of water, and place the plant in the full sun. In winter keep it dry but near the glass, but do not allow the foliage to perish prematurely from want of water. Keep it under-potted rather than over-potted.

WATERING ROSES WITH SOAPSCUDS (One to whom Water is an Object).—You may water your Roses, and indeed all kinds of plants, with soapy water from the bedrooms, but if from the laundry it must be used with caution, as it very often contains so much soda as to be injurious to vegetation.

LAWN BECOMING MOSSY AND COARSE (R. Ballbrook).—We would advise you now, in moist weather, to give the lawn a thorough scratching with an iron rake, and then put on a light dressing of very rotten manure. Afterwards give another good raking, taking off all the rough parts of the manure, and sow forthwith 4 lbs. of Snickling Clover, 4 lbs. Cynosurus cristatus, 2 lbs. Festuca duriuscula, 2 lbs. Poa nemoralis, and 1 lb. Lotus corniculatus minor for one acre. If the ground be full of weeds grab them up, and if full of tufts of coarse grass remove them, sowing twice the quantity of seed per acre; roll well when the ground is dry, and leave it untouched for a month, then keep it well mowed and well rolled.

DESTROYING WOODLICE (Mary Duer).—The best means of destroying woodlice is to place a boiled potato, with a little hay wrapped loosely round it, in a small flower pot. The pot may be laid on its side at night; examine it in the morning, and shake the woodlice into a bucket of boiling water. Another mode is to cut a large raw potato in halves, dish out the centres a little, place the pieces on the pots hollow side downwards, and so that the woodlice can get under. These pieces if examined daily will be found to have many woodlice under them. The baits will last a long time. A few toads placed in the house would speedily thin the ranks of the woodlice. They are difficult to poison. A little arsenic may be mixed with dry oatmeal and laid on pieces of slate near the places frequented, but poison requires great care. Be careful, and keep it out of the reach of domestic animals and fowls.

FLOWERING EUPHARIS AMAZONICA IN AUGUST (A Young Gardener).—The plants to bloom in August should now be repotted and plunged in a good bottom heat, encouraging growth by giving plenty of heat and moisture. This should be continued until the end of June, then keep dry for a fortnight, and it is likely the plants will show for bloom, when, of course, every encouragement should be given. Possibly the plants may show flower earlier; if so, they must be retarded, and if in a suitable-sized pot

we would not report them, but grow them on slowly, forwarding or retarding them as occasion might require. We could not well give a more definite opinion unless we saw the plants and knew when they last flowered.

BALSAMS AND CELSIOS FOR AUGUST-FLOWERING (*Idem*).—Now is the best time to sow Balsams to flower finely in August. The plants will be fresher in foliage and stronger in bloom than those sown in March. The Celosias are best raised from seed sown in March; but we would sow more seed now, and encourage the plant, making a selection of the best.

SELECT VARIETATED ZENAL PELARGONIUMS (W. H. M.).—Excluding the most expensive. *Golden*: Mrs. Pollock, Sunset, Sophia Cusack, Lucy Grieve, Lady Cullum, and Mrs. Benyon. *Silver*: Italia Unita, Argus, Beauty of Guestwick, Imperatrice Eugénie, Burning Bush, Silver Star. *Bronze*: Beauty of Oulton, Bronze Queen, Mrs. Longfield, Canary Bird, Luna, Circlet; but instead of these, if not too expensive, select some of the newer varieties.

ROYAL HORTICULTURAL SOCIETY (*Constant Subscriber*).—If you write to Mr. Richards, Assistant Secretary, Royal Horticultural Society, South Kensington, he will send you full particulars of the steps needful for

becoming a Fellow. The Secretary, Royal Botanic Society, Regent's Park, will also give you the information you need.

DOUBLE POLYANTHUS (*Felton & Holiday*).—This is one of the finest double flowers we have seen. In former days we used to see a double nearly black Polyanthus. This variety displays the crimson and yellow colours of the ordinary single flowers, which makes it very attractive. It will, doubtless, make a very fine spring decorative plant. We had 6d. to pay for the carriage of your parcel.

NAMES OF PLANTS (B. M. H.).—*Spiraea barbata*, sometimes called *Hoteia japonica*. (F. M. L.).—1, *Corydalis lutea*; 2, *Aubrietia deltoidea*; 3, *Pulmonaria officinalis*; 4, *Dielytra formosa*; 5, *Saxifraga cespitosa*. (G. R. F.).—1, *Anemone apennina*; 2, *Draba aizoides*; 3, *Phlox subulata*; 4, *Saxifraga cespitosa*; 5, *Doronicum caucasicum*. (J. L. L. W.).—*Escallonia montevideense*. (W. C.).—*Fuchsia splendens*. (*Ada*).—Better specimen needed. (*Natal*).—*Amayllis* sp.; *Cereus flagelliformis*; *Dendrobium nobile*. (*Senec*).—We have no specimen of a climbing plant either with the above signature, or with your initials, "A. F." (*D.*).—We cannot as yet discover the names of the Pine and Oak; should we succeed we will state what they are next week.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending April 28th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

GAME FOWLS.

With reference to the two articles on Game fowls in your last Number, in which the name under which I write is mentioned, I reply as follows:—First, to Mr. H. Goodall, that if I were a Judge I suppose I should judge birds by much the same standard as the other Judges of Game fowls do, "by good shape and good feather." As to the exact shape of tails it is a matter of fancy, and breeders differ about it. I can only say that I much dislike the half-Malay-looking, large, drooping-tailed Game cocks and hens, "with their wings carried high up, half across their sterns like Geese, and the feathers of their tails all falling together on the lower feathers of the tail." I think such birds as these nearly half-bred Malays, and only fit for the spit or pot, as Mr. Goodall observes of the opposite style of birds. Mr. Goodall seems to forget that exhibition birds are rather of a different type from real fighting birds in many strains; and, I repeat, that the gamest birds are not our exhibition birds in general, but a smaller bird altogether, and that "a neat fanned," or "crest-fanned," spreading tail carried well up and not in the least broomy, is much the gamest form of tail, and shows none of the vile half-Malay type, and that a Game fowl should shield the fleshy part of his thighs with his wings, and not carry them on his stern as a Goose does.

Some of the boasted exhibition breeds and strains have been known to run away when tried with steel. Mr. Goodall's type of bird may be good birds, but are no better than those bred with the fanned tails carried well up. I am quite certain, in fact it is well known to almost all Game fanciers, that there are good birds with both forms of tail.

I have bred birds since 1831, when only eleven years of age, and never bred a cowardly cock once, and would warrant my birds to be gamier than any of the cowardly, great, coarse-boned, half-Malay type of Game fowls. The birds I consider perfection are in Brown Reds, Mr. Statter's, of Manchester (1); Mr. Fletcher's, of Manchester (2); and Mr. Aykroyd's, of Bradford (3); and in Black-breasted Reds, Mr. Brierley's, of Middleton (1); and Sir St. George Gore's strain (2). Such birds as these are fit both to fight and to exhibit, whatever form of tail they may present.

With regard to the article signed "CHALONER," I deny that anything erroneous has been advanced in any of my articles. I certainly was not aware that the cups at Birmingham were limited to stags, and consider it decidedly wrong to exclude the full-grown cocks from cups. I also confidently affirm, that the white-skinned birds have always possessed more courage and endurance, if well bred, than any of the "nasty yellow-skinned

exhibition things" we see at shows, which also put one in mind of the Malay type of Game fowls. I do not deny that good yellow-skinned Game fowls are often hotter in their nature than white-skinned birds are, but are never such keen birds, nor do they ever possess so much endurance as white-skinned Game do. As to the gipsy-faced birds, they are well known by most cockers to possess more endurance and hardness than any red-combed, red-faced birds ever do. I will back my own experience and judgment to the full against either "CHALONER," or Mr. Goodall, or Mr. Brown, of Perth, as I have made Game fowls one of my particular studies for many years of my life.—TREVOR DICKENS (NEWMARKET), *Markham Square, Chelsea*.

P.S.—Mr. Goodall makes an incorrect statement, when he says that I have advocated "droopings wings" for a Game cock, as I suppose it is well-known that a Game cock's wings can shield the upper part of his thighs without being either drooping or loose. I dislike drooping wings in a Game fowl, and they are only proper to Bantams. Mr. Goodall says he was "horried" to find two of his cocks that had broken out blinded and mangled. I do not think much of such slow birds as these. If they had been quick good birds they would have killed each other in a few minutes, instead of mangling one another.

I have never before heard of any good handler of Game cocks "using a stick or weapon of defence" to enter or open a pen with. Such a statement is absurd, and I would easily take the very fiercest Game cock out of his pen without any such nonsense, at the expense of a few blows from his beak on my hands, and have constantly done so with fiercer birds than Mr. Goodall has, perhaps, ever seen. Mr. Goodall can know but little about cockers' birds if he thinks that "exhibition birds" are the best specimens of "fighting Game cocks." Mr. Goodall's seem to be mere exhibition birds, and rather slow from his account.

I have also flatly to deny the statement made by "CHALONER," that my words formerly were that I could not see any beauty in any but Game fowls, for I stated in writing my admiration of Game Bantams, Bantams, Polish, and of several other breeds.

MERITS OF ANDALUSIAN OR BLUE MINORCA FOWLS.

HAVING kept poultry of various kinds for nearly fifty years, my experience may be useful to some of your readers.

Beginning with the common barn-door fowl, I afterwards kept Dorkings; but finding these too tender in rearing to be profitable, I tried some cross-breeds, the best of which I found to be that between Brahma Pootras and Dorkings.

After this I went rather extensively into the Cochins mania.

The Cochins, though good mothers, capital for sitting, eat too much, and lay too small eggs to be very profitable, besides the disadvantage of being inferior as chickens for the table. This objection also applies to the Dark Brahmans, which I next tried. Their being handsome and good exhibition birds is, in my opinion, their chief excellency.

Not being thoroughly satisfied with any of the above kinds for household and general purposes, I was induced, three years ago, to try the Andalusian, or Blue Minorca breed. Of these I cannot speak too highly; they are capital foragers, almost supporting themselves, excellent layers, their eggs being especially large and abundant, are very hardy, and though less frequently broody than other hens, are good sitters and mothers. They are first-rate birds for the table, being especially adapted for early spring chickens. I have taken considerable pains in selecting my stock, which is from Coles's breed, who was the original importer. To those, who, without being exactly poultry fanciers, keep a few fowls for domestic purposes, I can confidently recommend them.—EXPERIENCE.

THIS SEASON'S HATCHING.

I SEND you my experience in hatching this season.

On the 6th of March I put thirteen Dorking eggs under a Cochin hen, and on the 26th there were ten fine strong chicks hatched. One has since died, and two were unfortunately killed by a cat, leaving me seven, all healthy and very forward. On the 27th of March I purchased eleven eggs from a friend who keeps thoroughbred Partridge Cochins, and placed them under a Cochin pullet on the same day, and on the 18th inst. had again a brood of ten chickens, the handsomest and strongest I have ever seen. I expected these as in the previous case on the twentieth day of incubation, but no sign was visible of a chick making its appearance. I waited until the morning of the twenty-first day, but still only a chirp now and then could be heard inside the shell, no outward signs of life were visible. I then took away every egg and tapped them all round the larger end, until the shell was broken in two, and also cut the skin round the beak of the chick. I then replaced them under the hen for some hours longer, but no further progress was made. It was now high time I thought to get them out, which I did by first removing the shell of the larger end of the egg and then carefully tearing away the skin inside, and finally drawing each chick out of the last half of the shell. They seemed quite exhausted, but their animation was wonderful after they had been under the hen a little time.

It was now time to supply eggs to two more Cochin pullets, which I had in readiness for the result of this hatch, so I again visited my friend and procured all the eggs he had—viz., twenty, which I have placed under my two pullets, with two Spanish eggs added, to give them eleven each. But this time I have adopted a different plan in the arrangement of the nest, with a view to soften the shells and their inner lining. The nests are in boxes, perforated with large holes at the bottom; between this and the floor of the sitting compartment I have placed a turf which can be kept moist by moving the nest box off for a few minutes, and watering the turf. This will not disturb the hen or eggs.

It would be interesting to know how many eggs "Nemo's" friend placed under his ten hens, as I believe early hatches are often poor on account of too many eggs being placed under a hen. Eleven or at the most thirteen, are in my opinion quite as many as the largest hen can properly cover. When there are more, some are left partially uncovered at one time, and others at another, so that during twenty-one days it is very probable the whole of the eggs may have had a few hours cooling sufficient to destroy vitality.—GEORGE HASTLOW, 63, Albion Road, Dalston.

I FORWARD you my hatching results this season, as I think that I have no reason to complain.

February 27th, 7 hatched out of 13	March 15th, 10 hatched out of 13
March 4th, 9 " " 13	March 29th, 13 " " 15
March 12th, 10 " " 13	April 12th, 12 " " 15

—A. J. H.

HULL AND EAST RIDING SHOW.—The prizes are liberal, and are for Canaries, Rabbits, and Pigeons, as well as for the prime object—poultry. The names of the Judges, Mr. Hewitt and two others, are published, and as it is the day on which the testimonial to Mr. Hewitt is to be presented, we have no

doubt that the attendance will be very numerous. Entries close April 30th.

PACKING EGGS—HATCHING—BUCKWHEAT.

THERE is no question that our friend "Nemo" is correct in saying that packing should be tight. This is the essential, the next point being that the packing should be somewhat elastic. Attention being paid to these particulars, then moss, hay, bran, &c., will all do well. I have just received some Polands' eggs from Mr. H. Beldon, they were packed in oat husks; every egg is fertile. Pea husks I have also seen used.

Many of us, perhaps, err with early chickens in being too grasping, and placing thirteen or more eggs under a hen: this is often fatal to all. I am disposed to think that Cochin and Brahma eggs are less fertile than those of most other breeds; there are reasons for this, I fancy. In cold weather the eggs are not only more easily chilled while hatching, but are often ruined before they come to the nest, if the temperature be very low. It is notorious, probably in everything as well as our hobby, that if a thing is worth anything, the necessary trouble to get it is vastly greater than when the reverse is the case. The cottager's wife sits her hen on any eggs in any place, giving her any number of eggs. I have often heard of eighteen or twenty as a nest. Having given her hen a nest, and seeing that she has food, her clucking pet may do just as she pleases, but somehow the results are good, and very few eggs fail to hatch. I have known eighteen to hatch. We are, perhaps, extra careful, less grasping, &c., but success wholly eludes our efforts. Of course, the successful old dame says it is all our fault; still I personally feel better satisfied when I am certain that the hen is let out at stated intervals, that no egg is broken, and that the eggs are occasionally damped. It is, perhaps, more consolatory to fail after having done all you can to secure success; at least, I find it so.

I will also add my testimony to the value of buckwheat. The poultry like it, and as my experience goes, do very well on it. I wish I could obtain it more easily than I do.—Y. B. A. Z.

FROSTERLEY POULTRY SHOW.

The fourth annual Show of the Frosterley Poultry Society was held on April 11th, when the following prizes were awarded by the Judge, Mr. J. Simm, West Crumlington.

SPANISH (Black).—First, R. Pickering, Miln Houses. Second, R. Wall, East Layton.

SPANISH (Blue—Andalusians).—First, M. Reid, Bishopley. Second, C. Maddison, Frosterley.

DORKINGS.—First, J. Graham, Mac Neil. Second, Mrs. Sanderson, Bradley Hall.

COCHIN-CHINA.—Second, R. Wall.

GAME (Black-breasted and other Reds).—First, J. Dobson, Sunnyside. Second, Messrs. Emerson & Gardner, Hill End.

GAME (Duckwing Grey).—First, M. Frankling, Goose Croft. Second, D. Watson, Batts.

GAME COCKEREL.—First and Second, J. Fenwick, Stanhope.

GAME COCKS.—First, J. Graham, Mac Neil. Second, R. Wilkinson, Shillehouseside.

HAMBURGS (Golden-spangled).—First, R. Pickering, Miln Houses. Second, E. Pickering, Bishopley.

HAMBURGS (Silver-spangled).—First and Second, J. Taylor, Middle Bishopley.

HAMBURGS (Golden-pencilled).—First and Second, M. Ridley, Peak Field.

HAMBURGS (Silver-pencilled).—First, M. Armor, Frosterley. Second, J. Taylor, Middle Bishopley.

POLANDS.—First, C. Maddison, Frosterley. Second, Miss E. Johnson, Frosterley.

GAME BANTAMS (Black-breasted and other Reds).—First, M. Ridley, Peak Field. Second, W. Brown, Stanhope.

GAME BANTAMS (Any other variety).—First, S. Pennington, Low Biggins. Second, S. Maddison.

DUCKS (Aylesbury).—First, Mrs. Sanderson, Bradley Hall. Second, R. Pickering.

DUCKS (Any other variety).—First, W. Simpson, Fry Close. Second, W. & H. Thompson, Ferry Field.

DUCKS (Black Indian).—First, R. Pickering. Second, M. Reid, High Bishopley.

GANDER.—First, J. Dobson, Sunnyside. Second, M. Reid.

BIRMINGHAM SHOW.

A SPECIAL meeting of the Council was held on Thursday last, at the Queen's Hotel, the Earl of Bradford (President) in the chair, to make arrangements for the exhibition of the present year: which was fixed to commence on Saturday, November 28th, and to terminate on the Thursday following.

The Honorary Treasurer (Mr. Shackel) read a report, in which he expressed regret that the transactions of the last year showed a balance against the society of £178 13s. 10d.; but he added that a considerable amount (£150) had been spent in making additions to the working

stock. The reserve now stood at £560 3s. 1d.; and the balance due to the bankers on the current account was £225 7s. 6d., leaving a net balance in hand of £334 15s. 7d. The Society now possessed 2,700 poultry pens, 500 iron hurdles, and other movable stock to the value of at least £1,000. The cattle salesman had been dispensed with, by which they had been relieved of a considerable expense, without, as it was believed, inflicting any inconvenience upon exhibitors. On the motion of Mr. C. M. Caldecott, seconded by Mr. Councillor Lowe, the report and accounts were received and adopted, the latter gentleman suggesting the desirability of some statement showing the original cost and present value of their stock, in order that the Council might know their actual financial position.

Mr. Shackel also presented the following comparative statement of the admissions to the show, and the cash taken at the doors, since the year 1863:—

Year.	Admissions.	Cash at doors.
1863	61,530	£1,216 17 3
1864	62,533	1,334 4 4
1865	41,844	934 10 0
1866	21,511	648 3 0
1867	43,540	979 0 0

In reply to Mr. Luckcock, Mr. Shackel said that in 1865 the amount received in subscriptions was £1,175; in entrance fees, £176 10s.; in 1866, subscriptions, £1,468 10s.; entrance fees, £317; and in 1867, subscriptions, £1,558; entrance fees, £463.—(*Midland Counties Herald*.)

PARIS POULTRY EXHIBITION.

THE Acclimatisation Society of Paris has just held another poultry show, at which some of our English varieties were fairly represented, and a few notes may not be uninteresting. Of European reputation as an ornithological and practical establishment, the gardens of the Society in the Bois de Boulogne are too well known to need description, and it will suffice to say that they are the favourite resort of many thousands of Parisians, and nearly all the visitors to the capital. The space allotted to the poultry Show was near the conservatories. The pens were erected in three tiers, and placed back to back, all being covered with an awning, which did good duty against both wind and sun.

As a matter of course, the principal French breeds were more strongly represented than any others, although there was a large class of Cochins and Bantams.

First on the list were birds of La Fleche, and as a class they were thought so highly of by the Judges, that seven prizes were divided among them. In quality the class was excellent; but to pick out a pen to win, we think we could find one in England of imported birds that would run any in the Show very hard.

The Crève-Cœurs were numerous and excellent; they numbered more than thirty pens, and counted hardly an inferior one among them. In shape and symmetry some of the winning birds were remarkable, and they must have been very heavy. There were shown some of this year's chickens, strong, healthy, and well-developed; but as there was one class only for the breed, they, of course, stood no chance.

The uniformity of the type of the Crève-Cœurs spoke volumes, and formed a remarkable contrast to the Houdans, which were next to them. Three dozen pens presented a great variety of shades of colouring, shape of top-knot and comb, and colour of leg, but with hardly an exception every bird was five-toed. This breed appears now to be exactly in the same condition as that of the Crève-Cœur was some eight or ten years ago, before there was any demand for export. There is the breed, and some of the points are indispensable, but the others are left to the caprice of the amateur. There were not wanting at the Show many amateurs who appeared to understand the birds, who did not fail to say that the pure *poule de Houdan* should have no heard; the Judges thought otherwise. In comparison with the Crève-Cœurs, the average size of the hens at the Show would be about one-fourth less, and the difference in size between the cocks of the two breeds immensely in favour of the Crève-Cœurs.

The other French breeds demand little notice, and have nothing whatever to recommend by size or appearance. The breed *Le Maus* would pass either for Minorcas or Black Hamburgs, according to the choice for comb.

The much-vaulted *poule de la Bresse* has the appearance of being a decided mongrel. One breed, however, especially French, claims honourable exception, that of the Padones—White, Chamois, Herminés. In beauty, symmetry, and size of top-knot, they far distanced the Golden and Silver-spangled Polands with which they were associated, and were deservedly awarded a *prix d'honneur*. An English exhibitor, Mr. Beldon, had a second prize for a pen of Silver-spangled.

The Brahma Pootras are favourites; but the French idiosyncrasies are very much the reverse of ours. With the exception of one pen, all the birds exhibited were enormously vulture-hooked, all single-combed, and birds of the Light variety, but with more colouring than we should allow them. As regards the vulture hook, the same remark applies to the Cochins, all the French birds competing possessing it in a remarkable degree. There were some excellent Blacks, unusually large Cuckoos, indifferent Whites, and twenty pens of Buifs, in which size was the principal quality.

The competition in Dorkings was not great; Messrs. Bailly, of

London, took both prizes. Spanish fowls never were favourites in France, and show no signs of progress in public estimation. The four varieties of Hamburgs were represented well as regards quality, and some of the birds would have stood their ground fairly in English competition. The prizes were taken by Messrs. Beldon, Bailly, and Pickles, of the English exhibitors, and Mr. Boquet, of Paris. The Black Polish were few in number and low in quality. The Sebright Bantams mustered sixteen pens, and the first prize for Silver went to the largest birds, one of the hens having a single comb. The Game Bantams were few; Mr. Ledger was first, Mr. Boquet second. The little Japanese Bantams seem to be favourites in France, and were much admired. The Black, White, and Cuckoo Bantams call for no special remark. The wild Turkeys were of unusual excellence; the Black, White, and Grey inferior.

In the class for Pheasants were Kaleege, Chinese, common, and Versicolor, and two curious cross-bred birds. The Ducks and Geese call for no special notice; they were poorly represented in every way, and, with the exception of one or two good Rouen Drakes, showed very little quality. A pair of Curassows and a pair of little Bustards deservedly attracted much attention.

The exhibition of Pigeons, with the exception of one or two varieties, was not good. There were some excellent Runts; but the first prize was given to a very inferior pair of Blacks, to the prejudice of good Blues and Silvers. This was the only variety represented in any numbers. The Rabbits are always favourites in France. In the variety "Belier," one exhibitor had it all his own way, and sold all his Rabbits at very high prices. The Silver-Greys and Himalayans were good, and the Angoras pretty. The arrangements of the Administration, and the care and attention bestowed on the birds, reflected the highest credit on Monsieur de St. Hilaire and his assistants, and entitle them to the warm thanks of all the exhibitors.

A GUIDE TO CANARY-BREEDING.—No. 5.

I MUST apologise to the readers of the Journal for to some extent repeating in my last article a portion of the previous one—a mistake which arose from my mislaying a sheet of my manuscript.

By this time the nest of birds which chipped a fortnight ago will be almost as large as their parents; and the hen will most likely be making preparations for a second family, paying less attention to the nestlings, and leaving them in a great measure to the care of the cock, who will be unceasing in his devotion to them, his entire time being taken up with alternate visits to the egg box, the green food, and the nest of clamorous gluttons, each trying its utmost to establish its claim to the right of being first fed—their uproarious proceedings sometimes driving him away from the edge of the nest, only to return shortly, nothing disconcerted, to parcel out to each his mess of pottage with scrupulous impartiality.

When the hen is observed to be restless and carrying about such building stuff as she can procure, another nest box and a supply of fresh material must be introduced. Care must now be exercised to prevent her plucking the young birds, a misdemeanour she is too frequently guilty of. Should this be the case (and when the plucking once begins it does not require long to metamorphose a well-fashioned bird into a "raw gobby," as we called unfledged nestlings in our birdsnesting days), remove the young ones at once to a nursery cage, which must be suspended against the wires in the front of the breeding cage, when the feeding operation will be carried on through the wires, being careful to make the spaces between them of such a width as will conveniently admit the head but not the shoulders of the birds.

A supply of soft food will encourage the young ones to pick for themselves; and as soon as they can accomplish this most desirable object transfer them to a large "flight" cage, and gradually wean them from soft food to hard seed, which they soon manage to crack. Each succeeding nest must undergo this weaning process previous to being put with the others in the flight, as it will not do to give them other than hard food then. Keep up a good supply of fresh green food, such as chickweed, groundsel, shepherd's purse, plantain, &c., and allow a free use of the bath. It is a good plan, when the hen begins to lay a second lot of eggs before the young birds in her first nest are very forward, to remove these with the cock into the flight. He will not fail to single out his own, and feed them assiduously, besides doing an occasional good turn where it may be required.

There are a few operations which have been overlooked in their proper place.

If a felt nest be used, it is often desirable to change it entirely as soon as the eggs are all chipped, as the red mites will have made their appearance in greater or less numbers under-

neath it and at the back of the tin. If they show in numbers change the nest every morning, simply turning the young birds from one to the other. As they grow and fill up the nest a No. 2 must be substituted, affording more room, and if there be four or five birds this must be followed by a No. 3. They feather better, and are in many respects more comfortable in the larger nest.

It will occasionally happen that a hen will refuse to feed her young, sitting very closely and "sweating" them. This unnatural conduct on the part of his spouse seems to distress the cock exceedingly. He will sit on the edge of the nest, apparently remonstrating with her, and using his most persuasive eloquence to induce her to allow him to perform the duty she neglects, looking round and round the nest, anxiously trying to discover if there be a little head peeping out from underneath the hen. Should he be fortunate enough to find one, with a gentle tap he reminds the half-starved thing of his willingness to give it a meal, and in an instant the little mouth is gaping wide to receive the choice morsels, which, after all, are only too frequently swallowed by the cruel mother, whose appeals he never refuses. There is no cure for this. It is the result of a diseased condition. By driving the hen from the nest at frequent intervals, and allowing the cock to feed them, the little things may now and then be kept alive till the hen is disposed to attend to them herself; but by far the better plan is to remove the neglected youngsters at once, and place them under a nurse. It is very important indeed to have a few hens, well-domesticated matrons, whose eggs you may not hesitate to sacrifice in favour of more valuable stock. Many a valuable nest is saved in this way, and I know nothing more trying to the patience than, after waiting for the chipping of a choice nest, to find them apparently better than your anticipations, and yet dying off one by one from sheer want. They may be assisted by hand, and are occasionally reared in this way, an unusual amount of sympathy being evinced towards the little unfortunates, receiving attentions which would at another time be thought tedious. Feed with yolk of hard-boiled egg, moistened with a little lukewarm water, given on the end of a quill, the rule being, little and often.—W. A. BLAKESTON.

THE HONEY BEES OF CEYLON.

I AM indebted to a gentleman engaged in the civil service at Point de Galle for the following very interesting paper from the pen of a native headman on the honey bees of Ceylon.

The first species described is probably identical, or nearly so, with the very diminutive and harmless *Apis florea*; the second and third I should imagine to be varieties of *Apis indica*, the two kinds found in one hive at the same time being, of course, drones and workers; whilst the fourth would seem to be the magnificent but bellicose *Apis dorsata*, an attack from which proved fatal to Mr. Boddington, the unfortunate English engineer who jumped into the river Nerudda, and was drowned in endeavouring to escape from his enraged assailants. It was, I believe, a swarm of these bees which put the late lamented Lord Clyde and his entire staff to the most ignominious rout, and thus inflicted the only defeat which that gallant officer sustained during his final campaign against the Indian mutineers. Another remarkable instance of their ferocity was related in page 56 of our Journal; and I am informed by Mr. F. Smith, of the British Museum, that Dr. Jerdan states that he has lost a valuable dog through an attack by these insects, and that fatal accidents from the same cause are not unknown among the natives.—A DEVONSHIRE BEE-KEEPER.

REMARKS BY JAMES DE SILVA, MOHANDUM, OF HINDEDOOM PALTOO, IN THE SOUTHERN PROVINCE.

In Ceylon there are four varieties of the bee kind yielding honey.

1. *The Canemerya Masso*.—These resemble the common house flies, but are smaller. Hives are always formed in hollows of trees, with an outer covering for the protection of combs, which produce very little honey. It is of an agreeable odour, tasting very sweet. Besides the honey there is an eatable substance of a yellow colour, called *hackeroo* (jaggery), in taste resembling a mixture of sugar, flour, and an acid, which is glutinous, and not very agreeable. When a hive is molested this bee inflicts very little pain by the sting, but causes much annoyance by attempting to get into the ears.

2. *The Dandoowella Masso* (dies), resemble the bee, with an additional greenish streak lengthwise on the body. The hive

consists of a single round comb on some slender twig of a tree, and the honey is scarcely different from the bee honey.

3. *The Bee*.—Of this there are two varieties, the one of a brown colour and smaller than the other kind, with little honey; the other blackish and of larger size, with honey always in combs, though there is very little when out of season. Some, however, say there is only one species: the black colour and large size are to be ascribed to the bees being well fed, or they are the latest brood, which latter, I presume, to be correct, as both kinds are to be found in one hive at the same time.

When bees have remained for several years in one hive a species of winged insect, like a beetle, appears, which is a sure sign of the bees abandoning the hive.

Some people are very expert in finding out bee hives. They observe early in the morning a tree in blossom which bees frequent, and the uninterrupted arrival and departure of the bees guides the individual to the hive. I know an instance in which a man followed a hive of bees for two days (returning home in the evening), till he reached the hive.

In hives near the sea there is scarcely any honey, which, perhaps, arises from the want of substance to form honey, and the sting is more painful.

4. *The Bambaroo*.—This is about twice the size of an ordinary bee, and forms only one comb in the hive, which is to be found in some branch of the loftiest tree in the forest. As regards the colour of the body, the half near the sting is a deep black, the other half inclines to brown. The honey is thinner and more transparent than the bee honey, but not so sweet.

The mode of procuring it is to smoke the hive, when the mass rises to a great height in the air. During this short space of time, before the bees return, the party must be off, for if found they will be stung to death, and I know an instance where a party of six individuals was pursued more than a mile, and was obliged to dive under water, the Bambaras hovering all the while till they saw a head above water. Some of them are so tenacious, that although a hive should be burnt they will not quit it.

The quantity of honey found in the largest bee hive to my knowledge is one and a half gallon. In the Bambaroo I am unable to state the quantity, but it must be very considerable.

Bees form hives in vessels kept for the purpose, and no other kind would sit in an artificial place. The sting or point of the Bambaroo is so sharp that it would cut through the thickest cloth.

SUPER LEFT ON A HIVE.

Last summer I found the super on a hive to be but partially filled with honey. Thinking my bees might starve in the winter, I left it. Ought I now to remove it, or leave it? If I leave it, can I put another super at the proper time by the side of the other, instead of at the top, making a communication at the back?—T. T.

The super may now remain, but we doubt if the bees will take possession of another on the same level, unless direct communication be afforded with the stock hive.]

OUR LETTER BOX.

SELLING BOILED EGGS (*Cestrie*, and many others).—Our correspondents all complain in no measured terms that "J. L. L." has not published the name of the vendor; but there are many considerations requiring attention before such a course is adopted. "J. L. L." at all events, has put purchasers on their guard.

EGGS FERTILISED *Lemon Buff*.—Two days are sufficient if the cock takes to the hens.

APIARIAN SOCIETIES (N. M. C.).—We know of no such societies, and believe that none exists.

WOODEN HIVES SMELLING OF TURPENTINE (*J. Bryan*).—Expose the hives as much as possible to the sun and air before using them, but avoid dressing them with anything.

BUCKWHEAT AS A BEE FLOWER (*T. B.*).—There is no doubt that it yields a large harvest to bees. Germans are exhaustive on all subjects they examine, and one of them estimates that an acre of buckwheat yielded 14 lbs. of honey daily. Single hives gathered 3 lbs. on favourable days.

HEN CANARY WHIST SITTING (*C. A. J.*).—"I do not allow my hens the use of the bath while sitting, because I am of opinion that at such a time it is well to hold out as little inducement as possible to leave the nest. So far as regards any injury which might result to the eggs from the hen giving herself an occasional wetting, I should have little fear. I use open drinking vessels. I do not recommend them, but having a stock make use of them; and it will often happen, on replenishing the water, that a hen will wash as freely as she can through the water hole, and quite well enough to thoroughly saturate her breast, but I have never known any evil results to follow."—W. A. BLAKESTON.

From observations taken near London during the last forty-one years, the average day temperature of the week is 62°; and its night temperature 39.7°. The greatest heat was 82°, on the 7th, 1867; and the lowest cold 21°, on the 6th, 1855. The greatest fall of rain was 1.14 inch.

PEACH CORDONS.

THANKS to Mr. Rivers and to Mr. Fish, we have some reliable data as to the periods of blooming and the setting of the fruit in unheated orchard houses, whether span-roofed or lean-to.

The trees in our houses here were at their fullest bloom early in March—not by any means a very early date, especially after so mild a winter—and so they were about a fortnight in advance of those in the house at Luton, and in that at Sawbridgeworth. The first-mentioned is a lean-to, and the second is an elegant span-roofed house, glazed to the ground. Thus a lean-to at Luton is a fortnight later than a similar house in Guernsey, and a span-roofed house at Sawbridgeworth is about equal in point of blooming with a lean-to at Luton. This confirms our former experience that Guernsey is from eight to ten days earlier in Peach-ripening than Sawbridgeworth. We want further data respecting the blooming in other unheated orchard houses still further north, and some from the extreme south of England. We also need information as to the approximate limit of successful out-door cultivation of the Peach (any sort) northward of London, likewise how far beyond this limit a solid lean-to will enable Peaches to be ripened. For all these purposes of comparison there is in every way no fruit equal to the Peach. I do not think that these matters, so useful to the intending builder of orchard houses, are at all sufficiently established. Information can be had, and very excellent it is, nevertheless it cannot be so common as it might be, nor can it be final.

With respect to partially-heated orchard houses—that is, where fire heat is used only to keep out frost and to aid the setting of the fruit—it would be most interesting to know clearly how little would effect this in different localities.

An orchard house of the modern style, with abundance of cheap glass, filled with cordons of a hundred varieties of Peaches and Nectarines giving a length of season undreamt of formerly, and with rows of closely-pinched potted trees in the front, if it have a due or a row of pipes as an adjunct merely, is a very different matter from the forcing Peach house *par et simple*, as the French say. One great and distinctive feature of the orchard house of the present and of the future is the adoption of the cordon system of training in its several forms. Nothing can equal this style for simplicity and for productiveness. On these two important points even its detractors are agreed. Those who, like myself, have practised it for some fifteen years on the open wall and under glass care for nothing so much, but it is for trees in a good-sized orchard house that it is specially suited.

I have just finished the second thinning of my trees, and being unable to trust this delicate matter out of my own hands, it has been rather a toil in the heated atmosphere. How could this be left to others, when half a dozen large and established trees in full bearing were destroyed by the

violent application of tobacco smoke? So this fatiguing process of thinning was a personal matter. The bloom, as said previously, was profuse, and was at its maximum about the 1st of March, lasting, say, for three days in its fullest beauty. Certainly the rows of cordons on the wall, regularly defined, were very lovely. The large flowers of Rivers's Orange and Stanwick Nectarines were eminently attractive, while those of deeper hue, like the Honey Peach, were readily distinguished. Perhaps as beautiful as any was the large, very pale-petalled Noce Bianco, a new clingstone Nectarine of doubtful merit. An unnamed seedling Nectarine from Mr. Rivers was equally remarkable. The bloom in a large orchard house is always a sight.

Our Peaches rapidly set. By the middle of March each little fruit was clearly discernible. By the equinox the tender shoots were several inches long, and by the end of the month were crowding, but I never disbud.

As April went on thinning became necessary, and few matters in orchard-house culture are so important or so difficult. In the first place, as nothing exhausts the vitality of trees so much as profuse blooming, it is obvious that thinning this bloom would be a relief to the tree, but it is not always easy to decide, and should the weather prove unfavourable it would be perilous. We must, therefore, abandon the thinning of the bloom of Peaches to theorists. Better to wait a little longer, and commence soon after the setting. Even this is a very hazardous operation if done too early: the unskilled should wait a week longer, or till the fruit is as large as a bean. Then comes the trial of one's knowledge: we must weigh so many things. What crop did the tree bear last season? What is its age and vitality this season? What sort is it? What do we require for our own purposes? Nay, even what shall we impose on the tree to satisfy the unlimited demands of ignorant visitors? And so we should never commence till we have given a careful glance all over the tree. If we find all the best fruit crowded near to the summit we know that something is wrong with our culture, but we must, nevertheless, apportion this irregular crop according to some of the reasons just mentioned. A strong reluctance to thin at all seizes most of us at this moment: indeed, many succumb to its influence altogether.

My own diagonal cordons—of which readers of this Journal have often heard I fear, but they are most worthy of note just now—were in general regularly covered with fruit from top to bottom. Often a dozen finely-grown fruit clustered on each spur and its group of shoots, but as these are now like miniature trees in 5-inch pots this was not remarkable, only the whole tree could not bear such crops as one potted tree might. But what matters a potted tree? It is easily replaced, and may exhaust itself if needed, but not so these magnificent cordons destined to last for years. These have now reached the roof, and are at least 20 feet long, and as each alternate cordon is advanced 18 inches from the back wall, is about the same distance from its neighbour, and has shoots all round the lower part of the tree (which lowest shoots are kept very strong). One can easily see how such a cordon occupies an unusual

space, and that each is really as vigorous a tree as a moderate-sized fan-trained tree.

Commencing, then, from near the roof, I look down on hundreds of healthy young Peaches or Nectarines on each cordon. How absurd seem objections to this mode when such practical results are evident. Below me I see my spiral cordons, already 12 feet long in their twist, and having some 3 feet more to ascend. These are young, and this first season bear well; but further on is a row of fine pyramids two years plunged in the border. A great mistake! These are growing too strongly, and I can see even now will require very little thinning. This may be a hint to others. As long as these were in their pots they bore fairly, and were easily enough restrained; but now, left to themselves, they must soon become tedious to train.

Between my groups of spiral cordons are some very fine standards; these are really more manageable, but would soon become huge trees if left alone. I can see that all their extensions are "gross shoots," and, further, the shoots growing inwards below these are equally strong. As the fruit grows most on rather weak branches this tendency is objectionable, especially here; nor is the fruit on these, though very good, so numerous as on the cordons. These were really troublesome to thin; at last I used to rub them off without looking at them. As to the spiral groups they are very accessible. About two-thirds of the whole crop were removed at this first thinning; in a fortnight afterwards a second severe removal took place. Now all was easy, because many Peaches remained small, and were at once taken away. This difference in size is not accounted for by imperfect development alone. Here, for example, at one extremity of this house are two trees trained in the fan form—one an Elruge Nectarine and the other a River's Orange. Both are of the same size, both sorts naturally set equally well, but the tree which has now the most advanced fruit is that which has had the most watering. Thus I conclude that Peach trees require free supplies of water during this exhausting period, and it is just what Nature would give them, for, as I write, nearly 1 inch of water has fallen in the twenty-four hours, and it blows so hard that the mails are delayed.

I cannot resist adding a word more as to the progress of the spiral cordons also. Though these are several feet from the back wall, so much is gained by the twist that a length of fully 20 feet will be required before they reach the glass. As they are planted 16 inches apart in groups of five, and the shoots grow freely all round them, any one may estimate the proportion of heating space they occupy. In no other way—and this is important—in no other way can this be so well effected, taking into consideration quality, quantity, and variety of fruit. If this be really the case, then, who can doubt the ultimate universal adoption of the method in orchard houses? A cordon of this size when full grown can bear as freely as a moderately large wall tree, and if carefully thinned, need never have any rest such as potted trees require. These groups should alternate with standard or potted trees, so as to secure free access of sunshine to the lowest parts of the back wall in a lean-to. In a span-roofed house facing north-east and south-west (as such houses should face), this is of less importance.

I have sometimes alluded to the house of a friend and pupil, as he genially writes: could some who read this Journal see his 600-foot houses, all trained with diagonal cordons parallel with the houses, they would learn something new. After all, if we do spend so much time and money on these things, we may as well adopt the most advantageous plans, and this many well known in these pages have now decided on doing. Our poor pyramids are to be soon "disestablished."—T. C. BRÉHAUT.

BEDDING PLANTS

THAT MAY BE PLANTED OUT EARLY, AND OTHERS TO BE PLANTED LATE.

THE lesson taught us last year as regards planting out too early, is not likely to be forgotten by those who were sufferers; nevertheless, there are some plants so much harder than others, that they may be planted early without sustaining so much injury from cold as they would from other causes if kept in their present quarters. Such plants it would be advisable to plant out as early in May as possible, consistently with the state of the weather, the condition of the ground, and, more important than all, the condition of the plants themselves; therefore, where there is an opportunity, let no time be lost in planting them out, at the same time take care not to proceed far in adopting the same course with others which are

too tender yet to be trusted out of doors. A few notes on such plants as may be first removed to beds out of doors, as well as on those that had better remain in their sheltered quarters some time longer, may be useful at the present season.

Commencing, therefore, with such as will bear a tolerable amount of cold, the first on the list is one of the most popular plants of the parterre, and inapproachable, as yet, in one of the colours it represents—I mean the *Calceolaria*.

CALCEOLARIAS.—Assuming the plants to be in some cold pit, and not in pots, but growing in the pit, most likely if tolerably close together they will be drawing each other up, and running into flower, even if they have been partially thinned, as mine were, in the early part of March. At that time, in my case one half of the rows were taken out and planted elsewhere under shelter, but those that were left grew out and occupied all the space, and after April 20th commenced running into flower. Many of them I had removed into their permanent quarters before the end of the month, taking advantage of the dull, moist weather that occurred during the interval to perform the operation. Those which were transplanted I need hardly say were not so forward, and, consequently, not in such need of immediate removal; and if there had been an opportunity to transplant the whole, they would, of course, have been later, but it not being convenient to do so, and as *Calceolarias* have on former occasions done pretty well when planted early, the trouble of an intermediate transplantation was avoided. Of course, those who have the means and accommodation to give their plants more room, need not plant so soon, and may possibly benefit by the delay; or where *Calceolarias* form a portion of a bed, along with other plants which cannot be planted out so soon, in that case delay must take place; but when practicable, and where the plants have been well inured to the open air beforehand, they may often be planted out much earlier than they are with advantage.

GAZANIA.—This is also a hardy plant compared with many, and I usually treat it the same as the *Calceolaria*. Cuttings put into a cold pit in the last week in September, make excellent plants, bushy and well rooted, by the end of April, and they may then be planted in their summer quarters. Usually the *Gazania* likes a rather dry situation, and looks well hanging over the sides of some raised bed or vase, the plant requiring a less amount of soil to grow in than some of the *Verbenas*, which it resembles in habit, but in no other particular. The *Gazania* is, however, not a hardy plant, and will not bear so much cold as the *Calceolaria* and *Nierembergia*, but it has the property of resisting damp, and transplants well.

CERASTIUM.—Perhaps this plant ought to have preceded the *Calceolaria*, as it is much hardier—in fact, is a hardy plant, and in a dry situation will withstand any ordinary amount of cold, but a wet winter is fatal to it, and in the spring of last year it was very scarce. Where, however, plants are at command, it is a good plan to make fresh plantations of it early in April, and as it is mostly used for edgings, it can often be put in its place without interfering with the planting of other subjects afterwards. Certainly it would be better to have the whole of it planted during April, as it will then have a good start, and show itself earlier in the season.

CINERARIA MARITIMA.—Unfortunately it is not always that good rooted cuttings of this *Cineraria* can be had early in the season, otherwise there is no reason why they should not be at once planted, but it would be better to wait until such cuttings were well rooted before planting. We have for some years put in cuttings a little before those of the *Calceolaria* in autumn, and they have made tolerably good plants, but not early ones, and it is not advisable to remove them until they are well rooted. We have occasionally taken up old plants, and by pulling them to pieces have sometimes met with nicely rooted offsets; but these, unfortunately, so persistently run to flower and seed, that they rarely look well, and seedling plants, though perfect paragons of health and compactness, are invariably of a bad dull green colour: so that after trying many modes of growing this plant, we have found out that autumn or early spring-struck cuttings are best, when allowed to root well before planting. It must be confessed they are not so early as could be desired, at the same time they are not so apt to run into flower as when made earlier, which is unfortunately too apt to be the case with this otherwise useful plant. Its hardiness is well established.

VERONICAS of the New Zealand shrubby race, especially the variegated, are popular plants, but are less hardy than the plant last named; the variegated one, however, will bear the ordinary treatment of *Calceolarias*, and may be planted out at

the same time. It has the merit of being less liable to revert to the green condition than most variegated plants which I know, is not easily affected by disease, and is otherwise a useful ornamental plant. When it is also considered that no pots are wanted for it at any time, its utility to those whose accommodation for tender plants is limited is very great. It will do planted out at the end of April.

GOLDEN SAGE.—This deserves to be more generally grown than it is, for it is not very particular in respect to soil and situation, but the more it is exposed to sun the better it is in colour. The plant is as hardy as the common Sage, but it should not remain longer than two years, otherwise it becomes unwieldy, and, perhaps, some of it may die off. It makes an excellent edging around shrubs, and is in many respects a plant deserving of attention. Its liability to flower is not so great a drawback to it as to the *Cineraria maritima*, or *Centaurea gymnocarpa*, and it looks well during the winter, but is not so yellow as when the growth is in a younger condition.

DACTYLIS GLOMERATA.—This Grass, though hardy, is somewhat liable to die off during the winter, so that I have on more than one occasion all but lost it. In soils which are suitable it may be planted by the end of April, provided, as stated for other plants, it be fit to plant out at the time. When in good condition this plant looks well, and it is certainly not so much grown as it ought to be.

To the plants above adverted to others may be added. Cupheas are tolerably hardy, but I do not know that any advantage arises from planting them soon, and I hardly know what to say about Petunias, for I have ceased to grow them to any extent excepting from seed, the established kinds from cuttings being so liable to die off. No advantage would, however, result from planting them early, and, therefore, it would not be prudent to include them in the list. Many other plants useful in the flower garden might be mentioned—as *Pyrethrum*, which may be planted at any time; *Lavender Cotton* the same; while *Viola cornuta* is best planted in the autumn, a better spring bloom following, and the same may be said of *Mimulus*, *Pentstemons*, and sundry other plants. Perhaps in no instance are the advantages of autumn planting more apparent than in that of *Viola cornuta*, which seems to be proof alike to cold, the attacks of slugs, and the other mishaps that winter plants have to encounter, as it is seldom a plant is lost, and it commences to flower much earlier by being established so long before the flowering time.—J. ROBINSON.

(To be continued.)

RAISING VINES FROM SEED.

HAVE any of your readers ever attempted to cross Vines? If they have they will agree with me that a more tiresome, tedious operation is not often performed. To tie a midge fit to tempt a Derbyshire trout requires patience and manual dexterity, but it can be tied in a cool room and when you are in the humour; but to cross Vines successfully you must wait in a lighthouse till they choose to open their flowers, and remove each anther separately with a fine-pointed pair of scissors without the least shaking, you must select pollen from another flower and apply it to the minute stigma, and if, tired of looking at such minute objects, or oppressed by the heat, you take a walk for half an hour, you will, perhaps, find a score of flowers have opened in your absence. If these are examined with a good glass they will generally be found covered with pollen, and as I wish to be as sure as possible that the seed sown is really the result of a cross, I should cut them all out and wait for more. "As sure as possible." Well, I believe we never can be quite sure. When every care has been taken, and I believe my hands are as steady and my eyes as good as those of most persons, still a strong glass generally shows a few grains of pollen scattered on the style, if not on the stigma. If to prevent this you remove the cap from the bloom before it opens of itself, you only increase the evil, for then the pollen is sure to be distributed. Having done one's best to prevent the stigma being fertilised by its own pollen, we must trust, if any has fallen upon it, that that which is applied from a foreign source will be more efficacious.

Some persons will say, But why raise seedling Vines? Have we not already plenty of good kinds? Are not a great many of the new ones worse than the good old varieties? No doubt, and some are very valuable additions. I certainly am not amongst the number of those who despair of great improvement in Grapes. Why should we not try to add to the good

qualities they already possess that of scent? It has always struck me that if Pines had no scent they would not rank so high in public estimation as they do now. If Grapes, in addition to their beauty and flavour, possessed a fine bouquet, would it not be an improvement? This is what I have been trying at for some years, and I will tell how the idea came into my mind. Meeting with the rest of the Fruit Committee at Chiswick some years ago, we entered a house of young Vines in pots. The moment we entered there was a strong smell of ripe Strawberries, and I exclaimed, Why here is the old Hautbois Strawberry which I have not seen for years! Dr. Hogg laughed and said, "It has the exact smell of that Strawberry, but it is a Grape." Never having heard of the Strawberry Grape, or of any kind of Vine with scented fruit, I was very anxious to taste it, but like almost all the members of the Committee, spat it out immediately—the strong perfumed flavour was to me most disgusting. To my surprise one gentleman said, "I do not agree with you, I like it."

Whilst tasting the other varieties the following train of thought passed through my mind:—What a pity a Grape with such a fine scent should be so nasty. After all some one likes it. Is it not because the flavour is in excess? Who can eat a Williams's Bon Chrétien Pear which has ripened on the tree? Yet the same Pear gathered before the flavour is too much developed is first-rate. Fusel oil is, perhaps, the most disgusting thing in nature, but an infinitesimal drop in a large quantity of barley sugar gives the flavour of the Jargonelle Pear. Who does not like the smell of a good ripe Apple? but few would choose to live with a bushel of Ribston Pippins in their drawing-rooms. Why should I not try to modify this flavour by crossing with our best Grapes? Besides, it is said the American Grapes are proof against the attacks of mildew; perhaps the cross may possess the vigour of constitution.

Influenced by these reasons I procured some cuttings, grew them, flowered them, and crossed the flowers with our best Grapes. Seedlings from these crosses are now fruiting. I do not know if they will be of any value, but they are most interesting. I think never before were such leaves seen on a Grape Vine. One, a cross with Muscat Hamburg, has leaves more deeply cut than that variety, and almost twice the size. Some have deep red stalks and leaves of the darkest possible green, and of large size, whilst others might have descended from the Parsley Vine. One has not only set its fruit, but the fruit is already stoned, whilst a Black Hamburg next to it and nearer the boiler is only just coming into flower. The few showing fruit appear rather small in the bunch, so I have crossed them again with the largest Grapes known, such as Canon Hall Muscat, Alicante, &c. What do you think of my chance of raising a good Grape?

Of one fact I am certain, few persons know the amount of trouble, expense, and anxiety represented by one good thing in the way of fruit; the prizes are much talked about, the countless failures are known only to the disappointed ones. I have now scores of Peach and Nectarine trees showing fruit for the first time; numbers of seedling Vines, a few of which will fruit this season; lots of seedling Rhododendrons, and about six thousand seedling Pelargoniums, so you see I am trying to leave my mark.—J. R. PEARSON, *Chilwell*.

MOVEMENTS OF THE COLOCASIA ESCULENTA.—In a paper, addressed to the Academy of Sciences, M. H. Lecoq mentions as an instance of movement in plants the *Colocasia esculenta*. In visiting his hothouse in January last, he perceived a motion in one of the leaves of this plant; he at first attributed it to a draught, but upon examination remarked the same motion in the four other leaves, there being no more at the time. It was a sort of rhythmical tremor, so long as to affect the plants that stood near. His attention being thus aroused, he continued his observations daily, and found the motions of the *Colocasia* were not regularly periodical. Sometimes its tremor would last the whole day and following night; it usually occurred from nine in the morning until noon, and not infrequently the plant would remain in a state of perfect rest for days, and even whole weeks. This induced M. Lecoq to attach a few light bells to the plant, in order to be warned of the approach of the paroxysm. On one occasion it began at two o'clock after midnight, and continued nearly the whole morning. The bells tinkled, and the leaves of the *Colocasia* struck the neighbouring plants with sufficient distinctness to enable the author to count

the pulsations by a stop watch; he found them to be between 100 and 120 per minute. On several other occasions the fits were exceedingly violent. On the 2nd of March last, although the temperature of the hothouse had fallen to 7° Cent., the plant seemed to be labouring under a fit of ague, so that the very pot containing the plant, and weighing about 22 lbs., shook so that the hand of a man could not steady it. The rhythmical tremor was likewise communicated to a fine leaf of a *Strelitzia Nicolai*, another of a *Philodendron pertusum*, and to some fine clusters of flowers of the *Begonia manicata*. M. Lecoq cannot explain the cause of this tremor, but he thinks himself warranted in not attributing it by any means to the temperature; he suggests the possibility of its being the result of a stoppage in the regular perspiration of the plant.

ROYAL HORTICULTURAL SOCIETY.

MAY 5TH.

FRUIT COMMITTEE.—Messrs. J. C. Wheeler & Sons, Gloucester, exhibited some very finely-kept examples of Ashmead's Kernel Apple; they were exceedingly fresh, rich, and juicy, and were unanimously awarded a special certificate. Mr. Gardiner, gardener to Sir George Phillips, Bart., Weston House, Shipstone-on-Stour, sent a dish of Royal George Peaches; they were quite ripe, of fair size, but not particularly rich in flavour.

Mr. E. Baxter, gardener to Charles Keiser, Esq., Broxbourne, Herts, exhibited a Cucumber named Broxbourne Rival, which the Committee considered to be inferior, although very similar, to Telegraph. Mr. H. Drover, gardener to H. Clark, Esq., Fareham, Hants, exhibited a brace of Cucumbers named Drover's Telegraph, but the variety was of no particular merit. Mr. Woodward, The Gardens, Garbrand Hall, Ewell, Surrey, exhibited some examples of Cattell's Eclipse Broccoli, which were very inferior.

James Bateman, Esq., Biddulph Grange, Congleton, exhibited some preserved fruits of the Chinese Loquat (*Eriobotrya japonica*). The preserve was sweet and pleasant, but with no particular flavour. Mr. J. Carr, gardener to P. L. Hinds, Esq., The Lodge, Byfleet, Surrey, exhibited some ripe fruit of *Eugenia jambos*, the Rose Apple, from a seedling tree about four years old grown at Byfleet, where so many of our fine tropical fruits have been brought to such perfection. The fruit is handsome in appearance, about the size of a Washington Plum, of a pale straw yellow colour; the flesh rather dry, about a quarter of an inch in thickness, hollow, enclosing two large seeds; flavour peculiarly pleasant, partaking of that of the Muscat Grape and the Damask Rose, with a scent resembling that of the Myrtle. The plant has borne about ten dozen of fruit, and as this is the first time of its having been fruited and exhibited in this country, it was unanimously awarded a special certificate.

FLORAL COMMITTEE.—One of the best exhibitions ever seen at a Tuesday meeting was brought together on this occasion; there was a rich supply of valuable plants from the metropolitan exhibitors, and the awards made for novelties were very numerous.

Mr. Moore, gardener to the Earl of Shrewsbury, received a special certificate for a small collection of cut Orchids. Messrs. Veitch exhibited young plants of the Society's hybrid *Coleus*, which have not been in their possession more than a fortnight—viz., *C. Bausei*, *C. Saundersii*, *C. Berkeleyi*, *C. Batemanii*, and *C. Ruckeri*, each of which was justly honoured with a first-class certificate. *Aphelandra chrysopa*, with bright yellow flowers, from the same firm, had a first-class certificate, also *Scutellaria mocciniiana*, a handsome greenhouse plant with bright scarlet flowers. *Begonia Huttoni* had a second-class certificate; it has pale buff flowers with finely-cut foliage. *Primula cortusoides striata*, a seedling from *Primula cortusoides*, having a white stripe in the centre, received a first-class certificate; *Cymbidium Huttoni*, a dusky, dingy-spotted Orchid, had beautifully marked, a second-class certificate; *Oncidium cucullatum*, a small spotted kind, a first-class certificate; *Burlingtonia fragrans major*, resembling *candida*, a first-class certificate; *Epidendrum pauciflorum*, with an elegant spike of rosy purple narrow-petalled flowers of promising character, a first-class certificate; and *Laelia grandis*, a curious buff-winged variety, a second-class certificate. A special certificate was awarded Messrs. Veitch for the collection of Orchids, one for a collection of *Amaryllids*, and another special certificate for miscellaneous plants.

Mr. Turner, Slough, sent a fine collection of Tulips, and received a special certificate; also a small collection of beautiful *Auriculas*, selfs and show flowers, for which he likewise was awarded a special certificate. He also received first-class certificates for three seedling *Auriculas*—viz., Mrs. Mendall, a fine grey-edged flower; Novelty, a purplish violet self; and Wonderful, self, a large deep reddish-maroon. Mr. Turner's *Auriculas* have been the admiration of all who delight in these spring flowers; it is to be regretted that the season at which they are in perfection is so uncertain. Last year they were only at their prime in May; this year they were in perfection in April. How absurd it is to find fault as to the time fixed for exhibition, for so one can foresee what the season may prove. It is a flower to be exhibited only when the season permits, early or later in the spring.

Mr. Noble, Sunningdale, sent a large collection of seedling *Clematises*, four of which were selected as superior varieties, but none of them being named, the Committee could not deal with them. If exhibitors would but consider how much the Committee have to do, and in what a short time it is expected to be done, they would not think of requesting names to be assigned by them. Every florist's flower or hybrid garden flower must be named to be recognised. There were decidedly first-class flowers in this collection. Mr. Williams, Paradise Nursery, sent a specimen of a curious *Nidularium*, called *atrosanguineum*, which was awarded a first-class certificate; *Cocos Weddelliana*, an elegant plant, and graceful for table decoration in its young state—first-class certificate; and *Maxillaria lutea alba*—second-class. A special certificate was awarded for Mr. Williams's fine collection of plants. Messrs. Smith, Dulwich, received special certificates for a collection of plants, consisting of fine specimens of *Erica vittata* and seedling *Azaleas*. *Azalea* Sir Robert Napier was awarded a first-class certificate. The colour is a deep fiery red, distinct from that of any known variety, but the flower was rather too rough in the outline, and small. The plant, however, was out of condition. This seedling will prove a general favourite for its distinct colour. Messrs. Smith also exhibited a pale rose, smooth-petalled, seedling *Azalea*, called Oracle, but too small for exhibition purposes.

Mr. Baxter, gardener to C. Keiser, Esq., Broxbourne, sent two exquisitely grown specimens of *Dendrobium pulchellum*, which was awarded a special certificate. Mr. Wimsatt, Ashburnham Park Nursery, received a first-class certificate for another of the Society's hybrid *Coleuses*—*C. Marshallii*, also a second-class certificate for *Coleus Telfordii* anrens, having pale yellow foliage, with small dark crimson markings in the centre.

Messrs. E. G. Henderson, Wellington Nurseries, exhibited a small but good collection of Orchids, which was awarded a special certificate. Mr. Woodward, Ewell, sent a very beautiful specimen of *Trichopilia suavis*, which received a second-class certificate; and Messrs. Lee, Hammersmith, had a special certificate for a collection of plants, containing many well-grown and ornamental specimens. Mr. Pilcher, gardener to S. Rucker, Esq., had a second-class certificate for *Epidendrum inversum*, an old and neglected Orchid with a peculiarly fine scent. Mr. Hooper, Bath, gained the Silver Floramedal for twenty-four Pansies, a special certificate for Pansies in pots, and showed several promising seedlings, but not in good condition. Mr. Hooper also sent a seedling Pink adapted for forcing, and a variegated Pansy, which will be useless as a variegated plant. The seedling Pansies noticed were Mr. Turner, Mr. Bull, and Cheerfulness, a white bedding variety. Mr. J. Jackson, Kidderminster, sent cut specimens of a double *Polyanthus*; the same variety has been sent from three other firms, and it would therefore seem to be widely distributed. Mr. Brown, Slough, and Mr. Shenton, Biggleswade, exhibited cut Pansies.

A collection of Mr. Bause's seedling *Caladiums* was sent from Chiswick, and they were beautiful from the delicacy of the tints which they exhibited, the ground colour being pale yellow. By some great inadvertency these plants escaped notice. They are of great merit, and will take a position in due time.

Mr. J. Hodge, gardener to E. Wright, Esq., Gravelly Hill, Birmingham, sent cut specimens of Orchids, but not of the best varieties; Mr. Wimsatt, Ashburnham Park Nursery, fine specimens of Bronze Zonal *Pelargoniums*, *Rosalina*, *Her Majesty*, *Admiration*, *Empress Eugenie*; and Messrs. E. G. Henderson, seedling Variegated Zonal *Pelargoniums*, *Maid of Judah*, *Star of Peace*, Mrs. Gladstone, Mary Hadwin, Mrs. Grieve, and E. G. Henderson, a Bronze Zonal. Mr. Tanton, Epsom, contributed a variety of *Leschenaultia biloba*, *Polygala Dalmaisiana*, *Aphelaxis macrantha splendida*, and *Boronia serrulata compacta*. C. Leach, Esq., sent cut specimens of *Elisena longiflora*, rarely seen in flower, and *Laelia praestans*. From Mr. Rae, Eglinton Castle, came four *Cinerarias*; from Messrs. Rollisson, *Vanda tricolor meleagris*, and *Gymnogramma Rollissonii*; and from Mr. Nelson, Bristol, a seedling *Lomaria*, supposed to be a hybrid between *L. gibba* and *Blechnum corcovadeense*, the same variety as that exhibited by Mr. Dean at the last meeting.

SCIENTIFIC COMMITTEE.—The second meeting of this Committee of the Royal Horticultural Society, was held in the Council Room at half-past one, W. Wilson Saunders, Esq., F.R.S., in the chair. The following members were present:—Dr. Thomson, The Rev. J. Dix, Mr. Marshall, Mr. Reeves, Dr. J. H. Gilbert, Dr. Masters, Mr. Moore, Mr. Bateman, Mr. Blenkins, Mr. Mumby, Dr. Welwitsch, Dr. Voelcker, Mr. A. Murray, Mr. J. Miers, Mr. Wilson, and the Secretary, the Rev. M. J. Berkeley.

Mr. Masters made a communication to the Committee on the hair-like cells he had discovered at the base of the flower of *Aucuba japonica*, which would entrap the pollen cells, and he considered them as performing an important office in the fertilisation of the plant. The epidermal tissue terminating in these hair-like processes he had found to exist in both sexes.

The Rev. M. J. Berkeley exhibited a portion of the stem of a Scotch Fir infested by an insect, to which the death of the tree was attributed. The Committee was in doubt whether this was a sufficient cause for the decay of the tree, and it was referred back to the gardener who had sent it for further information.

Two communications were read by the Secretary, on the subject of the black spots on Orchids. One was from Mr. Earley, who considered there

to be caused by an excess of moisture combined with an insufficiency of light and air. The other paper on the same subject was from Mr. James Hosack.

Mr. Berkeley showed some specimens of Orchid leaves from Mr. Anderson, on which he considered three distinct forms of spots could be detected, the chlorotic spots, the black spots, and the putrid spots. Mr. Marshall brought under the notice of the Committee a number of leaves taken from various species of Orchids, and in which nearly every form of this disease was visible: he considered this result to be dependant on the plants getting a sudden check when they were in full growth, as several specimens which were sent to the International Horticultural Exhibition in perfect health became affected, and never recovered from the effects. Mr. Hilenkins stated that he had examined the leaves from three species of Orchids—viz., *Vanda gigantea*, *Dendrobium maculatum*, and a species of *Oncidium* which he laid before the Committee, and which had been sent to him for microscopical investigation. In two of the specimens he did not consider the appearance was fairly to be attributed to this disease, but it seemed to him to be more like the erosion of a species of thrips or other insect. He found the cells of the leaf-tissue blackened as from decay, but in the *Vanda*, which was acknowledged by the Committee to be affected by the disease, he detected even there an enlarged and discoloured nucleus of the cell, and the reniform cells forming the margins of the stomates seemed to be particularly affected. He suggested it would be advisable to appoint a sub-committee who should visit the houses of the principal Orchid-growers for the purpose of acquainting themselves with the different forms of that disease and the conditions under which they occurred, and report the result of their inquiries to the general Committee. Mr. Wilson Saunders approved of the appointment of a sub-committee. Mr. Berkeley informed the meeting that it was the putrescent form of that disease that affected Mr. Rucker's plants. Mr. Bateman had some plants in which the disease resembled the action of thrips. He thought one fact was determined—that there were various causes for this disease. Mr. Marshall stated distinctly that he had removed thrips from the leaves of Orchids so affected. Mr. W. Saunders was of opinion that a sub-committee would be of great advantage to visit different houses, and thoroughly examine into the question. Mr. Bateman thought the sub-committee might make it a part of their labours to ascertain whether the disease was contagious or not.

Ultimately a sub-committee was appointed, and the following gentlemen were nominated members:—Dr. T. Thomson, Mr. Marshall, Dr. Masters, Mr. A. Murray, Mr. Bleukins, and the Secretary.

At the next Meeting "The Nomenclature of Plants" will be brought under the consideration of the Committee.

GENERAL MEETING.—W. Wilson Saunders, Esq., F.R.S., in the chair. After a list of donations had been read, fourteen new Fellows elected, and the Daventry Floral Society admitted into union, the awards of the Committees were reported, and in doing so the Rev. J. Dix directed attention to a cheap wooden tally which, having a square end section, admits of four names being written on the four sides. The opposite extremity, that intended for insertion in the soil, is formed into a wedge by one diagonal cut, dividing each tally from the other made out of the same bar of wood, and is coated with anti-corrosion paint.

The Rev. M. J. Berkeley then observed that at the last meeting he had called attention to a form of *Gesneria* which exactly corresponds with *Gesneria macrantha purpurea*, figured in the "Gardeners' Magazine of Botany;" and Mr. Tanton, who sent it, had since informed him that the bulb had been collected in New Grenada, and had brought to the Meeting a cutting in flower; but though the plant exhibited on the former occasion exactly accorded with the figure in the work referred to, the cutting differed in the flower being of a lighter crimson, and in the colour and pubescence of the calyx—differences, however, which might be ascribed to its having been subjected to forcing. The only difference between it and the true *macrantha* from Messrs. Veitch was a spot on the lip of the one, which was absent in the other.

Mr. Berkeley then directed attention to two Tulip flowers, produced by plants raised in his own garden from seed, which had been sent him fifteen years ago, or more, by Dr. Selwitsch, from Portugal. Until last year all the flowers were rather dull in colour, with a dark blotch at the base of each petal, then one of them "broke," but he lost the bulb; this year, however, a great proportion of the flowers had done so, the dark blotch had vanished, and had given place to a scarlet feather, a number of the scarlet cells had changed into yellow, and this colour shining through the scarlet rendered the latter more vivid. As a fact bearing on the cause of "breaking," as it is termed by florists, he would mention that the bulbs last year, instead of being planted in November as usual, had been kept out of the ground till January.

Mr. Berkeley passing to the subject of edible Fungi, remarked that a dish of *Agaricus gambosus*, or St. George's Mushroom, had been shown, although the specimens were very far from being of so large a size as that species was known to attain. This was one of the best of the edible *Agarics*, differed from the common Mushroom in having white gills, and was commonly to be found in grass fields about the 20th of April, coming up after rain. This year it did not appear till after the heavy rains of last week. It was nearly allied to the *Monoceron*, much esteemed by the French, and which they preserve for

winter use. After referring to a passage in a letter from Dr. Livingstone to Sir Roderick Murchison as to the value of Fungi as food, Mr. Berkeley said he had just received a letter from Professor Fries, one of the greatest authorities on the subject, who had sent him a prospectus of a new work on Hymenomyces, a class of Fungi which afford excellent nourishment. In Sweden and Norway they were used along with flour in bread, and must certainly be better than the inner bark of trees, which was used there for the same purpose. In connection with this, Mr. Berkeley observed that at the time the Potato disease broke out Silesian Beet had been recommended for mixing with flour for bread, and it answered the purpose very well, only the bread made with it contained little lines of treacle, which were produced in the process of panification. As an article of food he hoped the Mushroom tribe would not be so much neglected as it had been. After stating that four dishes of Mushrooms—two from natural and two from artificial spawn—sent by Mr. W. Ingram, of Belvoir Castle Gardens, exhibited hardly any difference, Mr. Berkeley added that he had received a letter from Mr. Harry Chester, of which the purport was a hope that the Royal Horticultural Society would take up the subject of Fungi as food, and get analyses of them; and Mr. Berkeley said that in addition to the prize which had been already offered by a friend for edible Funguses in September, a second prize would be given by another party; and it might therefore be hoped that there would then be an excellent display, not only of esculent but of poisonous Fungi.

A Fungus belonging really to the genus *Uredo*, to which a great many Fungi had been improperly referred by botanists, was then noticed, and a drawing of it exhibited, in which it was seen to form little bushes consisting of vertical cells with mycelium below.

Mr. Berkeley next referred to *Scilla campanulata*, of which a specimen double the size he had ever seen before was sent by Mr. Cox, of Redleaf, who informed him that the causes of its presenting such an unusual degree of development appeared to be its being grown in very rich loam, and the roots never having been disturbed. An *Anopterus* exhibited was then said to remind one very much of a *Clethra*, and to be nearly allied to *Escallonia glandulosa*; and in conclusion Mr. Berkeley pointed out a case in which *Auricula* stamens had become developed into leaves and the ovules were entirely naked. Attempts had been made to raise plants from the latter, but had entirely failed.

Mr. Bateman said, that before offering his promised remarks on the Loquat, he would call attention to some very beautiful Clematises raised by Mr. Noble of Sunningdale, but which were unnamed; also, to two remarkable species of Gum trees (*Eucalyptus*), from the beautiful gardens of C. J. Woodfield, Esq., at Camus, on the shores of the Mediterranean, where no trees seemed to have such a rapid growth, this amounting to 8 or 10 feet in a single year, and some of them were 50 or 60 feet high. Not only did they produce flowers but seeds as well, the fruit being like an acorn, but with this exception, that instead of the cup being at the bottom it is at the top of the fruit.

With regard to the Orchids shown, his (Mr. Bateman's) remarks would on this occasion be brief. The first he would refer to was a very pretty species of *Epidendrum* from Mr. Rucker, which, though it had neither been figured nor exhibited before, had been named *E. inversum* by Dr. Lindley many years ago. It possessed pretty rose tints, was agreeably fragrant, and being, moreover, a cool Orchid it would, no doubt, become a favourite. Next, there was the *Trichopilia suavis*, from Mr. Woodward, of Fwell, and which was, perhaps, the most perfect specimen of that plant shown at any meeting. In a nice collection from Messrs. E. G. Henderson, there was *Dendrobium infundibulum*, which now vindicated its character as being distinct from the *D. formosum* shown by Messrs. Veitch. It, too, was a cool Orchid, flowering beautifully with his friend, Mr. Wentworth Baller, under that mode of treatment. Attention was also drawn to a remarkable *Oncidium* from Mr. Salt, of Leeds, sent under the name of *O. concolor*, but of which the clear pale yellow flowers were certainly not those of the species commonly called by that name; to *Saccolabium ampullaceum*, from Messrs. Rollisson; and to cut spikes of an accidental variety of *Cattleya citrina*, exhibiting a rich orange tint instead of the ordinary lemon colour, and which was more beautiful than the common form. Turning next to Messrs. Veitch's collection, there were in it *Laelia grandis*, a fine kind of easy culture and having buff flowers; the Ceylon *Dendrobium MacCarthiae*, which had formed the subject of one of his lectures last year, and of which not a word too much had been said in its praise; but fine as Messrs. Veitch's specimen was on the present occasion, the plant in time would be found still more beautiful. As regards *Epidendrum paniculatum* from the same firm, it was still flowering weakly, but when stronger the spike would be something like a bunch of *Lolae*, only the flowers would be richer in colour. A pretty new white *Dendrobium* was shown by Mr. Williams, and it possessed the additional merit of being sweet-scented; and in a collection which should be nameless, there was a *Cypripedium*, called *biflorum*, which exemplified the folly of naming as distinct species plants in which accidental deviations from the normal state had taken place, for not a single stem was two-flowered. Dr. Lindley made a similar error by giving to an *Oncidium* the name of *uniflorum*, whereas the plant now never condescends to produce less than three blossoms on a spike. The last Orchid to which he would direct attention was *Dendrobium thyriflorum*, of which Mr. Marshall had brought a beautiful cut spike.

Mr. Bateman said he would now turn to the Loquat, the *Mespilus* or, more properly, *Eriobotrya japonica*, the *Néflier du Japon* of the French, and of which there was in the room a large specimen brought from the Society's conservatory. There was this difference between the Floral and Fruit Committees, that while the former had to deal with entirely new forms, the labours of the latter were much more monotonous, being chiefly confined to new varieties of old forms, although the present meeting was an exception. If we supposed a horticulturalist who died one hundred years ago to revisit us and accept an invitation to a breakfast at some pleasant suburban villa, almost everything would be new to him among the flowers in the conservatories and parterres, and among the shrubs and trees in the grounds. He would, therefore, probably expect equally delightful surprises among the fruits of which he would presently have to partake at his host's hospitable board, but in this he would be disappointed. There would be Peaches and Pine Apples, very fine of their kind; Grapes, and Figs, and Strawberries, and so forth, but of all these he would have partaken before. New fruits there would be absolutely none, unless his host happened to grow the Purple Granadilla or the Banana in his stoves; but these were quite exceptional cases. To be sure if he had visited Sion ten years ago, he might have tasted the Mangosteen, and if here to-day he might have indulged in *Eugenia jambos*, or the Rose Apple, but these opportunities, like angel's visits, were few and far between. Our own Queen, in whose reign it fruited, only tasted the Mangosteen once, whereas King Charles, to whom the first Pine Apples were presented, feasted upon them again and again. All this was very strange and disheartening. There were plenty of excellent tropical fruits, but nobody except Mr. Hullett has ever tasted them in this country. From time to time a tropical fruit was produced in the garden of some wealthy amateur, and after the fact had been duly proclaimed, it was half a century before we heard of it again. Thus we have had the Longean and Liteli, the Mango, the Blimbing, &c., and then the Loquat, to which he would at present confine his remarks.

The Loquat, a native of Japan, and first mentioned by Thunberg, in his work, "*Flora Japonica*," published in 1784, is, according to Mr. Fortune, to whom he (Mr. Bateman), was greatly indebted for some valuable memoranda, "a common fruit tree both in China and Japan, and its fruit is highly esteemed by the natives of both countries. There is a single-seeded variety which is most valued. The cultivation of this tree extends from south to north over 7° or 8° of latitude in China—that is, from Canton in the south, to Nanking in the north. The climate between these lines of latitude differs very considerably, particularly in winter, the northern part being much colder than the southern, but in all parts the summers are very warm; indeed, the thermometer in the shade frequently rises above 100° Fahr. in the north at Shanghai, while I never knew it higher than 92° in Macao or Canton." The tree, continued Mr. Bateman, also succeeds in the Botanic Garden of Saharunpore, and has extended along the islands along the coast of the Mediterranean. He had met with it in every garden at Cannes, scenting the air in November and December last, with its agreeable aromatic flower; and there, an exceptional frost notwithstanding, it had set abundance of fruit, which were not ripe before he was obliged to leave. Such is the estimation in which it is held, that quantities are preserved at Grasse (some of which Mr. Bateman exhibited). He could call on the noble President as a witness to its merits, he having partaken of an omelette *à la Néflier du Japon* (Japanese Medlars), and pronounced it excellent.

Mr. Fortune, from the fact of the different climates in which the Loquat flourishes, was of opinion that it might be easily cultivated in an artificial way in countries like our own, where the climate is not suitable to its requirements. "What, then," said Mr. Fortune, "are those requirements? I believe them to be rest in winter, and particularly a hot summer and autumn. This rest in winter may be given by cold, or by dryness, or by both combined. In proof of this I may mention that the tree succeeds admirably in the north-west provinces of India. I met with it in the Government garden at Saharunpore in as fine condition as it is seen in China or Japan. Further, I believe it succeeds perfectly in the south of Europe, in the north of Africa, and in the islands of the Mediterranean. In all those countries it has the two essentials—namely, a cool or dry winter, and a warm summer and autumn.

"In the latitude of London the Loquat is all but perfectly hardy. A tree growing against a south wall, and without any protection whatever, used to be in the garden of the Society at Chiswick twenty or thirty years ago, and may still be there. It rarely produced any blossoms, and never fruited. It wanted something more than our northern climate could supply. What that something is I have already indicated in describing the climate of its native country and of those other countries in which it is found to be at home. Give it the temperature and the rest it receives in any of those countries, and this tree will not only flower freely, but also produce an abundance of fruit in due season."

In a book which had been kindly lent him by the Linnean Society, the "*Jardin de Malmaison*," edited by M. Ventenat, and published at Paris on the 30th Germinal of the year xi. of the French Republic, corresponding to our 30th of April, 1803, there was a figure of the plant in flower; but it had been figured before that by Thunberg, and indeed the plant itself was introduced into England by Sir Joseph Banks in 1787. This work, however, came to us under circumstances of peculiar interest, for there was an interesting letter from M. Ven-

tenat written by desire of Madame Buonaparte, afterwards the Empress Josephine, to Sir James Smith, President of the Linnean Society, begging his acceptance of a copy of the work, and regretting that as almost all the plants at Malmaison had come from England, there was nothing that would be new to him. A hope was, however, expressed, that as orders had been sent out to all countries of the globe to collect plants and seeds, he should be able to do better by-and-by. (This hope was frustrated by the battles of Nile and Trafalgar, which placed the empire of the seas entirely in the power of England.) Allusion was also made to a very choice herbarium formed by Madame Buonaparte, and in which she took a lively interest, and to which it was hinted any addition would be most welcome. Sir James, with true English gallantry, in reply offered to the illustrious lady his sincere acknowledgments, and promised to send anything that could be spared, either dried plants or seeds, that would be likely to interest her.

To proceed with the subject of the Loquat. It did not appear to have fruited at Malmaison. This, however, was reserved for the county with which he (Mr. Bateman), was connected—Staffordshire, for on February 2nd, 1819, a letter from Lord Bagot was read before the Horticultural Society, in which an interesting account was given of the flowering and fruiting of the plant at Blithfield, and high testimony to its merit. Sir William Coke, who was on a visit to Lord Bagot, had been in the habit of eating large quantities of it in Ceylon, but never tasted any so good as Lord Bagot's. The tree which fruited was wintered out of doors and then taken in in October, and plunged in the tan bed of a stove.

Mr. Bateman believed that he was the next to fruit it about the year 1827; but it was turned out at once in a corner of a tan bed bricked off. It flowered freely, but fruit did not set well; only a dozen were produced, but these were delicious, juicy as a Grape, with the colour of the Apricot, and in flavour a combination of both. Afterwards, the larger the tree grew the fewer were the fruit; there were only five in the second year, and none in the next, and becoming tired of this the tree was grubbed up. Perhaps if the flowers had been artificially fertilised more fruit might have set, but there were no bees or insects to do it in our winters as at Cannes. Mr. Loudon also mentioned one or two instances of fruit having been produced, but between that time and this, a period of forty years, Mr. Bateman said he had only heard of it some three or four times. The fruit was occasionally to be seen in Covent Garden Market, but it was very bad. At Malta the sailors touching there made themselves ill by gorging themselves with the fruit, which they call Kill-johas; but these were not fair examples, and we might assume that when properly ripened it is an excellent fruit. The only question is how to obtain it.

The plant, Mr. Bateman added, is nearly hardy. There was a fine plant of it against a wall in the garden at Chiswick, but it was killed by the severe winter of 1837-38, and it never flowered. No doubt at one period the tree requires great heat, and that a rest either by starving or roasting is also required. Mr. Fortune recommends "a cool and dry winter, and a warm summer and autumn;" but here we are met by the difficulty that not only as hitherto artificially cultivated, but as acclimatised in Provence, the tree always flowers in the winter and ripens fruit in the spring. Either, therefore, this constitutional peculiarity must be changed and overcome, or means must be found to make it set its fruit more freely. Its winter flowering, though a difficulty, is also an advantage, as such flowers and fruit are desirable. Mr. Bateman concluded by inviting suggestions on the subject.

Mr. Saunders believed the Loquat to be a very wholesome fruit, indeed, as much so as the Peaches, which would have evil results if partaken of, as the sailors did, in excess. With regard to the Encalyptus, if the leaves were broken they would be found very aromatic, for they contain a powerful essential oil. The trees were fast-growing, and the wood of nearly all the species was very strong, durable, and heavy, sinking in water. Some of them grew upwards of 200 feet in height. Mr. Berkeley had drawn attention to a remarkable specimen of *Seilla campanulata*, and he would just add that all spring flowers had developed themselves this season in an unusual manner.

CULTURE OF ALLOPLECTUS CAPITATUS.

THIS may well be recommended to any one desiring to grow a very beautiful stove plant. Under good treatment it rises from 3 to 4 feet high, attains from 2 to 3 feet in diameter, and is remarkable for the singular beauty of its flowers as well as for its handsome foliage. The flowers are small and tubular, of a pale yellow colour, each inserted in a large brilliant crimson calyx, and the whole borne in large heads. The leaves are of great size, of a fine deep green; the midribs and stalks, like the calyx, are of a bright crimson. It is a native of Colombia, and was introduced by M. Linden, of Brussels.

Its culture is similar to that of the Gesneras. It requires a light but rather rich soil. I have found it flourish well in chopped turfy loam, fibrous peat, decayed vegetable mould, and a little silver sand. Free drainage is essential; and when the plants are potted in early spring they should have a gentle watering, and be placed in a moist heat. They grow rapidly, and may be encouraged with plenty of heat and a free use of the syringe.

Early in June, as soon as the pots are filled with roots, the plants should be shifted again, and the same treatment continued as before for another month. Then they should be removed into a lower temperature with more air, shaded from the sun, and placed near the glass. Here they will speedily show flowers.

When the blooming is over cut down the stems about half way, and give only sufficient moisture to keep the plants from becoming quite dry until after new shoots are made. The following season, after being repotted, they will produce an abundant supply of their attractive heads of bloom.

For increasing stock, cuttings may be made of the leaves at the upper part of the stem. Cut them off with the bud at the base entire, and insert them in pots of light soil with about an inch of silver sand at the top; cover with bell-glasses, and plunge the pots in a brisk bottom heat. The sand should be kept just moist, and no more. As soon as they begin to grow give air, and when they are well rooted pot off in the same compost as recommended for the older plants. They should be shaded for a while until they have become established. Each leaf will strike well enough, but the young shoots make better plants.—CHARLES ROBERTS, *Dorfold Hall*.

HYBRIDISING AT THE CHISWICK GARDEN.

It is certainly very gratifying to know that the Council of the Royal Horticultural Society intends appropriating the whole of the amount realised by the sale of these magnificent varieties of *Coleus* to the further development of experiments in the Chiswick Gardens. I think this is a step in the right direction, and one likely to produce good results.

The Council having wisely decided on this course, the next thing to be considered is how best to encourage and improve that important and most interesting branch of science—hybridisation. I trust I may not be thought presumptuous if I offer a few suggestions which occur to me, and which I think likely to bring about this desirable end.

1st, A suitable house should at once be erected.

2nd, More assistance should be given to Mr. Bause, so as to enable him to devote more time to this most interesting study, which he has so successfully pursued up to the present time under difficulties.

The handsome sum obtained by the sale of the *Coleus* hybrids must impress every one with the idea, that besides enriching our gardens with many valuable plants, the Society will at the same time be diffusing much useful knowledge, and also realising large sums of money, which may be used for the advancement of floriculture and horticulture in general.

For the sum realised by the sale of the *Coleus* a span-roofed house 100 feet by 19, in every way suitable for the purpose of hybridisation on an extensive scale, could be erected. The house should be divided into five 20-feet compartments, one of which should be used for the hybridisation of tropical plants, the next for plants requiring an intermediate temperature, the third for all kinds of softwooded plants, the fourth for greenhouse and New Holland plants, and the fifth for hardy plants.

Each compartment should be heated separately, so that the supply of artificial heat might be regulated to a great nicety. This would be best done by taking a flow and a return pipe outside of the house from one end to the other. The pipes for heating each division should have a stop-valve on the flow, and also on the return, and these valves should be so placed in each compartment that they could be easily reached from the inside.

The internal arrangement of the structure should consist of a walk 3 feet wide through the centre of the house, with a bench 3 feet 6 inches wide on each side, made of strips of deal three-quarters of an inch thick, and 3 inches wide. A space of half an inch should be left between these strips, so that the air, which must be admitted as near the ground level as possible on each side of the house, may circulate freely amongst the plants after their blossoms have been fertilised. The ventilators must, however, be covered with fine perforated zinc, so that all insects may be excluded. The ventilators must also be made to fit closely, so that the air may be excluded at the time the plants are undergoing the process of fertilisation. Provision, too, must be made for the escape of impure air at the apex of the roof. These ventilators must also be covered with finely perforated zinc to exclude insects, and all the laps of the glass should be puttied-up, so as to prevent the wind from blowing through them, and also to prevent the admission of insects.

If the house were placed so that the ends should face the east

and west, the pipes for heating it ought to be arranged on the south side. Over these a small pit from 4 to 7 feet wide might be erected at a small additional cost, and in this large numbers of the seedling plants might be grown. It would also be found invaluable for many other purposes in an establishment like Chiswick, where so many plants are required for presentation to Fellows of the Society, the beautifying of the gardens at South Kensington, &c.

Up to the present time too much money has been spent on the gardens at South Kensington, and too little on Chiswick; but I hope better times are in store for Chiswick, and that more money will in future be granted for the proper keeping of this fine old garden, which is now, under Mr. Barron's skilful management, beginning to assume a position more worthy the Royal Horticultural Society.—J. WILES, F.R.H.S., *Ashburnham Park Nursery, King's Road, Chelsea*.

MY ORCHARD-HOUSE JOURNAL.

April 25th.—Finished the thinning of Apricots. So thickly had they set, that a bushel of the young fruit has been gathered from trees in pots. Plums have set in equal abundance, so that severe thinning will have to be practised.

May 3rd.—Our first hot day, thermometer at 2 P.M. in the open air in the shade, 77°; in the orchard house, also in shade, with ventilators and doors open, 95°.

May 4th.—Thermometer in the open air at 2 P.M., 65°; in the orchard house, 80°. In the Cherry house the earliest kinds of *Gnagnes*, the *Lamaurie* and *Guigne Très Précoce*, are commencing to colour—a sort of pleasant foretaste of summer. The fruit of Peaches and Nectarines are the size of beans, and most abundant. The trees have been infested with the brown aphid (*Aphis persicæ*), which have been easily destroyed by the quassia mixture applied with a small painter's brush.—T. R.

NEGLECTED BORDER FLOWERS.

How refreshing it is to see that there are a few people amongst us still interested in our border flowers, and, no doubt, there are many more who could tell us of their pets. I trust the interest in them manifested of late in the pages of "our Journal," will not be suffered to flag until the delights of our early days are restored to more than their original places.

I have just now under my eye a race of the neglected ones, which I have made up my mind to say a word in favour of, I mean the *Epimediums*. We seldom see them unless we chance to peep into some of our old-established nurseries, where such plants are cared for.

I am quite of opinion that the *Epimediums* are worthy of far more extensive cultivation than at present, for they are in reality spring flowers, and there is no difficulty in cultivating them. Some of them also are not to be despised for in-door decoration early in spring, if grown in pots for that purpose. Especially I would instance that gem of the race called *rubrum*, with its bright red flowers, and for a time without leaves.

Epimediums like a moderately moist, shady situation, but not close confinement, for they delight in a pure atmosphere, being inhabitants of elevated situations; they will grow in many situations, and in different soils, but to have them under control and in good condition, treated as follows I think they will give satisfaction.

A bed or border for their reception may be thus prepared. Take out the soil to the depth of 20 inches, in the bottom place a little rough drainage to carry off any superfluous or stagnant water, cover the drainage with litter or other material to prevent choking up, then fill the remaining space with compost to 4 inches above the ground level to allow for the soil sinking. The compost which I use consists of two barrowloads of friable loam, half a barrowload of good, sound, sandy peat, half a barrowload of leaf mould, and a liberal sprinkling of broken grit, with coarse river sand to keep it porous. Let the soil of the bed settle pretty firmly before planting.

Should it be deemed desirable to grow *Epimediums* in pots for plunging, or otherwise, the compost named will answer for them, care being taken to plunge them in the shade, attending to watering them as they may require. Sprinkling overhead is beneficial to them occasionally.

There are several kinds worthy of cultivation. The following are what I consider the best of the race, but tastes vary:—*Epimedium alpinum*, red and yellow; *E. grandiflorum*, white; *E. macranthum*, white; *E. sulphureum*, yellow; *E. pin-*

natum elegans, yellow; and *E. rubrum*, red, which I think is the gayest of the race. There are others equally deserving of cultivation, but these at present are my choice.

LIST OF PLANTS IN FLOWER.

April 2. <i>Ulmus montana pendula</i>	April 18. <i>Spiraea lavigata</i>
<i>Ribes speciosum</i>	" 20. <i>Iris pumila</i>
<i>Viburnum opulus sterilis</i>	<i>Corydalis nobilis</i>

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

COCHLIOSTEMA JACOBIANUM (General Jacob's *Cochliostema*). *Nat. ord.*, Comelyneae. *Lim.* Monadelphia Triandria.—Native of Ecuador. Flowers pink and blue, slightly fragrant. (*Bot. Mag.*, t. 5705.)

LYCASTE BARRINGTONIÆ, var. *GRANDIFLORA* (Large-flowered Mrs. Barrington's *Lycaste*). *Nat. ord.*, Orchidaceae. *Lim.*, Gynandria Monandria.—Native of West Indies and South America. Flowers white, partially green-tinted. (*Ibid.*, t. 5706.)

BEGONIA FALCIPOLIA (Sickle-leaved *Begonia*). *Nat. ord.*, Begoniaceae. *Lim.*, Monoclea Polyandria.—Native of Peru. Flowers light rose. Leaves red-purple beneath, green spotted with white above whilst young. (*Ibid.*, t. 5707.)

ONCIDIUM CECUTILLUM var. *NUBIGENUM* (Alpine *Oncidium*). *Nat. ord.*, Orchidaceae. *Lim.*, Gynandria Monandria.—Native of Ecuador, at an elevation of 11,000 feet on the western side of the Andes ridge. Flowers white and purple. (*Ibid.*, t. 5708.)

LONICERA STANDISHII (Standish's Honeysuckle). *Nat. ord.*, Caprifoliaceae. *Lim.*, Pentandria Monogynia.—Native of China. Flowers white. "A charming, fragrant, early-flowering Honeysuckle." It is a deciduous shrub. (*Ibid.*, t. 5709.)

TROPEOLUM—Mrs. Treadwell. Flowers deep scarlet. First-class certificate from the Royal Horticultural Society's Floral Committee. (*Floral Mag.*, pl. 385.)

ONCIDIUM MACRANTHUM HASTIFERUM.—Flowers golden yellow. Believed to be a native of Peru, and requiring cool treatment. (*Ibid.*, pl. 386.)

PERSIAN CYCLAMEN.—Purity, white. Delicate, white with pink base. *Mauve Queen*, mauve with crimson base. *Excellent*, white with crimson base. *Norolty*, white tinged with pink, base purple. *Firefly*, crimson. (*Ibid.*, pl. 387.)

ATACIA CRISTATA.—Native of the Delta of the Ganges. Novel and curious. (*Ibid.*, pl. 388.)

AURICULA Colonel Champneys.—"This remarkably fine Auricula was raised from the variety called Chapman's Sophia, fertilised by the pollen of Lightbody's Richard Headly. It belongs to the grey-edged class, and is remarkable for its large showy pipe, the ground colour of which is a bright violet, partaking of the shade of colour met with in Sophia, while the eye and paste are very round. The truss of flowers is large, bold, and attractive, indicating a free habit of growth and a robust constitution. We learn, moreover, that it is a variety which increases freely. There can be no doubt that

this will become a standard variety, for it is not only very distinct, but it is also one of the most attractive flowers in the Slough collection.

"A first-class certificate was made to it at one of the spring shows of the Royal Botanic Society. It has been shown again this season, on two occasions in great beauty, on one of which a further award was made to it."—(*Florist and Pomologist*, 3 s. i. 97.)

WARNING TO INTENDING EMIGRANTS.

UNDER the above heading in page 201 of the Journal I noticed a communication from "W. T. G.," which is calculated to mislead intending emigrants.

I am somewhat of a traveller, and have more than once traversed that portion of the United States between the head of Lake Superior and the Gulf of Mexico, and from the Mississippi river to the Atlantic Ocean, and, to complete my education, visited "W. T. G.'s" "happiest land upon earth," as well as some of his "most distant colonies." He claims to be a "horticulturist," and as I possess a smattering of art horticultural, like him I propose addressing horticulturists. Having travelled, and with eyes open, I contend that my conclusions are as valuable as those of "W. T. G."

With regard to the Pear on the Quince in the "western part of the State of New York," I can assure your readers that in the very locality mentioned are numerous nurseries, varying from 50 to 900 acres each, and each proprietor cultivates immense numbers of the Pear on the Quince. If the climate were not adapted to its growth they would abandon the culture. I unhesitatingly assert that when the Pear on the Quince is planted in proper soil, and receives proper culture, success is certain in any portion of the United States north of the 35th deg. of north latitude. If planted in a heavy undrained soil loss may be expected. I reside near the city of New York, and have under cultivation an orchard of upwards of eight hundred trees on the Quince, some of them planted more than eight years, and not one has been injured by frost, and I never heard or read of a Quince stock being injured by frost unless planted in an unsuitable soil. If space permitted I could give you positive facts regarding Pears on the Quince in many portions of the States—their size, age, and productiveness. If one person by injudicious selection of situation and soil happens to be unsuccessful, that is no reason why "W. T. G." should resort to an unqualified condemnation of a vast country with a diversity of climate, and in its adaptability to fruit culture unequalled. The "western part of the State of New York" is but a small portion of the United States, and ere "W. T. G." had given publicity to his opinions he should have traversed a larger portion of this vast country.

With regard to the Vine, I have a vineyard upwards of three acres in extent, and have visited numerous others in various localities. I endeavour to keep myself posted up on Vine culture, but never saw or heard of a case similar to that referred to by "W. T. G." If the soil were heavy, with deficient drainage, an accident might occur; but no sensible man would think of planting Vines in such a situation. If such accidents frequently occurred you would not find thousands of flourishing vineyards in the United States, and numerous nurserymen sending out their tens of thousands of Vines annually. Admitting that such a thing occurred annually in the colder portion of the United States, that is no reason why the intending emigrant should settle there, but, on the contrary, if he wished to engage in Vine culture, let him settle in a warmer portion of the country, where "W. T. G.'s" imaginary winter mean of 10° Fahr. could not be found.

For the information of intending emigrants I will give a few figures. The annual winter meeting of the Lake (Erie) Shire Grape-growers' Society was held at Cleveland, Ohio, from the 19th to the 21st of last February. Mr. Lewis, of Sandusky, read some statistics regarding the yield in 1867 in the vicinity of Sandusky, as follows—

Lbs. table Grapes shipped from Sandusky in 1867	1,822,000
Lbs. wine	250,000
Gallons wine pressed at Sandusky, Peninsula, Catawba	
Island, Kelly's Island, Bass Islands	470,000
Lbs. of Grapes from which the above was pressed	4,600,000
Total Grape crop of 1867, lbs.	6,622,000
Average yield per acre, lbs.	4,480

Strange as it may seem, the above yield was from Vines grown upon the eastern shore of Lake Erie, a portion of that lake forming the western boundary of the "western part of the State of New York;" and what is most remarkable, the inhos-

pitable region described by "W. T. G." Here we have statistics carefully collected from positive cultural results, and not a dark picture and wholesale condemnation based upon the misfortunes of a particular individual, who, probably, selected an unfavorable situation for his vineyard.

With regard to ground mice I plead guilty, and admit that like English hares and rabbits they occasionally prove troublesome; and careless culture and neglect furnish field mice shelter. If the owner of the orchard referred to by "W. T. G." had been posted up, he would have avoided his misfortune if he had been aware of the existence of field mice in such unprecedented numbers. A few spades of earth thrown against the trunk of each tree in the autumn would have prevented his misfortune.

"W. T. G.'s" remarks, based upon a solitary case, are calculated to lead intending emigrants to believe that Apples cannot be grown in the United States. My Apples, standard and dwarf, number 385, and in no instance has one of them been injured by mice. I have no hesitation in stating that in no other portion of the world, in accordance with the number of population, are so many large and thrifty Apple orchards to be found; every farmer, large or small, has his orchard. If these are facts, field mice cannot be very destructive. A solitary instance of unsuccessful culture is no evidence that field mice are so very troublesome. As an evidence of the results of Apple culture in the United States, I would advise "W. T. G." to visit Covent Garden Market, and inquire of vendors where they obtain their Newtown Pippins, Greenings, Northern Spys, and Baldwins. If still unsatisfied, let him visit Liverpool when they are unloading the New York steamers, and the delicious aroma proceeding from innumerable barrels of Apples will convince him.

"W. T. G." enters the field of climatology, and asserts that the "average mean during the winter months is about 10° Fahr." To clothe this statement with the mildest term, it is an error. The lowest mean during the winter months in the settled portions of the United States is 20° Fahr. This statement about the lowest mean would lead "intending emigrants" to believe that the United States is a hyperborean region, only adapted to the production of white bears and walrus. On the contrary, diversity of climate is the rule, and the intending emigrant can suit himself as regards climate, with a winter mean of temperature varying from 20° to 70° Fahr., and in the warmest portion with a minimum of 65° Fahr. The intending emigrant can settle in the north, where the Apple and dwarf Pear are a success, or in balmy and unequalled Florida, where he can shelter his new home with the Banana, Orange, Olive, and Pal'm.

The hedge business is the most amusing, for if the "enterprising English farmer" alluded to had inquired of the merest tyro, he would have been informed that the Hawthorn is not adapted to this climate. I have carefully examined hedges in various portions of England, but never saw anything to equal the hedges of Osage Orange, Arbor Vita, Norway Spruce, and Gardenia florida, which I have seen in this country. But the other day a friend was describing to me a hedge of Camellia japonica, 200 yards in length, compact as a wall, and stated that during the spring months it was gorgeous. If "W. T. G." had seen, as I have, hedges 6 and 8 feet high of the fragrant Gardenia, his ideas would not have been so cabined, cribbed, and confined.

"W. T. G." asserts that "for at least four months in the year not a spit can be turned, and it often happens that for the best part of six months stern winter holds everything with an iron grasp." It is self-evident that the opportunity for observation on the part of your correspondent has been very limited—confined to the coldest portion of the United States, and surely the intending emigrant is not compelled to follow in the footsteps of "W. T. G." I can assure intending emigrants that in other portions of the United States they may gather Oranges, Lemons, and Green Peas from November to March; early Potatoes by the 10th of March, and Melons and Tomatoes by the 10th of May, all from the open ground, and without the "boiler-power and piping" referred to by "W. T. G." If the intending emigrant dislikes the extreme north, and objects to have his cot surrounded by tropical fruit, he can select any climate to suit him between the winter means previously referred to.

For the information of "W. T. G." and intending emigrants I may remark that the winter mean of 10° Fahr. is found to cross the centre of Newfoundland, then about 60 miles north of Quebec, thence to the head of the Ottawa river, northern

margin of Lake Superior, and then in a north-westerly course until it crosses the 50° of north latitude.

Last, though not least, is a lengthy reference to insect enemies. Again I plead guilty, and would ask "W. T. G." What country is without them? Even the "happiest land upon earth" is troubled with these unwelcome visitors, and I fancy as much as the country with a winter mean of 10° Fahr. To prove that insect enemies do not destroy all trees and fruits, I need but cite the fact, that all railroads leading to our large cities run during the fruit season special daily trains for the conveyance of fruit alone. With regard to vegetables, I can assure intending emigrants that American markets are well supplied with vegetables of good quality and at a reasonable price, in despite of the numerous insect enemies.

"W. T. G." enlarges upon the enemies of the agriculturist, as though the English farmer had nothing to contend with. To prove that insect pests do not destroy all the grain, I can assure them that we raise enough for home consumption and annually export immense quantities to England and other countries.

If the picture painted by "W. T. G." is an unvarnished one, why is it that over 300,000 emigrants annually land in the United States, and but few return to fatherland? The majority are agriculturists, and settle on the broad and fertile plains of the west—the granary of the world. A few, through mismanagement or other causes, are unfortunate, return to their former homes, and misrepresent the United States. If positive and reliable data regarding the productions and climate of the various portions of the United States would interest your readers, it would afford me pleasure to furnish them. What intending emigrants require is reliable information based upon observations extending over a large portion of this vast country, and not confined to a limited area, with a winter mean of 10° Fahr.—AL FRESCO, *Passan, N.J., U.S.A.*

PROGRESS OF GARDENING IN NEW ZEALAND.

The following is a lecture delivered before the Horticultural Society at Canterbury, New Zealand, by Mr. Wilson, President of the Society. He is a nurseryman, and after a few preliminary observations, he observed that

On the present occasion he should confine himself to a rapid survey of the introduction of the principal trees and flowers which had been brought into Canterbury. The first tree he introduced was the *Salix babylonica*, or Weeping Willow. This was sometimes confounded with the *Salix Napoleon*, so called from its growing around the tomb of Napoleon at St. Helena. The Canterbury Willow derived its botanical appellation from that affecting passage in the 137th Psalm—in which the captive Israelites are represented as hanging their harps upon the Willows that grew by the banks of the Euphrates, when they refused to sing the Lord's song in a strange land. Lady Mary W. Montague, the wife of the then English Ambassador at Constantinople, sent some sprays of these trees to Pope the poet, who planted one of them in his garden at Twickenham, and from this tree have sprung all those now in England. The Willows introduced into Akaroa were some cuttings from those planted by Madame Bertrand around the grave of Napoleon, brought into that place by some of the early French settlers; but the Weeping Willow properly so called was of eastern origin. He had brought the first Willows from Wellington, and had given some to the late Archdeacon Mathias, who planted them in his garden at Riccarton.

The introduction of Walnut trees into Canterbury first took place in Akaroa, where they have thriven perfectly. They had first been brought into German Bay by the early French settlers. Upwards of 7000 plants had been cultivated there, and were at first sold at the rate of £12 10s. per hundred. He did not doubt that Walnuts would even form an article of export, so rapidly did the crops increase.

The French settlers, thinking that they were coming to a warm climate, had brought with them some plants of the Vine. Two of the varieties were the White Muscadine and the Black Hamburgh. These had flourished well, but the fruit was small.

The French had also imported some Olive plants, but although the trees had thriven and had attained a considerable size, they had not as yet borne any fruit.

The first Apples introduced were brought by Mr. Deans, and were the variety known as the Leathercot or common Russet; these he brought from Nelson in the year 1815. Only three trees arrived from that province.

The same gentleman had also brought the first Pear trees into Canterbury; and although some difficulty had at first been experienced with regard to them, his perseverance was rewarded by a good crop of large-sized Pears.

Mr. Deans was also entitled to the credit of being the first to bring Plums into the province, and now the finest and best sorts were to be found in it.

The Bishop-designate Jackson first imported timber and forest trees into Canterbury; but as he did not remain here he gave the plants of the Elm, Ash, Beech, and Oak to Mr. Deans, who planted them in his grounds, where they were doing well, and where he (Mr. Wilson) hoped that in process of time a forest rivaling those of the old country would arise.

Another important importation had been Keens' Seedling Strawberry; the honour of bringing this delicious fruit here was due to Mr. Guise Brittan. He (Mr. Wilson), had himself brought some from Auckland—in fact he had procured 3000 plants, and they were now distributed throughout the length and breadth of the province. Mr. Cotton, an English clergyman, had first brought them to Auckland; and it might be added that the same reverend gentleman was the first to introduce bees into that province. As the Strawberry plants were being brought here, a number perished, and only fifteen survived the voyage. From this sprung, as he had remarked, all those now in Canterbury.

Another importation which had greatly added to the beauty of our gardens was the Scarlet Hawthorn. It was a peculiarity of this tree, that although it produced abundance of haws they were generally barren, and it was necessary to propagate the plant by budding it on a common Thorn. They originally came from Auckland, and the large trees now in Dr. Stedman's garden were some of the original stock.

The useful timber tree, the *Pinus pinaster*, was introduced by the Rev. G. Cotterill, who gave some seeds brought by him from England to Mr. Davie, who planted them where Cookham House now stands. Some still survive in a garden near that spot, and are the largest in the province.

Dr. Earle, of the Grange, had been the first to cultivate the Blue Gum; this had sprung up accidentally from some seeds from Hobart Town, sown in his garden. He had carefully tended it, thinking it was a plant of the old English Honey-suckle, until an Australian settler saw it, and he recognised it as a Blue Gum, and this was the parent of all the Blue Gums in Christchurch.

The Norway Poplar and the Black Italian Poplar were brought here by Mr. Phillips, of Rockwood, in the year 1851. These were most useful woods for building purposes, as the wood can scarcely be destroyed by fire; it may smoulder, but it scarcely ever blazes.

The *Ribes sanguineum*, or common Red-flowered Currant, was introduced about the same time; as was the Passiflora, or Passion-flower. He had brought this plant from Auckland, where it grows to a large size; the berries are esculent. At the same time he had introduced the Akiaki from Akaroa.

The Portugal Laurel and the Common Laurel were acclimatised by Mr. Guise Brittan, who had planted them round his house, now the Lyttelton Hotel; and although the original plants had long since perished, some offshoots from them were still flourishing luxuriantly at Englefield. The same gentleman had also first planted the Arbutus—a fine ornamental tree, now growing in beauty also at Englefield.

The *Chianthus*, or Parrot's-bill, had originally come from Auckland; the original tree was now growing around Mr. Slater's house in Lichfield Street.

The first Rhododendrons were brought by Mr. Phillips, of Rockwood, who planted them in Mr. Jacobs's garden.

Holly was introduced by Mr. Richards. Mr. Webbe had planted the first Cypress—a most valuable tree, whilst Mr. Vigors had sown the first lawn with English Grass.

The Huntington Willow had been introduced by himself, as had also the common Double Daisy, Cowslip, and Primrose. The first Daisy in the province had been found growing in the street, where Mr. J. D. Macpherson's store now stands; whilst the first Lily of the Valley had been brought by the Rev. W. Aylmer.

The lecturer concluded by alluding to some plants which New Zealand had in turn supplied to England, whence had been derived so many fruits and flowers, mentioning amongst others some of the native Ferns and a species of *Ranunculus*—the *Ranunculus Traversii* (so called in honour of Mr. Travers), which he said now commanded a high price at home. To the late Archdeacon Mathias was due the credit of first forming those Gorse hedges which had proved both useful and ornamental—useful in sheltering the plants in the gardens, and ornamental from their luxuriant blossoms and growth. He must claim for himself the honour of having brought the ordinary and the Cape Broom into use for the purpose of fencing.

FLOWER-GARDEN PLAN.

IN reply to "MAXWELL," we approve of the north and south groups—namely, those to the right and left of the three beds 7, 8, 8; but as you have a uniform edging of blue Lobelia for the six outside clumps, it would much improve them if there

were a narrow string of *Cerastium* next the grass. Then of the three clumps, 7, 8, 8, the central one, 7, planted with yellow Calceolarias, would come in line with Mrs. Pollock Pelargonium on each side. To make the whole very effective, if

- 1, Pelargonium Countess of Warwick, edged with Amaranthus.
2, Pelargonium Bijou, edged on the outside with blue Lobelia.
3, 3, Pelargonium Flower of the Day " "
4, 4, Pelargonium Mrs. Pollock " "

- 5, Pelargonium Cloth of Gold, edged on the outside with blue Lobelia.
6, Pelargonium Golden Fleece " "
7, Calceolaria, yellow.
8, 8, Calceolaria Prince of Orange.

the climate is good enough fill that clump with *Colens Verschaffeltii*, and ring it with *Cineraria maritima* or *Centaurea candidissima*. If this cannot be done, Purple King Verbena

and variegated Alyssum will do very well. Then of the other two beds, one on each side, Prince of Orange Calceolaria might be outside, and a blue-coloured Verbena or dwarf Ageratum in

the centre. We know the change will be liked. The Coleus, if it thrive, will make the whole grand. As proposed, there will be too much yellow in line. We consider the foregoing a very excellent and simple arrangement.

NEW BOOK.

Synopsis Filicum : or a Synopsis of all known Ferns, including the Osmundaceæ, Schizæaceæ, Marattiaceæ, and Ophioglossaceæ (chiefly derived from the Kew Herbarium), accompanied by figures representing the essential characters of each genus. By the late Sir W. J. HOOKER, &c., and J. G. BAKER, F.L.S., Assistant Curator of the Kew Herbarium. London : R. Hardwicke.

WITHOUT any reservation, this is the most useful botanical work upon Ferns that has yet been published. It includes all the known Ferns of our globe, about 2400 in number, and groups them in seventy-five genera, the distinguishing characters of each of which are rendered readily recognisable by coloured plates. Of each species there is a description and brief history; and all being contained in about five hundred pages, it may be well included among the "handy volumes" of science.

Only forty-eight pages had been printed when Sir W. Hooker died; the remainder of the work was confided by his son, Dr. Hooker, for supervision and completion to Mr. Baker, and every page bears testimony to the care and ability with which he has executed the work he undertook.

WORK FOR THE WEEK.

KITCHEN GARDEN.

MAY is always a busy month in the kitchen garden, for young crops have to be thinned out, others have to be earthed up, and some have to be transplanted, watered, and shaded; while successional crops require to be sown more frequently. *Asparagus*, when the plants that were planted in March have pushed two or more heads each, the weakest must be regularly cut away as the strong heads appear, so that at the end of the first season not more than two, or at most three, shoots are allowed to come to maturity on each plant. When the ground has been properly prepared stretch a line, and take out a trench sufficiently wide and deep to allow of spreading out the roots, and cover the crowns about 2 inches. The roots should be carefully taken up, avoiding all cutting or injury, and any that are decaying should be rejected. During the growing season keep the ground free from weeds, and the surface free and open by frequent hoeings. A soaking of manure water may be given with advantage when the weather is dry. *Beet*, sow the main crop in drills 1 inch deep, and from 15 to 18 inches apart, covering with friable soil. If possible, select a dry day, when the ground is in good working order, for putting in the seed. Nutting's Selected and Henderson's Pine Apple are good sorts. *Celery*.—For transplanting, prepare a bed of rotten manure 3 inches deep, covering it to the depth of another inch with light sandy soil. Prick the plants out on this about 3 inches apart, water freely, and until they take hold of the soil shade them from bright sunshine. In the beginning of the month the Celery sown in February and transplanted in March will be fit to plant out in trenches 4 feet apart; the trenches to be filled to within 6 inches of the top with good moist rotten dung dug in, and the space between the trenches to be filled with Lettuce, Spinach, or Cauliflowers, planted 12 inches apart. A liberal supply of liquid manure should be given during their growing season. Some soot added to the water is an excellent stimulant occasionally, and all suckers must be removed. *Onions*, sow a patch very thickly on very poor gravelly soil, in order to obtain very large bulbs; these during the first year will make very little progress, and by the time they are ripe and fit for taking up they will not be larger than a hazel nut. Spread them very thinly on a dry shelf during the winter, plant them in March in rows 6 inches apart every way, covering as slightly as possible; and as regards gathering, housing, &c., treat them in the same manner as the spring-sown. Thin out young crops as soon as they are fit to handle. The thinning should be gradual, and always performed as soon as the young plants touch each other; for if they start weakly and are drawn they never become so robust and vigorous as when the light and air are allowed to play freely around them. Seeds of *Sage*, *Thyme*, and *Rosemary* should be sown

on a warm border, also *Sweet Basil* and *Marjoram* two or three times during the season, for use in a green state as well as for drying.

FRUIT GARDEN.

Proceed with the disbudding and removing young shoots from Peach and Apricot trees. Where the fruit of the former is too thick a number may now be cut off; those of the latter will be useful for tarts. In disbudding use a small sharp knife, as pinching the shoots off is apt to cause the wound to gum and canker. Where wood is wanted pinch off the tops of strong shoots, as several good bearing shoots may be thus obtained. Where a shoot will be too strong and only one is wanted, cut it back so as to secure one good lateral. When strong shoots appear where they are not wanted, or the tree is over-luxuriant, allow a number of them to run their full length, taking off the leaves from the under parts of the shoots as they advance. They will thus form channels for the extra sap, and will not shade unnecessarily the wood intended for bearing. In removing shoots at this season thin them gradually, so as ultimately to leave no more than can be exposed to the sun and air.

FLOWER GARDEN.

Rustic baskets and vases may now be filled with soil, which should be of a rather retentive nature, and the plants should be turned out when all danger from frost is over. Flowers of a drooping habit are the best suited for baskets. *Fuchsias* and the like, and *Caleceolaria floribunda*, with *Anagallis cerulea grandiflora* or *Lobelia* hanging down the sides of the basket, will answer well. Auriculas are fading fast, the majority of collections being out of flower. Where seed is not required the heads may be cut off not too low; put the plants in a shady situation, giving them the requisite attention as to water and cleanliness. They are too often neglected after blooming time. Tie up *Carnations* as fast as they require it; and if green fly make its appearance dust Scotch snuff slightly over them, or brush the insects off with a large camel-hair brush. Keep the pots free from weeds, which now spring up fast. Tie *Pinks* to sticks.

GREENHOUSE AND CONSERVATORY.

Keep down the temperature in the conservatory by all possible means, in order to prolong the flowering of the plants, and as the syringe would soon injure the appearance of plants in flower, the rose watering pot must take its place. Flood all spare parts in this house morning and evening. Continue to encourage the greenhouse plants to make rapid growth during this month, and keep the atmosphere always moist at night during this period. As few plants are allowed to flower in this house if there is a conservatory, the syringe may be used freely in the afternoons of fine days. Training and regulating the growth of all pot plants, as well as watering and killing insects, must be attended to while the plants are growing.

STOVE.

The usual routine of watering and keeping the plants clean and properly trained is all that is necessary here for some time. Some few plants may want shifting now and then, and all the young stock must be shifted by degrees as the plants advance, but no precise time can be pointed out for this work; the whole depends on the state of the plants and the means of the cultivator.

FORCING PITS.

This is just the critical time when a little oversight may cause much murmuring next winter. Look over your forcing plants the very first opportunity you have, and consider how many you may want of those most esteemed by the family, always making an allowance of 20 per cent. for failures among those forced in December.

PITS AND FRAMES.

These structures will almost be done with for this spring's planting, but they must not be idle, as it is time to commence propagating for next year. Cuttings of dwarf *Phloxes*, *Alyssum saxatile*, *Arabia*, &c., must now be put in. If there is a full supply of autumn-flowering plants to succeed the annuals, one of these pits may be used for something else. If the old *Cabbage Rose* is wanted on Christmas-day, take up half a dozen pot plants from the reserve ground, plunge them in old tan, sand, or anything else in one of the cold pits, and treat them like *Heaths* till next August, when you may turn them out under the shelter of a north wall, prune in September, and introduce them into a forcing pit on the 1st of October. Continue to increase the stock of *Verbenas*, *Heliotropes*, *Salvias*, *Fuchsias*, and all other plants that may be required for filling

boxes, vases, and blanks in the beds and borders in June.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

THE rain and hail of April 27th, followed as it was eventually by milder weather, has given all vegetation an impetus. The fields are putting on their summer livery, and the grass of lawns and meadows is growing as if by magic. With plenty of grass mowings we need never be at a loss for a little bottom heat, provided we keep that heat low enough down, or far enough from the roots of the plant we thus wish to assist. The fierce sun, and the drying winds of the three last days of the week, necessitated additional watering, or some shelter for all plants a little tender, or that had been newly turned out. A little shelter often does more good than the watering pail, when the ground about the roots is moist enough. A few evergreen twigs to shade and shelter newly-turned-out Cauliflower plants, &c., enable them to hold their own in such weather with little watering. We should never forget that the more we water the ground at this early period, the more we cool it, unless we manage to water with heated liquid, and that is no easy matter, where much watering has to be done.

Took the opportunity of hoeing well between the rows of Onions and Parsnips, the Carrots not having come up sufficiently as yet to enable us, as respects them, to go through that operation. Besides cutting up all the little weeds, the breaking up of the caked surface does good, more especially after the ground has become warm enough, as the loose surface keeps the ground cool beneath it, and the temperature of the soil more equal, as it absorbs less heat during the day, and radiates less heat into the free atmosphere at night.

Sowed a border with Kidney Beans, not of the kinds that we like best, but those we could obtain, as some of the best sorts were not to be had this season. These, Scarlet Runners, and Peas, slightly covered with red lead before sowing, have not been touched by birds, slugs, or snails. The black-backed yellow-bellied kind of the latter mollusk is very difficult to extirpate, as hardly anything will injure it, except what would likewise injure the plants. Planted out a nice piece of Dwarf Kidney Beans from 5-inch pots, four beans in a pot, without disturbing the ball, and will give these protection for a few weeks. A box or two with seedlings will be turned out separately in a few days, and these, too, will receive protection for a time at least, with a few evergreen branches. As already intimated, a fierce sun is as injurious to such crops when fresh turned out as a cold night. Contrary to our wish, we have had to find space for a row in 12-inch pots on a shelf in the late vinery—at least, for a time, for these plants seldom show insects until they reach the bearing period; but we had an accident with two previous crops, which in a night deprived us of good gatherings for a month or five weeks. Some rats had found their way into the pit by making a hole in the wall plate, and cut one sort as completely down as if a number of sheep had trampled them. The sort so treated was the White Canterbury, hardly a single leaf was left uncut and uncut. We were congratulating ourselves that the rats had shown some merciful consideration, as at first sight a fine lot of a cream-coloured bean just setting its pods, and with a dense mass of flower-buds open and opening, seemed untouched, but on opening the lights we found that though not a leaf or stem had been touched, not a single flower bud or young pod had been left. The intruders had mounted the stems, and the little sticks, and cleared off every flower bud as neatly as if it had been removed by small scissors, and all seemed as if they had been eaten, for scarcely a bud was left on the ground. By cutting the plants back we may obtain a second crop, but far from equal to the first. The difference made in the treatment of the two sorts is worth recording. But for the removal of the flowers and young pods there was nothing in leaves or stem to denote that this second lot of Beans had been visited by such intruders. After much trouble we only succeeded in trapping a young rat, for the Beans being grown over an open bed of manure and leaves, even a good ferret could help us but little. A rat will be hard driven, however, if he will consent to remain in a place where a ferret has been.

Much other work was of a routine character, sowing succession crops, pricking-out Celery and Cauliflowers, and watering the same when needful. The first-pricked-out Celery is now strong and good, and had the help of glass at first, but for three weeks or a month has merely some laurel boughs over it

to break the force of the sun's rays in imitation of what it would have had in its natural habitat, and its appearance would indicate that this is the treatment it most prefers. At an early period Celery will stand still in bright sun. It much likes a flickering shade.

Potted-off Cucumbers for frames, Gherkins and Vegetable Marrow for ridges, and attended to those bearing in pits and frames as previously detailed, much watering being wanted in such weather. The wind being keen and dry at times, we preferred that the atmosphere over the beds should rise 5° or 10° higher in temperature instead of giving much air, but that little was given early, so that the temperature rose gradually. In the bright days of Friday and Saturday the glass was dulled with the slightest sprinkling of water, just coloured with whitening. Some men can do this so nicely with the jet nozzle of a syringe, regulated merely by the finger, that the glass will be equally spattered, and not a single dot will be larger, and most much smaller, than the head of a common pin. Many lights can thus be gone over in a few minutes, and when the squares of glass are large some such slight shading is often of importance when such bright days succeed all at once a period of dull sunless weather. In this dry, bright weather we gave no front air to frames over hotbeds where a high temperature was needed, except a little to Melons in bloom and setting, as a little air right over them, however small the amount, assists the setting process.

FRUIT GARDEN.

Melons.—Rather a singular thing has happened here in a five-light pit heated by hot water, and that for a number of seasons consecutively. The plants in the three lights at the west end generally do very fairly, but those in the two lights at the east end, just as the secondary shoots come away freely almost as uniformly lose their first larger leaves, whilst those near the point will retain their natural healthy green colour. Sometimes the leaves will have brown spots, sometimes the brownness affects the edges of the leaves first, and gradually covers and kills the leaf. Sometimes we cut off these browned leaves along the stem for a length of a foot or 18 inches, bring the stem round again to the centre, and allow the point to grow outwards as a young plant. Sometimes we pull up the plants thus affected, and plant fresh ones, and we may even have to do this for a second time before we secure in these two lights fresh and vigorous growth. The cause has been a mystery to us, and remains so still. The pit is part of a range heated by two 3-inch pipes in front for top heat, and two 3-inch pipes in rubble below the bed for bottom heat. For this period the heat is sufficient, and we may conclude there is nothing in the heating, or why should the three western lights be little or not at all affected? Then we supposed that there might be some condensed deleterious vapour, but we used no dung, and even in general left the thickness of a common tally between the sash and wall-plate at night. Then, again, we surmised that the sun struck on the foliage when it was damp, and that the leaves were thus scalded, and that at least made us anxious to have the foliage dry before the sun reached it in force; but between the east end of the pit and a garden wall there is only the width of a walk, and therefore the sun strikes the western lights of the pit a considerable time before it gets over the wall to shine at all strongly on these two eastern ones. We have also examined the two sashes carefully, and though the glass is very common fourths, still we can perceive no difference between its quality and that of the other lights where no such phenomenon occurs. Over dung beds, and with sashes of the old-fashioned kind, and glass so bad that the like could scarcely be had now as a curiosity, we have witnessed no such appearance. We can decide on neither cause nor cure; for when we succeed at length in obtaining healthy growth it is entirely owing to perseverance, and we are as ignorant as ever of what enables us to cause the healthy growth at last. For three or four seasons the first plants in these two lights have suffered in a similar manner. In the case of all other kinds of plants we have observed no difference as to results beneath these two lights and the other lights of the pit. It is only in Melons that we have noted the difference. We may add that the soil in the five-lights is the same, and when the roots were examined there seemed nothing wrong with them. At present the matter is as much a mystery to us as how to keep away the Cucumber disease, or get rid of it when it comes. When we were visited with it we neither knew how it came or what took it away, or nearly so; and the only

palliatives we could find were poor fresh soil and very frequent planting.

Strawberries.—We have given a lot of Melon plants larger pots to stand in for a few weeks, as we have been forced to devote to Strawberries a five-light pit, that we meant to bring in for Melons, but which must wait a little. These Strawberry plants, showing bloom strongly, had stood in rather a shady place in the orchard house, and did well enough there as regards the production of flower trusses and until they began to open, when they needed more full light and to be nearer the glass. That we may be able to move the plants afterwards without injury we have set each pot on a saucer, the saucer filled with moss covered with rich compost. When pots are set on turf—an excellent plan—they should not be moved until done with. In clearing out to-day some plants which had finished fruiting, we were quite surprised at the strong pull that was necessary to tear the roots out of the turf into which they had run through the hole at the bottom. This fine lot will succeed those standing on turf and soil in the front of the first orchard house, which are setting beautifully; these again will be succeeded by two rows in the front of the late orchard house just opening their flower buds; and a lot more still later, we will place on the north side of a wall, to be forwarded if we think necessary afterwards, to prevent any interval between those in pots and those in the open air. Some blooms of the earliest, as Black Prince, are just opening. This may tend to show beginners that some thought is required to keep up a regular supply—a matter of more importance than gathering great quantities at a time. These Strawberries in pots have been assisted chiefly with soot. Sometimes as much as could be taken between the thumb and finger was strewn on the surface of a pot, and sometimes clear soot water was given alternately with clean water and drainings from the farmyard not over-strong. We have hoed thinly the surface of the ground and mulching between the Strawberry plantations; and had we time and plenty of materials we would rake off the roughest of the mulching, and strew lime thinly along the ground to drive away slugs and snails, and then when the lime was turned into mild chalk we would scatter some soot over the ground, not minding if a little fell on the plants, as the first rains would wash that off before the flowers opened much. Taking all in all, soot is excellent for Strawberries. The syringing with clear soot water has as yet kept the Strawberry plants in the orchard houses free of green fly, as that could be done more freely there than in other places where the green fly made its appearance, as alluded to.

We never saw Apple and other blossom more beautiful than it is this season. Gooseberries seem loaded, as, thanks to a little gunpowder, and other means, we held our own with the birds this season, except in a little orchard, where they had all their own way.

In the hot weather, floors, stages, walls, &c., in Peach houses, vineries, &c., were kept more than usually damp during the day, to prevent the temperature rising too high without giving too much parching air.

ORNAMENTAL DEPARTMENT.

Auriculas should be watered with great care, so as not to spill a drop on the flowers, and when manure water, especially, is used, not a drop should light on the foliage. This is a safe rule to apply in all cases of watering plants with manure water. Regulated corridors and conservatories afresh. It is a bad plan to wait for a great job of this kind being done; it should be attended to daily, so that all plants past their best may be removed, and be followed by plants coming to their best. Nevertheless, the most of us, with this daily attention, find that there are times when we must have a more general clearing-out. For instance, Cinerarias are still showy and useful, but many are past their best, and these were set against a wall and protected by a hurdle with a few twigs drawn through it, and these plants will furnish plenty of cut flowers. Camellias over were moved to the vineries to accelerate growth, and their places supplied with Fuchsias, Scarlet and other Pelargoniums. The faded Azaleas were put by themselves, and those in full bloom were set in the best positions. Ferns were fresh potted and regulated, and much time taken up in giving room to, and getting bedding plants hardened off, for which every turf pit was more than called upon. In all plant places during the week, the drying wind and the scorching sun were prevented from acting injuriously, by a little shading, damping the floors and stages, and giving less air than in quieter weather. The Fern house was shaded by giving the glass a fair coating of whitening and milk, which will remain for the season. Scars

in the glass in orchard houses were sought for and daubed with a little paint.—R. F.

CRYSTAL PALACE.—The programme for the new season of the Crystal Palace had just been published. As the Palace was opened in June, 1854, the present will be the fifteenth season, and no greater sign of its vitality can be given than the liberality of the arrangements which the directors are enabled to offer to the season ticket holders. The policy which has been pursued for the last three years of admitting season ticket holders on all occasions, receives further exemplification this year by the season ticket being made available during the four days of the Handel Festival. As heretofore, the Great Flower Show on the 23rd May, and the Rose Show on the 20th June, will be the chief horticultural attractions of the metropolitan season.

COVENT GARDEN MARKET.—MAY 6.

A few brilliant days have had a marked effect upon our market in a threefold sense—viz., improvement in quality, quantity, and demand. A few early Peaches of excellent quality are offered, and command fair prices. All other articles remain much the same. Among foreign imports we may include Apricots, and Cherries. Heavy consignments of new Potatoes from Lisbon and Cornwall have come to hand this week in good condition.

TRADE CATALOGUES RECEIVED.

J. Carter & Co., 237, and 238, High Holborn, London, W.C.
—Carter's List of Bedding and other Plants for 1868.

Eleombe & Son, Church Street, Romsey.—List of Select Flowering Plants.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix upon the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

BOOKS (A Subscriber).—We know of no separate work on the Azalea and Camellia. Keane's "In-door Gardening" gives weekly directions for their treatment throughout the year. You can have it free by post from our office if you enclose twenty postage stamps with your address.

ROYAL HORTICULTURAL SOCIETY'S SHOW AT LEICESTER (T. Cottman).
—It will be held at Leicester. Advertisements will appear respecting it. You can obtain information from Mr. Richards, Assistant Secretary, Royal Horticultural Society's office, South Kensington.

PELARGONIUMS (*H. J. S.*).—Your Pelargoniums are no novelty. Several of the marbled section, such as *Empress of the French*, the *Duke of Wellington*, &c., have this bad habit of producing abnormal trusses. Caladenia well grown usually produces leaves of the size you mention. (*J. I. jun.*).—Not at all uncommon; too many like it for us to attempt to name it.

PANSIES (*Sarniana*).—There is nothing remarkable in your seedlings. The light variety is the best, but, like all this fancy section of Pansies, wanting in substance. Hundreds of seedlings of the same character are in cultivation.

VINE LEAVES TURNING BROWN (*Hard-up*).—We could not satisfy ourselves that there was anything on the Vine leaf, though in several places it looked as if attacked by red spider. If there is merely the brown watery appearance on the leaves, that will most likely remedy itself. It is generally the result of too much moisture at the roots, and a damp atmosphere inside, which prevents the foliage perspiring freely. Give a little more fire heat in dull weather, and keep the air of the house a little drier.

FLOWER GARDEN PLANTING (*M. Gunzog*).—With your proposed materials we would alter the arrangement thus:—No. 5, place two or three plants of *Tropeolum canariense* against the Plum tree in the centre, and along with it four or five plants of the *Convolvulus major*, allowing these all to run somewhat wildly together, then just one row round of the *Perilla*, pruned to the right height to meet the Brilliant Pelargonium. Amongst the Pelargoniums, at equal distance, have four plants of dwarf *Cannas*, and then your broad edging of *Cerastium* would be effective. With regard to the beds 3 and 2, we would plant them with *Madame Vaucher* Pelargonium, and give a wide verge of *Golden Chain*; 1 and 4 we would plant with a low yellow *Calceolaria*, as *Andrea floribunda*, and give a broad edging of *Lobelia speciosa*; 3 and 2 would be improved with a row of *Purple King* between *Madame Vaucher* and the *Golden Chain*. In fact, a low *Verbena*, purple or mulberry, would be better than the *Golden Chain* unless it do well.

WATERING AND TEMPERATURE IN GROUND VINERIES (*Ura*).—Your Vine in a ground vinery will, after growing freely, require much watering, and if manure water be afforded all the better. If a novice at such watering, place half a peck of superphosphate of lime before watering over the ground where the roots are, and in a fortnight follow with a quart of soot. When a ground vinery becomes too hot a little more ventilation should be given by opening the spaces at the sides more. In a very hot day we would not be alarmed if the thermometer rose to 100° full in the sun below the glass; but it will be as well if it do not rise much above 90°. Shading would neutralise all the benefit of the glass covering. With air constantly, it is amazing the heat a Vine will bear when the heat rises gradually, and there is no confined atmosphere or moist vapour.

MELON CULTURE (*J. T. S.*).—As to Melons and dung beds see "Doings of the Last Week" for two or three weeks past. The plan of the flues will answer, but not well if the furnace is to be above ground. Have it a foot or 2 feet below it. If the flue is to stand on the level of the ground have the going and the return flue in a chamber, covered over with flagstones, slates, or slabs of wood. If slabs of wood be used, place them across roughly, 6 inches at least above the flue, and leave spaces between every two slabs, which fill with brickbats, and then roughly plaster over. On these slabs place soil, and at back and front have openings to let the heat ascend, furnishing them with plugs to regulate the heat at pleasure.

PROLONGING THE FLOWERING OF NASTURTIUMS (*Tropeolums*) (*Flora*).—We have no difficulty in inducing the dwarf *Tropeolums*, as *Tom Thumb*, &c., to bloom all the season, merely by picking extra leaves off and preventing seeding much by gathering exhausted flowers. However, you may plant dwarf *Salvias*, though we do not know which you mean. If the *Tropeolums* do not please, we would plant the *Salvia* or *Scarlet Pelargoniums* at once.

PROTECTING TAGETES FROM SLUGS (*Idem*).—Nothing is so effective for freeing a bed from slugs as going over it before bedtime with the help of a lantern. The next best plan is laying down fresh brewers' grains in little heaps, and gathering the slugs from them early in the morning.

PLANTS FOR SPRING FLOWERING (*Idem*).—The *Alyssum saxatile* sown in the end of July will scarcely bloom early in spring. Sweet and Variegated *Alyssum*, if the latter be kept protected, will do. The *Mule Vink* would also require more time, but that is most to be depended on from cuttings. The *Myosotis*, *Snappdragons*, *Silenes*, *Wallflowers*, and *Stocks* will do well; but the last will need protection in winter.

CLEMATIS JACKMANNI (*C. P.*).—We are unable to explain why the *Clematis Jackmanni* has lost its natural green colour. It may regain it.

ZONAL PELARGONIUMS (*A Subscriber, Glenharvon*).—We could not identify them as you suggest. They are now too numerous and too nearly alike. Those you mention are very good.

CUTTING-BACK MAIDEN TREES AFTER PLANTING—**GROWING WINTER CUCUMBERS** (*H. E.*).—Maiden Peach, Apricot, and other trees planted against a wall in March, should be cut back according to the training intended. If to be trained in the fan-shape we would cut back each tree in the end of March to, say, four buds from the bud or graft, so as to obtain five shoots instead of one, two on each side, and one for the centre, to be cut down next year. Did we mean to make cordons of them we would merely shorten the shoots. You need not despair of the Vines yet, but, of course, much depends on the mode of transplanting. Cucumbers may be grown in winter with bottom heat by means of a flue in a chamber, but there must be outlets under control for letting the heat into the atmosphere of the place, and in that case the flue must be sound. You will do little good without a space between the flue and the earth.

ORCHARD-HOUSE PLUMS NOT SETTING (*C. P.*).—The Plums would not set well in that heat unless air were given—even a little all night.

PEACH-TREE LEAVES BLIGHTED (*A. M. W.*).—The best thing to do with such blighted Peach leaves is to remove them gradually, so as not to injure the tree, and fresh green leaves will take their place. We cannot account for such leaves without knowing more about the trees.

COVERING THE WALLS OF A FERNERY (*E. Z. A.*).—We advise you to cover them with the small-leaved Ivies, both green and variegated. These would thrive and be very handsome all the year round in an unheated fernery. We presume your walls are low, and that plants of compact,

close leaf-growth are required. We recommend *Hedera helix digitata*, minor *Donerailense*, minor *marmorata*, *marginata* *Cullisi*, *marginata* *pulchella*, *tsurica*, minor *lutes*, *chrysophylla*, *marginata* *elegans*, *gracilis*, *marginata* *argentea*, and *aureo-maculata* minor. You may procure the above and the *Golden-edged Ivy* through any nurserymen advertising in our columns.

RADISH CULTURE (*Alice*).—Radishes prefer a rich light soil. The ground cannot be too well dug, and should be broken fine, and a good dressing of very old manure or leaf mould well mixed with it. The situation should be open, and not shaded in the least. To have good Radishes the soil must be well pulverised. The surface should be made fine and the seed sown rather thinly, for if the plants come up very thickly and are so allowed to grow, good Radishes will never be produced. Cover the seeds with half an inch of fine soil. If the weather be dry give a good watering a day or two after sowing, and if the weather continues dry give a watering every evening. If the weather be showery, of course watering will not be necessary. For summer use the Turnip-rooted Radishes are best; the long-rooted are best for spring, early summer, and autumn use.

PRUNING LAURELS (*Idem*).—Your Laurels being large, now would be the best time to prune them, as they would then have an opportunity of making a good growth this season. If they are not required to be cut-in much, the best time is early in June, and go over them again in August, shortening all irregular growths.

REMOVING THE FLOWER STEMS OF ARUMS (*Idem*).—The flower stems of Arums and all plants should be removed as soon as the flowering is past, unless seed be wanted, then, of course, they must remain. Allowing the flower stems to remain only weakens the plant.

PEAR TREES UNFRUITFUL (*O. C. G.*).—We are unable to account for your Pear trees being unfruitful, the aspect being good. We presume they grow vigorously. We would stop all the shoots on the principal branches at the fourth leaf, except the leaders of the branches, which must not be stopped at all. Take out the points when the shoots stopped have made three leaves, and continue to do so throughout the season up to September, after which stopping must no longer be practised. We would further, towards the end of October, take out a trench round each tree, 3 feet from the stem, and work under the ball, cutting off all roots that go down deeply, removing the loose surface soil with a fork, and in this way proceed until the tree could be lifted, preserving as many of the fibres and small roots as possible, and allowing as much soil to adhere to them as they would carry. We would then lift the tree, clear out the soil to a depth of 2 feet, give the bottom of the hole a slight inclination from the wall, and place on it 3 inches of lime riddings, or equal parts of lime and coarse gravel mixed so as to resemble mortar. After ramming hard we would put on another layer 1½ inch thick, and make very firm with a wooden rammer. Place on this 6 or 9 inches of brick and lime rubbish from an old building, the older the better, and on that a layer of turf, grass side downwards, then a few inches of chopped sods, on which place the tree, spread out the roots and place soil amongst them, not covering the uppermost roots deeper than 3 inches. The soil may be the top 3 inches of a pasture on a rather strong yellow loam, and should be chopped rather fine with a spade. Each tree will stand on a small cone, and the ground will slope from the tree outwards. Secure the branches to the wall, give a good watering, and place 3 inches thick of fresh stable litter round each tree as far as the hole extended. The trees are best lifted just when the first indications of the leaves falling appear. Cut-in all the side shoots or laterals, whether stopped or not, in November, after the leaves have fallen, to within half an inch of their base, leaving the spurs entire. We would advise the same treatment to be continued in the following year, only a few good waterings should be given in spring and early in summer, and the lifting must, of course, be omitted. We think you may be sure of a good crop within two years, and you will have more in one season from your present trees than you would in half a dozen years were you to root them up and plant trees on the Quince. The Pear on the Quince stock is very productive, comes into bearing early, and produces fruit of fine size and quality. We grow trees so worked largely, and have planted a tree of them between every two permanent wall trees, which last are on the Pear stock, and are what we recommend for walls of greater height than 10 feet. On lower walls the Quince stock is best, and the Quince has the advantage of succeeding in soils where the Pear does not thrive. Some sorts of Pears do not succeed on the Quince well, and of those you name, *Jargonelle* does not succeed so well as many others, but *Duchesse d'Angoulême* does admirably. The Quince is the best stock for inducing early productiveness in Pears worked upon it.

DIVIDING IXIAS (*S. H.*).—It is now too late to divide the roots of *Ixia*. It should be done at the time of repotting, the plants being left undisturbed in the pots after the foliage decays until the time of repotting. The balls of earth being then carefully broken, the bulbs can be dressed and divided without injury. October is the best month to perform this operation, the earlier in the month the better.

PLUM, PEAR, AND APPLE LEAVES INJURED (*A Ten-years Subscriber*).—Your specimens exhibit unmistakable evidence of the injury resulting from the cold nights on the early vegetation we have had this season. We cannot advise a remedy. Yours is not a solitary case, trees never promised better. Our neighbours complain of their fruit prospects; their trees are damaged by cold followed by swarms of aphides. The way to destroy them is to syringe the trees, and whilst wet to dust them with tobacco powder, which should be forced on the under as well as the upper side of the leaves, there being distributors on purpose.

CAMELLIAS INFESTED WITH APHIDES (*Idem*).—Dust the plants lightly with tobacco powder, and wash it off within three hours, wetting the plants before dusting. The tobacco powder will destroy the aphids within an hour. The tobacco was not good, or the house was not sufficiently filled with smoke, otherwise the insects would have been destroyed. As the leaves are sticky we would advise your washing them, as well as the shoots and branches, with a sponge, using a solution of soft soap or Gishurst compound at the rate of 4 ozs. to the gallon of water, as we think you have scale as well as aphides.

REPOTTING CAMELLIAS (*Idem*).—Now is a good time to pot *Camellias*. Do not disturb the roots much. We prefer, however, to repot earlier—immediately after the flowering is over. If done now give a slight increase of heat, and a moist atmosphere with shade from hot sun.

GREEN FLY ON PEACH TREES (*A Lady Gardener*).—The best remedy is to dust the trees with tobacco powder. They should first be syringed

and made wet, and then the powder should be forced with a distributor upon the under side of the leaves as well as over them. It is not well to syringe the trees when in blossom, but a slight wetting will not do any harm. The trees should be dusted with the tobacco powder upon a calm day, and in the evening. One good dusting will be sufficient if it be effectually performed, or so as to reach all the insects, for the tobacco kills all it touches. The trees may have a good syringing with water any evening within a week. The dusting may be practised as soon as the trees have set their fruit. A little fire heat may be afforded your recently lifted Vines during cold dull periods throughout the summer, avoiding a dry atmosphere. They cannot be too gently excited.

CALCEOLARIAS FAILING (*A Constant Reader*).—We entirely disagree with you as to the disease being occasioned by putting the cuttings in cold frames. We remember the time when Calceolaria cuttings were invariably inserted in pans, struck, and wintered in an airy greenhouse. There was even then the Calceolaria disease, and it has only shown itself more of late years from the greater number grown. It certainly is many years since Mr. Fish first propounded the practice of wintering Calceolarias in cold frames. It is a practice we have followed for many years, and with the best results. Our practice is very simple. We make ready a place in a sheltered open situation, putting a few inches of lime riddings on the ground and ram quite hard. Worms do not come through that, and we then set the frames on bricks laid flat. Coarse gravel is then placed all over the bottom to the depth of 3 inches, and next an inch or two of coarse compost, and 3 or 4 inches of finer, which consists of two-thirds loam and one-third leaf mould, and then from 1½ to 2 inches of rather coarse sand. The cuttings are put in 1½ inch apart every way,

a good watering being given. Ashes are placed against the sides of the frame all round, plenty of air is given in mild weather, and protection is afforded from frost. Early in March if the weather is not frosty, the points of the cuttings are pinched out, and in the beginning of April we make trenches as for Celery, only 4 feet wide, with 3-feet alleys between them, and put in plenty of well-rotted manure and leaf mould, mixing these materials well with the soil. The plants are planted in rows across the beds, 6 inches apart from row to row, and 3 inches from plant to plant. A good watering is applied, and then water is given sparingly for a time until the plants are growing freely, when abundance is afforded. They are protected from frost by old lights or mats resting on spars placed across the trenches. The first week in May the plants are again stopped, and we have dwarf bushy plants and so strong that any one would make a dozen such as you enclosed to us. Your plants are drawn, weak, and badly rooted, and never will make good plants.

GRAPES SEVERELY SPOTTED (*C. S.*).—The berries were not sufficiently thinned. Cut out every berry that shows a spot, and thin away one-third of the remainder. The roots of the Vines are sluggish, they should be kept warmer, be watered with tepid manure water, and the house freely ventilated.

INSECTS (*Howarth Ashton*).—The bee sent is one of the Andrenidæ, or short-tongued bees (*Andrena ciceraria*), which make their nest by burrowing in sandy places in the spring. They are solitary in their habits of nest-making, although often found flying together in numbers over the spots they have selected. (*Subscriber, Beaminster, Dorset*).—Your small, red-spider-like insect is one of the mites, *Trombidium holosericeum*. It is quite harmless, feeding upon more minute insects.—W.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending May 5th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

REARING CHICKENS.

I WAS much pleased with "Nemo's" communication in the number for April 16th, and beg to tender him my thanks for the instruction imparted; but in concluding his remarks about the chilling of eggs, he says, "In cold weather half an hour off the nest is too long, though double that time will not kill the chicks in the eggs in May," clearly showing that even "Nemo" does not attend to his sitting hens so well as he might. This has led me to suppose that many, though thoroughly understanding poultry, do not so thoroughly understand rearing, and do not carry it out systematically.

In the directions I am about to give I do not claim the merit of originality. The method is due to M. Jacque, the editor of "Le Poulailleur," but having fairly tried it against the natural system I can testify to its great superiority in many respects. Its advantages are a greater average of chickens from a given number of eggs, more robust chickens as a rule, a more equal number of chicks to the several mothers, and lastly, little or no distress to the hens.

I must state before entering into detail, that my poultry-keeping is carried on in the middle of a town with a population of thirty thousand; it is not, therefore, pursued under the most favourable circumstances.

When a hen takes to her nest she is the same evening removed from the yard to a (sitting) room, into which only a half light is admitted, and there kept on dummies for a few days until two or three hens are broody. I prefer three or more to two. They are placed in separate covered hampers 2 feet long and 1½ foot wide, in which clean new hay has been spread. Each basket has attached to it a linen label bearing the date of sitting, the name of the hen, the number of eggs, with the date upon which chickens are due, thus—

BETSEY.—February 29.

14 Hondans,

Due March 20.

also a clean piece of old flannel.

Every morning at the same hour each basket is opened in turn, the hen taken out and placed under a coop, being previously supplied abundantly with food, both soft and grain, and with clean water. Fifteen minutes, neither more nor less, are allowed for feeding. Whilst the hen is off the nest the eggs should be kept covered with the piece of flannel, and having put all the sitting hens to feed, each nest should be visited in turn to ascertain that no casualties have occurred; and if any eggs have been broken turn the rest out, put in clean hay, and cover up again as quickly as possible.

On the sixth day the hens should have an extra ten minutes allowed them, and should be given an opportunity of dusting themselves whilst the eggs are being examined for chickens, which is done by enclosing a lighted paraffin lamp in a box, in one side of which a hole about the size of an egg has been made. To this hole each egg is applied in turn, and returned to the nest or rejected, as it proves to be barren or otherwise. This should be done in a dark room. When a great proportion of the eggs turn out barren, a complete sitting should be made up to one or two of the hens, and the rest kept upon dummies for a few days till a fresh set of hens is ready; hence the greater the number of hens put to sit on a given day the greater the convenience.

On the twenty-second day the baskets containing the hens and chickens are brought to the light, the chickens reckoned, and regularly distributed between the hens. Some bread crumbs for the chickens, and grain for the hen, are put in a saucer at one end of the basket, and the whole taken back to the half light till the twenty-third day, when they may be turned out where it is intended to rear them.

The above directions may seem complicated and unnecessary, but in practice will be found to facilitate the work, prevent many mishaps, and, consequently, increase the percentage of chickens, whilst the mothers will turn out with their broods much less exhausted, and consequently better fitted to take care of them, than if left to sit closely for several days, as many, and those the best sitters, frequently do, and then get up and stay off the nest for half an hour or an hour, which, if it happen to be a cold day, may spoil the eggs or make the chickens weakly.

I trust "Nemo" will not feel offended at my seizing upon this part of his well-written article, and hope he will point out any error I may have unwittingly fallen into. I inferred from his remarks that chickens were not so numerous as usual this season; I as yet see nothing exceptional in the chicken season. These are the results of my attempt so far:—Five

mothers are now rearing fifty-four chickens; many deaths have already occurred, some of the broods being six weeks old, but the numbers stand as above this day April 28th, 1868.

Buckwheat is here the favourite food with both adults and chickens. When mixed with other seeds, such as oats, wheat, and barley, it is invariably picked out first.—*VERITAS, Turf Bank, Jersey.*

GAME FOWLS.

I THINK "NEWMARKET's" remarks in reference to the good points of Game fowls are somewhat prejudiced, and contrary to the generality of modern ideas. It is possible he will admit that birds exhibited now by a few of our most noted breeders of Game fowls are very far superior, both in feather and other properties, to birds of former periods, are bred generally with more care, and, I believe, are as deep game as those bred when cock-fighting was in its zenith. Well-matured progression in the art of breeding is the only safe way of arriving at perfection, and not adhering so closely to old practical theories. The high position our shorthorns, our race horses, pointers, and greyhounds have attained has resulted from the spirited and energetic efforts of breeders, who have discarded the "rest and be thankful" maxim. Breeders of this class well deserve the thanks of the public for the improvement of our breeding stock.

I do not agree with "NEWMARKET" as to the inferiority of our present Brown-breasted Reds in comparison with the old gipsy-combed birds. I consider the present race of birds far superior, both in feather and other points. The dark-bodied hens, also, when slightly streaked with red on the breast, are far handsomer than the brown-bodied hens. They also breed very true to colour, are as game, and quicker fighters. The old Shropshire Brown Reds, were, I believe, a very slow bird, but a cross of the Pile, Black-breasted Red, or Duckwing, has produced quicker fighters, brighter and richer in feather and face, nor have they suffered deterioration in other respects.

My only objection to birds of the present day is whenever there has been a tendency to produce undue size or legginess, and I fancy this fault is fast fading away. The judgment at Leeds, Halifax, and other places, has for the most part been in favour of birds of quality, independent of great size, and this is as it should be. I do not advocate the interests of every small bird, nor do I wish to see undue size take precedence.

In regard to "NEWMARKET's" remarks as to the colour of legs, I think his opinions have changed since 1857. It he will refer to *THE COTTAGE GARDENER* of that period, volume xvii., page 372, he will find the following passages in one of his own articles, "I cannot agree with him (alluding to another correspondent), in liking white or blue legs for any variety of Game fowl, they being too much like the common barndoor fowl, the legs of which are nearly always white or blue. I consider a bright yellow-legged black-breasted red cock to be the perfection of a Game fowl. I myself like to see the skin yellow, but then the flesh is invariably white, I fancy the yellow-skinned birds are the fiercest." "Again, in volume xviii. of the same year, page 125, the following passage occurs. "As to legs I cannot change my opinion, and would not keep a white or blue-legged Game fowl . . . I must agree with 'W.' that white legs do give a soft appearance to Game fowls."

My own opinion is that all light-coloured birds should have yellow legs, these harmonising best with the different shades of colour, the darker birds always legs of a darker hue; but I would not say that the colour of the legs has any influence upon the fighting qualities, although a few old cockers are still favourable to white-legged birds. I feel no hesitation in saying, that if I were to canvass the opinions of different breeders and keepers of Game fowls I should have a majority in favour of the whip tail. I also think that it would be absurd in me to assert, that the form of tail had any directive influence upon their courage. Some people are opposed to the slightest innovation, nor will any enlightened precedent induce them to acknowledge any improvement established by those who are eminently distinguished for their abilities through repeated intercourse with those following the same avocation.

In regard to the Black-breasted and Brown-breasted Reds, these were never bred to more perfection than at the present time, nor do I think the Black-breasted Reds have been judged with more care and correctness than other kinds. Perhaps they may have been a little more popular of late. Duckwings, Piles, and other colours have not so generally maintained their position so well, although occasionally we see some excellent

birds. Perhaps I shall not be open to contradiction if I state that the present breed of Game fowls owes a great deal to the Malay cross, which has given the birds a loftier and more majestic appearance, with a longer neck and head, and finer carriage. The coarseness and wartsiness has also been softened and toned down by judicious crossing. Birds of this class surpass in general contour the old style of Game fowl for exhibition purposes.

"NEWMARKET" will find a good article, signed "W. H.," on the points of Game fowls in volume xv., page 324.

I have been particularly fortunate this season in breeding, not having had a single case of last year's malady, although I have bred principally from the same stock and in the same yard. I have a few hatched in the second week in January, a few hatched in February, March, and April, all fine, healthy, well-grown birds, equal if not better than May or June chickens. A friend of mine, who lives a few miles from my place, has lost a large number this season, although he had not a single case last year. When the weather has been unfavourable I have placed them in a large horse box, lighted from the top, and 4 or 5 yards square. The floor I have covered to the depth of 3 or 4 inches with clean soil and sand; over this I have littered clean sweet straw, and when I serve with corn I scatter it amongst the straw, thus affording amusement for the old hens and the young broods, and I believe so conducing to their well-doing.—*YORKSHIRE.*

THE SELLER OF BOILED EGGS.

HAVING only just seen the *Journal* of April 16th, I wish to inform "Nemo" that my object in sending an account of the boiled eggs was simply that others might be led to examine any they might suspect to be in the same state, it being a new dodge to me to boil eggs for sitting. It could not be, as "Nemo" infers, with the object of getting the money returned, for on detecting the fraud I wrote by first post to that effect, demanding my money back, and giving the seller only one day to do so, or it would be put in other hands and proceedings taken against him. The seller thought, no doubt, it would spoil the egg trade for the future if he did not comply; I had, therefore, the money before anything appeared in the *Journal*, and though he may this time have escaped the legal, it is to be hoped the "moral kick" will act in a salutary manner.

I would, however, beg your readers to be on their guard if ordering an "honest sitting" of eggs, which the seller said I might have, more especially if from the neighbourhood of Halifax, without having the fowls sent to lay them a sitting at their own residence, which the said seller of boiled eggs offered to do if I would only send him the eggs back that he might judge for himself! Mark the craft. He wanted the proof of his fraud returned safe into his own hands, and for what? so that he might put "his man" in prison!—*J. L. L.*

CAUTION TO PURCHASERS.

In a recent number of your paper I advertised for Egyptian Geese, and on April 6th I received a reply from W. D. Woodward, giving address 198, Essex Road, Islington, London, N., offering me one or a "couple of pure-bred Egyptian Geese, just beginning to lay, at 9s. each. If you send P.O.O., be good enough to let it be made payable at the Islington district office."

I naturally thought this price very low, and made inquiries from my business correspondents, and found that no such person was known at 198, Essex Road, Islington, which is a post-office. I have since inquired at 198, Essex Road, Islington, and find that no such person lives in the neighbourhood.—*ALBERT O. WORTHINGTON, Newton Park, Burton-on-Trent.*

DUCKS PRODUCING EGGS FERTILE

WHERE THERE IS NO WATER FOR THEIR SWIMMING.

In spite of the general opinion that the eggs of Ducks which have not access to water are unfertilised, I tried a sitting from my own, kept in a stableyard with no water, except for drinking, and am glad to state that every egg has brought forth a duckling. So much for popular notions.—*W. D. A.*

EXCESS OF LAYING BY DUCKS.—The following instance I cannot but think is an extraordinary freak of nature, and worth

recording in the columns of "our Journal." During the night of Sunday, the 19th ult., my three Ducks laid four eggs of the usual size, one with a double yolk, and one soft egg, in all six eggs. On more than one occasion I have known them lay four eggs in one night. I also found that my three Ducks laid four eggs during the night of April 21st. I should state that they did not lay on the night of the 20th.—JOHN GOULD.

[Such excesses and irregularities always indicate that the birds' egg-system is over excited. The Ducks probably are excessively fat.—Eps.]

NEWCHURCH POULTRY SHOW.

THIS Meeting, held April 29th, was favoured with dry weather, and the attendance of visitors was extraordinarily good; but the hurricane that prevailed on that day was a very great disadvantage, for tents succumbed to its fury, and ladies had to cling to each other to avoid being blown down. To the general appearance of the poultry exhibited the wind, of course, was a very considerable drawback, and naturally those pens that happened to be placed in its direct course suffered most severely; but in many instances the exhibitors covered their pens of poultry to prevent evil consequences, and this proceeding, of course, diminished the attractions of the Exhibition. The now by-far-too-common mistake of waiting for some hours beyond the time specified for the birds to be penned, to take in the late arrivals, caused considerable difficulty, and is, beyond question, one of the features of many of our agricultural shows that loudly calls for improvement. An hour duly kept, and undeviatingly insisted on, is by far the preferable plan to ensure permanent confidence. Some of the birds in this instance did not arrive till many hours after the opening of the Show. The public sale on the Show ground of catalogues for some hours prior to the adjudications being even commenced, is another objectionable feature, and one that calls for alteration. The pens, and the attention shown the poultry, need but little remark, being really as good as could be fairly expected, and we can with confidence state the character of the poultry generally was of the best description in almost every class throughout the collection.

SINGLE COCKS.—*Gama*.—(Any colour).—First, W. H. Wheeler, Carlton near Nottingham (Black Red). Second, C. W. Brierley, Middleton, Highly Commended, W. Westwell, Baxenden, (Brown Red); J. Turner, Radcliffe; W. Morris, Accrington, (Black Red). Commended, J. Rowncs, Scout. *Bantam*.—First, J. Bamber, Accrington. Second, S. W. Smith, Carlton, near Nottingham. Commended, C. W. Brierley; W. A. Taylor, Manchester.

GAME (Any colour).—First, J. Bowness. Second and Highly Commended, C. W. Brierley. Highly Commended, J. Turner.

GAME BANTAM.—First, J. Robinson, Folesworth, near Manchester. Second, T. Birtwistle, Makengate. Highly Commended, G. Birtwistle, Makengate; G. Anderton, Accrington.

BANTAM (Any other variety except Game).—First, T. Burgess, Brighouse. Second, S. & R. Ashton, Mottram. Highly Commended, G. Anderton; W. A. Taylor.

DORRINGS (Any colour).—First, J. Stott, Healey, near Rochdale. Second, J. Robinson, Garstang.

COCHIN-CHINA (Any colour).—First, F. Haworth, Rawtenstall. Second, W. A. Taylor (Buff). Highly Commended, J. Robinson; T. Bott, Woodlands, near Bury. Commended, L. Duckworth, Sheep Hey, Ramsbottom (Buff).

SPANISH (Any variety).—First, H. Wilkinson, Early (Black). Second, W. A. Taylor (Black). Extra Prizes, J. Newton, Silsden, near Leeds. Highly Commended, J. Ashworth, Heightside, Newchurch (Black).

BRADIA POOTRA (Any colour).—First and Second, E. Leech, Rochdale. Commended, W. Hargreaves, Bacup (Dark).

HAMBURG (Golden-pencilled).—First, H. Pickles, jun., Early, near Skipton. Second, S. Smith, Northowram, Halifax.

HAMBURG (Silver-pencilled).—First, W. Wilson, Crawshawbooth. Second, T. Sharples, Crawshawbooth.

HAMBURG (Golden-spangled).—First, S. & R. Ashton. Second, H. Pickles, jun. Highly Commended, N. Marlow, Denton, near Manchester.

HAMBURG (Silver-spangled).—First, J. Fielding, Newchurch. Second, H. Pickles, jun. Highly Commended, J. Fielding.

ANY OTHER VARIETY.—First, Col. Stuart Wortley, Grove End Road, London (Crevin-Coeur). Second, H. Schofield, Newchurch (Black Hamburgs). Highly Commended, D. Lord, Stacksteads (Black Hamburgs); N. Marlow; H. Woodworth, Church, near Accrington.

TURKEYS.—First and Second, E. Leech.

GESE.—First, E. Leech. Second, Mrs. Tattersall, Scout, Newchurch.

DUCKS (Aylesbury).—First, Withheld. Second, R. Whittaker, Flaxmoss, near Haslingden.

DUCKS (Rouen).—First, E. Leech. Second, T. Bott. Commended, J. Greenwood, Burnley.

DUCKS (Any other variety).—First and Second, W. Brierley. Highly Commended, S. & R. Ashton (Carolina).

The Judge was Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, near Birmingham.

CHILLED EGGS—PROTRACTED PERIOD OF HATCHING.

I HAVE this season had one or two rather remarkable instances of eggs hatching after having been left some hours cold, and beg to send you the particulars, in case you think

them worth a corner in your columns. Some breeders affirm that it is most important to have the eggs closely sat for the first few days. Others think that the critical time is a few days before hatching. Which theory is correct? or is there anything in either of them? On March 21st I sat a Game hen on fifteen Brown Red eggs. On March 30th she was accidentally shut off the eggs from eight until one o'clock, and on April 11th and 12th hatched out nine healthy chickens. On April 20th I set eight Brown Red eggs under a Game Bantam hen, and she was shut off the eggs from seven o'clock on the night of the 23rd until eight o'clock the following morning. I have to-day (May 2nd), broken one of the eggs, and found a live chicken about two-thirds formed. This is the most extraordinary instance of the kind I ever knew, especially as the night of the 23rd of April was frosty, and the nest in a tub out of doors.

On April 7th, forenoon, I sat a hen on fifteen eggs, and a few days afterwards found that she was infested with parasites. I fumigated the box in which she was sitting, and dusted the hen well with quicklime, which made a thoroughly effectual cure, but the eggs did not begin to hatch out until April 30th, and the last chick was hatched at noon on May 2nd. Is it not very unusual for eggs to hatch four days after time? and could it have been caused by the hen not sitting closely the first few days in consequence of the parasites?—BROWN RED.

ON THE REARING OF TURKEYS.

Your insertion of my notes on the rearing of spring chickens has led me to send a few more on the rearing of Turkeys.

Turkeys being rather delicate should never be bred from near relations. Procure the cock and hens from different places if possible. The first eggs laid by the hen Turkey should be placed under a common hen, and let the hen Turkey lay a second clutch. It is best to hatch all that are required not later than June.

The Turkey hen is a good sitter, and while kept in the coop a careful mother. She must never be let out early in the morning with her brood, otherwise she will drag them through the wet grass, and tire and exhaust them. Stinging nettles, too, should not be left in their way, as they sometimes get their legs stung.

The coop should be kept in a sheltered situation, with its back to the wind, and be moved every day. The ground on which coops are placed will soon become tainted.

For food I use curds mixed with meal, bread soaked in ale, bread crumbs, and a little canary and hemp seed, but the last must be used sparingly. I do not like the plan of keeping the food always before them, but think it best to give a certain quantity at a time, and fresh. A little well-cooked meat, torn into shreds, is very much relished, such as remains after beef tea has been made. They do not care much for wet food, such as meal, but require a change until they come into the yard and eat corn with the other poultry. I never give any green food to young Turkeys, but let them run on grass. I have had them in a garden while the hen is cooped, and they are very fond of cabbages. I do not approve of poultry under cover, unless for a day or two. If they will not do well out of doors, neither will they in-doors.

When the young are about two months old they must be carefully attended to, as this is a very trying time for them while they are "shooting the red," or getting the red head. When they are old enough to run with the other poultry they must be driven in at night, otherwise they will frequently roost out of doors and take cold.

The cocks may soon be distinguished from the hens by their strutting, spreading their tails, and lowering their wings. The hens spread theirs also, and lower their wings, but, from my own observation, only while challenging for battle, neither do they raise the feathers so high as the cock.—L. E.

A FEW REMARKS ON THE DIFFERENT VARIETIES OF PIGEONS.

I now proceed to give my opinion on some other varieties of the domestic Pigeon, with reference to their present condition as exemplified by those exhibited.

I shall pass by the Pouters, so much having been written on that particular breed of late in "our Journal" by such able

and well-qualified writers on the subject, and who have justly earned the thanks of the Pouter-fanciers in general.

Carriers seem evidently to be still in good hands, for many of the birds exhibited last year were as fine in quality as any that I had hitherto seen; excellent in colour—erect, yet graceful in their carriage, and with splendid wattle and eyes, leaving scarcely anything to be desired, with the exception of a little more variety of colour. The Blues and Whites, though good, being very few, would it not be well for some good fanciers to look after these colours, and breed them before they are entirely lost? It would be a real boon to this particular fancy.

Barbs, I also think, fairly maintain their position, with the exception of the Whites, of which colour I have seen much better specimens; and I think the Yellows are a little on the decline, no birds last year coming up to Mr. Eden's celebrated birds of a few years ago. English and Antwerp Dragons are still strong in numbers and good in quality.

In Jacobins there is a great falling-off. Where are such as the splendid birds of those excellent old fanciers, Messrs. Bowler, Wicking, Maddeford, Cottle, and some others, particularly the strain of the first-mentioned gentleman? They were the produce of many years of careful and thoughtful breeding; lengthy in feather, short-headed, down-beaked; of fine, rich, deep colours—Yellows, Reds, and Blacks—with frills, such frills, that looked at in profile they nearly hid the eye of the bird from view—not as now in very many cases, the feathers of the hack part of the head either cut or frilled out to make the hood lay even and well over. Even then they are deficient at the sides, very often not reaching to the eye, and standing away from it; besides which, whatever exhibitors may think of their birds so trimmed as they often appear in the pens, it does not make them better birds, nor are they any better than a sham and a cheat; and should they thus obtain a prize, they must remember that they have come by the same unlawfully. No true fancier will do this, but will by patient endeavour so breed his birds that they shall have in a greater degree those points naturally which he of less tender conscience tries to obtain by artificial means.

The perfect Jacobin ought to have its frill lying well and closely over the head, also close and flat to the cheeks, reaching at least partly over the eyes, and meeting in front of the breast just below the beak. This quality I observed in scarcely any of the birds exhibited last year, nor were they, with few exceptions, so good in colour as formerly. The heads were very variable in form, not a few being of the Tumbler shape instead of having, as I have before noted, the peculiar short, square, down-beaked formation of this elegant variety. Many of the birds also had orange eyes.

The breed has, as far as I have seen it of late, deteriorated; and this is much to be lamented, as it will take years, even in good hands, to reproduce its former excellence.

In my last article, "gold-lined beak" should have been "Goldfinch beak;" and "have not colour in the tail" should have been "have ash colour."—HARRY.

THE POUTER CONTROVERSY.

WILL not some fancier come forward and give us information with regard to the Pied Pouters? The Pouter being the favourite of the Scotch fanciers, and they having done more than any other breeders to bring that beautiful bird to its present state of excellence, they doubtless have felt themselves aggrieved at the tone of some of the letters which have been published, therefore have written rather warmly in reply.

Thanks to "HARRY" for his letter, and I hope he will proceed and do as he has offered at once; then possibly we shall get a controversy on every variety of Pigeons. If it is not asking too much of our ardent fanciers, would it not be interesting if some would take notes of the doings of half a dozen pairs of their birds, and publish those notes at the end of the breeding season, stating what they did in the shape of markings, colour, &c.? Cannot a fancier be found to come forward for every variety of birds? Could not a volume of knowledge be revealed worthy of a young beginner's study? Possibly some may think that it would be treading everybody as much as he knows himself. What if it did? Would it not show him to be anything but a selfish fancier? What an interesting paper could be formed by those that make the "any other variety" class their favourite pets! What could be said on Satinets, Fairies, Ice, Spots, Swallows, and many other varieties! Any one at the last Birmingham Show, and fond of sportive-coloured

birds, might have stood for any length of time and admired the recently-imported German Toys with their brilliant colours. Far are the Germans ahead of us in colour.

I will now say I differ from Mr. Volckman on the Carrier. Were not the prize and many of the other Blacks all that could be desired for colour at the late Birmingham Show? Most certainly so, in my opinion.

Mr. Volckman asks how many times the Black may be crossed with the Dun. I think that question cannot be answered, because I never knew of any Blacks that have not been crossed with Duns. Do you ask, Why have the Blacks been crossed with Duns? In my opinion the reason is this—you invariably find developed Duns coarser-headed, heavier-wattled, larger-eyed birds than Blacks: therefore they have been matched to Blacks, the consequence being far better points in the head, wattle, and eye, and bad colour, which may be remedied in one season's breeding. Whilst speaking on the Carrier, let me ask the fancy now that there is a separate class for Blues at some of the principal shows, to study their colour (which is bad), rather more than they have done.

I certainly coincide with Mr. Ure, that the Birmingham Show has made rapid progress within the last few years, there being better birds and larger entries in all classes. Of course in all shows we shall meet with some indifferent specimens, for the want of proper information respecting the merits of birds on the part of their owners; yet, taking the prize birds throughout the show, in my opinion there is a decided improvement in every class.—A YOUNG FANCIER.

ALMOND TUMBLERS.

I MUST say that I entirely disagree with "HARRY's" remarks on the Almond Tumbler. He seems to think that the true Almond Tumblers have deteriorated in many of their qualities of late years. Now, I have kept them for some years past, have been among them as much as any man for the last nine or ten years, and I have seen the Birmingham, Crystal Palace, Glasgow, and most of the leading shows, and from what I have seen, I certainly must say (with all due deference to "HARRY"), that I am quite of a different opinion, and that to me there is a great improvement in them; for instead of birds with faces seven-eighths of an inch in length, as formerly laid down in the rules of an old society, we have plenty now little over five-eighths, and with other properties equally good.

As to colour and marking, if "HARRY" had been lately to some of the private London shows, where he talks about having seen them "years ago," he might still have seen them. The fact is, "HARRY," like many others, having once seen a few birds to their own liking, without taking the trouble to look about them, run away with the idea that there can be no others like those they once set their minds on; and should "HARRY" or any other gentleman wish to see some really good Almond Tumblers, they have only to pay a visit to the City Columbarian Society.—J. FORD, Hon. Sec.

UNJUST SLAUGHTER.

I was sorely tried and puzzled yesterday. It was a fine day, so I looked into No. 3 nucleus box to see how matters were coming on; and as I found only a small company of workers along with the queen, and she was laying eggs fast, I took out of my pure Italian stock the ripest brood comb I could find, and placed it with the adhering bees in the nucleus to strengthen it. All seemed right, but two hours, or not more than three afterwards, I went to look, and lo! the alighting board of the stock—a good-sized one—was covered with bees in a state of excitement, and they were slaying some bees on their attempting to enter, by dozens.

How is this? Have the bees from the brood comb returned to their parent hive, and has their temporary absence of two to three hours been looked upon as an act of high treason and resented as such? It seemed a hard case if capital punishment was to be inflicted for such an offence; but it seemed as though such was really the case, as there seemed no addition to the number of bees in the nucleus. So to make matters as well as I could I fed them in order to quicken them up a little. I cannot see that I did wrong in removing the brood comb with the bees on it; but if there is no amendment in the nucleus I must do something to strengthen them, or I may lose the

queen, and although she is a "doubtful" one, she breeds very well-marked Ligurians.—J. R. J.

[It is certainly strange that bees should be slaughtered on their return to their parent hive after so brief an absence. It may possibly be accounted for by the supposition that they carried with them the odour of another stock, and were therefore treated as strangers. We know that a similar hypothesis has been advanced in respect to queens destroyed by their worker sisters on their return from a wedding trip. You ran a great risk of losing the queen by introducing the adult bees which adhered to the brood comb, and we should advise you by no means to repeat the experiment. If the bees in the nucleus are too few to cover and hatch out an additional brood comb, we should exchange one of their own for another and a ripper one from a strong stock. In very extreme cases we have sometimes spent hours in picking off one by one, and dropping into a tumbler covered with the pitfall-like top of an invalid's expectorating cup, some hundreds of grey young bees from the combs of a strong stock in order to add them to a nucleus. Such bees will not attack a queen, and must perforce remain permanently attached to the colony to which they are transferred.]

HOW TO BREED PURE QUEENS—IMPORTANT DISCOVERY.

I wish to call the attention of English bee-keepers to a most important discovery made by M. Koehler, a Protestant minister in Hesse. It is no less than the secret of directing the breeding of the bee; so that, as with our cattle, we may select the choicest male to be the father of the future stock. The discovery would appear almost too wonderful to be true, but its value and reality are vouched for by some of the leading bee-keepers in Germany.

Mr. Koehler will communicate his discovery upon a promise, on honour, of strict secrecy for the present, and a fee.—HENRY DE ROMESTIN, *English Chaplain at Baden.*

[Mr. Koehler's process having been communicated to me, I can state that it is simple and perfectly feasible. It has, moreover, been tried by some of the leading apiarians in Germany, who have publicly testified to its success. I have not yet had time to test the discovery myself, but as it is in strict accordance with the instincts and habits of the insects, I have no doubt whatever of its effecting the desired end.

At the request of Mr. de Romestin I have consented to receive the names and addresses of those who may be desirous of becoming acquainted with Mr. Koehler's process. All applications must be accompanied by a promise of secrecy and a post-office order for 10s. 6d. fee and postage, in return for which printed instructions will be forwarded. Any one requiring an immediate acknowledgement of their remittance should also enclose a stamped and directed envelope.—T. W. WOODBURY, ("A DEVONSHIRE BEE-KEEPER"), *Mount Radford, Exeter.*

PROCURING ARTIFICIAL SWARMS.

I SHALL be glad to know if the following plans will answer—
1st. Put a frame, having a queen's cell from a Ligurian hive and its accompanying bees, into a hive, and put it in place of a black stock. Will the Ligurians inside and returning black bees quarrel? I presume drone comb will be built at first, which I would remove when the young Ligurian queen begins laying. I ought to mention I have no worker comb to give the bees at first.

2nd. Fit comb from an entire colony into frames, having a Ligurian queen's cell in the centre one, all rival cells being cut out, and put this hive in place of another black colony. Will the returning bees raise the Ligurian royal embryo?—C. A. J.

[Either of the above plans are likely to answer, but it would be well that the comb should contain pure Ligurian brood in all stages, as well as a royal cell or cells in case of the latter happening to be torn out by the returning bees during their first excitement or discovering the change that has taken place.]

FRAME HIVES.

I SEND you a frame such as I use, and think it simpler than those I generally see drawings of in "our Journal." I have others made with a bead in the centre of the frames, and find

it a great guide for straight comb-making. It simply consists of a small strip fastened on with three tin tacks.

The method of fixing the combs in frames could, I think, be more easily done with indiarubber bands. I used them last year, and found them very handy, especially if you are transferring bees from a straw hive to a Woodbury, saving time, too, as you get them into their new home at one operation.—J. J. S.

[Your frame is similar to those ordinarily used, differing somewhat in its mode of construction by being dovetailed instead of morticed at the top, whilst the bottom rail rests in a notch at each end, and is further secured by copper wire. These frames are stronger and more simple than the "compound" ones used by Mr. Woodbury, which, however, possess, as he believes, some special advantages. The idea of using indiarubber bands for the temporary support of combs is new to us, and appears a good one.]

SILKWORM-REARING IN ENGLAND.—No. 9.

WHAT preparation do silkworms' eggs require before hatching? It is customary with a wooden knife or metal spoon to scrape them from the linen on which they were laid, after soaking it in pure soft water about twenty minutes, to soften the gum, causing them to separate easily. This operation is best performed in autumn, or not later than the beginning of March, before the worms begin to develop in the eggs. The eggs are afterwards washed in water, moving them about gently with the hands, and separating those which stick together. After a few minutes the best and heaviest will remain at the bottom; and the inferior and light, floating on the water, can be poured away. Then the good eggs should be collected on a cloth, horsehair sieve, or fine canvas, hung up to drain from the water, and afterwards spread out on cloth or blotting paper to dry, being now and then turned with a spoon, separating them gently with the hands as the drying proceeds. Some authors recommend soaking the eggs in wine, brandy, or certain chemicals as preservatives from disease. I consider the proceeding very unnatural; but using water is but following Nature's course, for the eggs on the mulberry trees in the silkworms' native country are exposed to rain.

The reasons for detaching the eggs from the linen are to separate the good from the bad—to clean, weigh, and arrange in the hatching box in less space, and thus to facilitate collecting the worms. The Japanese breeds sent over to France and Italy are on cardboard, and are left to hatch on it, because to scrape them off when wetted is almost impossible without bits of paper coming away with them. Eggs produced at home would be preferable, but at the present day it is considered necessary to procure them every year or two from the native country of these breeds, or at least from certain districts free from disease.

Eggs of good quality are of a grey ash colour rather inclining to violet, spherical, somewhat depressed in their centre, and elastic under the pressure of a person's nails. A transparent fluid issues out on their being broken, and if thrown on the fire they will crack.

It would add to success in rearing silkworms in England if the hatching of the eggs were retarded by keeping them as cool as possible after January, without freezing, in earthen pots, pans, or jars in a dry cellar. If the mulberry trees are well in leaf as early as the middle of May, the eggs may be set to hatch, and this is early enough; indeed the end of the month is better, but sometimes it would be impossible to prevent natural hatching before this time, unless by means of an ice house.

If eggs have not been preserved properly, they will often hatch by the end of April before there are leaves for them, and oblige the rearer either to throw them away, or try a portion only on lettuce until the mulberry leaves are more forward.

When the eggs are about to hatch they assume a whitish cast. A few worms may very probably be seen out. When this is the case, no alternative remains but to bring the eggs from the cellar to an upper room, and deposit them in the hatching box. Whatever the natural temperature may be in the room towards the time the sun goes down, that is to be maintained all night in the little hatching room, to which the eggs are removed. Suppose such temperature to be only 55°, next day let it be raised gradually, until at night it is 65°, and by the following morning 70° may be reached and maintained continually. Should the temperature on the first day be more

—60° for example, then it should be raised more slowly in proportion. By the time 70° is reached doubtless the worms will be fully coming out of the eggs; and it will be as well to temper the dryness by sprinkling a little water in the room, which will have a good effect on the worms, facilitating their exit from the shells. Some persons hang wetted towels below the eggs, which answers the same purpose.

Presuming the eggs to have been preserved well, and therefore not so near hatching, it is desirable to extend the raising of the temperature over the space of five or six days before arriving at 70°. Bring the eggs from the cellar into a place but little warmer the first day; give more heat the next, raising the temperature in proportion to what it naturally is only rom 2° to 5° daily.

The eggs may probably not hatch before eight or ten days, but the worms will then be finer and stronger. They generally come out of the eggs in the morning soon after sunrise. Observe when hatching to keep a screen before the fireplace or stove, to prevent the artificial heat playing directly on the eggs, which would injure them. A thermometer should always be near them, and it is as well to have another outside the window of the room, that it may be known when the temperature there is such that more air may be admitted. The earlier or later hatching of the eggs is always in relation to the more or less elevated temperature at which they have been preserved from the end of January. Hardly any degree of artificial heat would hatch them before this month. The formation of the worms in the eggs may be known by the change from the ash colour to a darkish white, after which they soon come forth.

Probably the first day only a very few hatch and are not worth collecting, as also may be the case on the last day; therefore it is a good plan to set hatching an eighth more in weight of eggs to provide for loss of this kind, as also for bad ones, besides the death of some worms during the rearing.

I intend showing the management requisite with worms from one ounce of eggs, which quantity will suffice to fill two of my castles as described, supposing all to arrive at perfection, which is not likely; but an eighth more in weight of eggs provides for all contingencies, and even presuming every egg to come to maturity there would still be room. For this small quantity of eggs, stove, fireplace, or lamp heat would be used, with my gutter paper instead of a box. The morning when the worms are seen hatching, lay over the gutters the tender leaves; the worms soon crawl on them, and when the leaves are tolerably well covered with worms, but not crowded with them, gently lift them on to a sheet of paper, and place them on the third stage of a castle, which is a convenient height, allowing of a standing position while attending to them. The removal of the worms to this sheet of paper may generally be executed in two operations—viz., one at 10 A.M., and the other at 1 P.M., after which no more eggs are likely to hatch until the following morning. Each day's lot is to be kept on separate sheets of paper, and four sheets will probably hold all, presuming they are hatched in four days.—LEONARD HARMAN, JUN.

OUR LETTER BOX.

FEEDING POULTRY (G. R. S.).—You can only arrive at a proper estimate of the food necessary for ten fowls by feeding them yourself, and taking the average of seven or eight days. The only point of difficulty you will have will be to make allowance for the condition in which they are when the experiment is begun. Fowls that are badly kept eat more at first, but as soon as they are in condition, they eat regularly. Rice is not good food. Where you have conveniences, it is best to buy your food wholesale, and having due regard to weight, the cheapest is the best.

FOWLS CHILLED (J. P. S.).—Your fowls are suffering from a chill. Discontinue the Indian corn and rice, give ship bread well moistened with ale, put camphor in their water, and supply them daily with large sods of growing grass, with plenty of fresh earth on these. Tell us next week of what material the floor of your house is composed.

MARKINGS OF HOUDAN CHICKENS (Ring Dutterell).—The Houdan chickens are black or nearly so when hatched. In selecting, we should choose those lightly spangled, as they all become more spotted as they grow older. In all breeds it is well to defer weeding as long as may be conveniently and profitably done.

REARING WOODCOCKS AND SNIPES (Idem).—We have reared both Woodcocks and Snipes, and have kept winged birds of the former. In every instance we found it necessary to cram the birds for some days. This was the great difficulty with young ones, as their long bills are so tender, and are easily injured. We fed them entirely on worms, introducing these at the corner of the mouth, and pushing them down the throat with a feather. After a couple of days, although they will not pick up the worm, they will swallow it of their own accord as soon as it is put in the mouth. At last if live worms be put in a very shallow vessel, and covered with mud one-eighth of an inch, they will pick them out and eat

them. The Woodcock is easier than the Snipe to manage. We have Ruffs, and Reeves and Godwits now, and have had them out of doors throughout the winter. We imagine a Ruff could only be shown at a Crystal Palace bird show.

CAROLINA DUCKS (Carolina).—Carolina Ducks are birds of feather, not of size. There is but one point—i.e., beauty and condition of plumage.

BANTAMS PECKING EACH OTHER (E. W. H.).—The propensity you name is an unnatural one. Failing any other solution, we always imagine such arises from a vitiated state of body. The first advice we can give is to separate the Bantams from the Dorkings, next to give less stimulating food than they have hitherto had, and lastly to let them have a good grass run. In the young grass there is plenty of natural poultry medicine, and they will find it. In a recent number we gave ample instructions for marking chickens.

PROMOTING GROWTH IN CHICKENS (Erob).—Hamburghs feather much earlier than Cochins. While the latter are covered with down, the former show spangling or lacing. Discontinue the rice, it is no better for chickens than sawdust would be for children. Barley is only good as occasional food. Give oatmeal or ground oats slaked with milk, and bread and milk. Continue the cooked meat, and give occasionally some bread and ale. May chickens are fit for winter shows.

PROTRACTED HATCHING TIME (W. Prideaux).—Two things suggest themselves to us. It may be that the hen which did not hatch until the twenty-fourth day did not sit closely the first few days, or at any rate the first day, not closely enough to cause any change to take place; or it may be the eggs were kept too dry, and it was only after long effort the chickens could free themselves from the egg. It is common out of a sitting of thirteen to have eight out at night, and the others not till the following morning. It is never safe to condemn a sitting because the twenty-one days have elapsed. Very lately we were asked to look at some eggs that had been bought, put under a good hen, and were all added. The purchaser was angry. We thought the egg neither felt nor sounded like an added one, and we dropped it on the ground, it contained a chicken that would have been hatched in a few hours. Nearly all the eggs were the same. It is always unsafe to condemn eggs till after two days' grace. We have heard of prolific peas, wheat, and barley. We advise Mr. S. to advertise his prolific poultry. We never before heard of three eggs per day.

DEFORMED CHICKENS (G. P.).—We cannot account for the deformity of the Houdans. From the number (seven) that are hatched all with wry necks, we should be disposed to alter the breeding stock.

SPANISH HEN'S DISEASE (Cobbett).—The Spanish hen was opened and carefully examined. Her liver was extensively diseased and enlarged, when divided large quantities of blood escaped from it. There was great inflammation on the bowels, which appeared to have come on suddenly, as the bird must have been in health shortly before death. As these appearances are often suspicious, we examined the contents of the crop, it contained small seeds like tares, quite white inside when divided. Could they be poisonous?

PRESERVING EGGS (Thomas).—You can preserve your eggs in lime. Fill a large pan with eggs till the bottom of it is covered, then have lime slaked with water till it forms a sort of smooth concrete, pour in till the eggs are covered; after the lime is firm put in another layer of eggs, cover a third with lime, and so on till the vessel is full.

ESTABLISHING A POULTRY SHOW (Medicus Rusticus).—You had better write to two or three of the secretaries of the poultry shows of which a list appears in this Journal. Ask for a prize list and rules, and enclose two postage stamps. You will find them nearly similar.

CENTRIFUGAL HONEY-EXTRACTING MACHINE (C. A. J.).—"I hope soon to redeem my promise. Absence from home and other matters which would not brook delay, have hitherto combined to hinder its fulfilment.—A DEVONSHIRE BEE-KEEPER."

EARLY DROPPES (J. L. S., East Cornwall).—The appearance of a couple of droppes (April 25th), in a strong stock at this season, does not denote a drone-breeding queen. They may merely be accidental, as stated in page 251 in reply to "T. W.," and in this case the Liguirians may yet be first in drone-production proper; or the black bees may take the lead in drone-breeding without being the stronger colony, either by reason of the queen being an old one, and therefore prone to lay drone eggs, or merely from the accidental presence of drone cells in the "brood nest."

PARROT SELF-PLUCKED (E. W.).—The plucking is induced by irritation of the skin. Do not feed on animal matters or heaped fruits and soppy bread should be the bird's diet, and let it have a tepid bath daily. Put a soap plate filled with the tepid water for the bird to make use of. If it does not bathe voluntarily, pour the water over it through the rose of a garden watering pot.

GOLD FISH (S. Shepherd).—It is quite impossible for us to tell what is the cause of your gold fish dying, not knowing the symptoms. It is possible that zinc tank may have a prejudicial influence.

CATTLE INSURANCE (H. F. F.).—There is no company in London now in which you could insure the life of your cows.

POULTRY MARKET.—MAY 6th.

WE have still a wretched supply of poultry, and if the trade were not worse than the supply, prices would be higher than they have been for many years.

From observations taken near London during the last forty-one years, the average day temperature of the week is 65.6°; and its night temperature 41.9°. The greatest heat was 89°, on the 22nd, 1847; and the lowest cold 25°, on the 15th, 1850. The greatest fall of rain was 0.58 inch.

INSECTS.

SOME persons attribute insect-attacks to defects in cultivation, and are clamorous in their inquiries as to the cause of plants being so infested with insects. That there is a cause for every effect cannot be disputed; but that there is any other reason for insects infesting a plant beyond that of their having in the plant attacked some substance which is necessary for their existence is very questionable. I willingly admit that

certain conditions are favourable to the spread of insect life, and that plants subjected to those conditions favourable to the development of insect life will be the most liable to attack. I must, however, differ entirely from those holding insect attacks to be indisputable evidence of the plant being in some stage of disease. Disease in a plant is in every sense distinct from a plant being infested by insects, and a plant will perish of the disease by which it is assailed without the occurrence of insects. I know that a vigorous and flourishing plant attacked by insects, if measures be not promptly taken to check their ravages, will be weakened, and lose the beauty of its foliage and flowers, and in the case of fruits these will be deteriorated both in quality and size. I am equally aware of the fact that a plant weakened by an attack of insects recovers its wonted freshness and vigour when freed of the parasites that suck out its juices. So far, then, am I from being persuaded that insects attack a plant because it is unhealthy or diseased that I give them credit for greater instinct, believing them to attack a healthy and vigorous plant oftener than one which is diseased and not so well calculated to meet their wants.

It is not my intention in this and subsequent papers to treat of the diseases, but of those insects infesting plants, which, if they do not kill, yet greatly impair their beauty of foliage, bloom, or fruit.

APHIDES.—Of these there are many species. Almost every plant subject to the attacks of aphides has its peculiar kind or species, and they are of insects the most common and speedy of increase.

Green Aphis or Green Fly.—The plainest characteristic of this pest is its colour. It is not very particular as to what it assails. The Pelargonium, especially the Show varieties, the Cineraria, and the Calceolaria, are its great favourites in-doors, whilst the Rose, both in and out of doors, is sure to be visited by it. The Peach, too, suffers much from aphides, but the species is not the same as those which attack the Cineraria, the under sides of Rose leaves, and the growing points of the Pelargonium. The Plum, too, has a green fly peculiar to it; and the Gooseberry, Currant, Beech, Lime, and Sycamore have their own species of aphides, all of which are great producers of honeydew—those infesting the Red and Black Currant, the Lime, Beech, and Sycamore being the most prolific. Honeydew, I may state, is not caused by the influence of the air, and where there are no aphides above there is no deposit of the sweet secretion known as honeydew, of which the humble or bumble bees and wasps take their fill, and

make a noise in large plantations on a fine day not unlike that of a swarm of bees high in the air. The honey bee does not, so far as I have observed, gather honeydew; but the wasp will not only suck the honey, but devour the producer of the honey.

All the species of green aphids are destroyed by tobacco smoke, by a decoction of tobacco in water, and by powdered tobacco.

For plants under glass the simplest and at the same time the most effectual method of destroying the green aphid is fumigation with tobacco. It not only destroys the insect, but acts for a time at least as a preventive. The fumigation should take place on a calm evening, and if the outer air be light and damp all the better. The house should be shut up closely, and where practicable a covering of canvas or mats to confine the smoke would render the fumigation more effectual. The foliage of the plants should be dry, but to prevent any injury to them from the dryness of the atmosphere the floors and every surface, so far as it can be done without wetting the leaves, may be syringed. Nothing is equal to the leaf tobacco for fumigation, Cavendish being the best that I have used. Thin paper saturated with the juice of tobacco undiluted with water is also useful, and that in which pigtail is wrapped prior to pressing, and when it comes off, is excellent, and when thoroughly saturated quite equal to tobacco leaf. English-grown Tobacco is also good, but not equal to the preceding. The thick paper steeped in tobacco juice much diluted with water is too uncertain in its effects on the green fly, and it will not burn well, nor will it keep without turning mouldy. It is a sure sign of bad quality in tobacco paper or tobacco when either turns mouldy. Then little or none of the active principle of the tobacco is left, and the material burns rapidly, instead of smouldering without much blowing as in the case of thin paper steeped in undiluted tobacco juice. The paper should be torn into pieces about the size of a crownpiece, and if tobacco leaf be used it should be thoroughly chopped or cut.

The best mode of making an apparatus for fumigation is to form a piece of sheet iron into the shape of a flower pot, and to add to it a copper bottom pierced with quarter-of-an-inch holes. This should be put in about 1 inch from the base, and be secured with rivets, as should the joints of the sheet iron. The apparatus may be 9 inches in depth, 7 inches in width at top, and 5 inches at bottom. Under the grating, or bottom, holes should be cut in the sides to admit the air beneath the bottom or grating, and in one side immediately above the bottom should be a hole with a tube of sheet iron, about 3 inches long, rivetted to the side, the tube and hole being large enough to admit the nozzle of a pair of bellows.

Previous to being used the apparatus should be set on the floor, and as near the front of the house as possible; if there is no floor in front, then set it on a tile or slate. Place a few pieces of red-hot charcoal on the grating, and then a small quantity of the tobacco paper or leaf; apply the bellows, and when well lighted, add more paper or leaf, continuing to add more and to blow gently until the

whole is well alight, and the house so full of smoke as to be unpleasant. Next add more paper, and quit the house when enough has been put on to fill it so full of smoke that a plant cannot be seen from the outside. The paper or leaf should be damp or limp, but not so wet as to require constant blowing, for if wet the operator must remain in the house most of the time. It is enough if the green fly be killed, and that it will be if the paper or leaf be good, and the house filled with smoke.

There are several fumigators. I have tried many, but I do not care for any beyond that described, which any smith can make; indeed, were not flower pots so liable to crack, I would as readily use one with a hole in the side as the best of the fumigators. If flower pots are used hard ones should be chosen, and put pieces of lath or slate beneath them, so as to let air in by the hole in the bottom.

The day after fumigation the house should be kept as close as practicable, not giving more air than can be avoided, and a moist atmosphere should be maintained by sprinkling the floor and other surfaces with water, but do not syringe until the evening; then give a thorough syringing, and again on the following morning, and admit air.

Various methods have been proposed for fumigating houses without having to stand the annoyance of the smoke. They have with me signally failed. I have, however, the pleasure to state that I had a canister of "Tobacco grains," a preparation made of duty-free tobacco, which I think is likely to supersede the troublesome and annoying mode of fumigation hitherto practised. The "grains" have the appearance of mahogany sawdust; all that is required is to spread them rather thinly on a plate or tray of sheet iron pierced with a number of small holes. The house is then shut up, as for fumigation with tobacco or tobacco paper, and the tray being placed in front of the house the "grains" should be lighted in several places, a piece of paper being sufficient. They burn like a fuse, produce smoke, and the house being filled with this the green fly is destroyed without injury to the foliage, although I expected before trying the materials that the contrary would be the case. After lighting the "grains" the operator may quit the house, and before he has so much as sneezed. I understand the price is to be one-fourth that of tobacco. It cannot fail to be a boon to amateurs and gardeners.

Fumigation with tobacco is the best of all remedies for the attacks of green fly. It may be employed for plants in as well as out of flower, and it does not dirty their foliage, nor injure it when used in solution, and powders are apt to do so. It is a cure as well as a preventive, and should be resorted to whenever a plant is in the least infested. The best natural preventives of green fly are giving an abundance of air, keeping the house cool, the plants as near the glass as possible, and giving frequent and thorough syringings.

As fumigation cannot well be practised on plants and trees in the open air I must defer reference to them until another time, and conclude this first communication with a statement of my firm conviction that no other mode of freeing plants under glass of green aphid is equal to tobacco smoke. There are other modes, but I cannot do more than state what I have proved to be the best, and that I shall strictly adhere to in subsequent notes.—G. ABBEY.

(To be continued.)

THE LOQUAT.

It is to be regretted that Mr. Bateman in his lecture on May 5th, as reported in your columns, did not go more fully into the culture of this fruit. The best description of it is to be found in Loudon's "Encyclopædia of Gardening," where also may be read an account of how the trees were managed at Lord Bago's. It was, I think, hoped and expected that Mr. Bateman would have thrown some new light on its culture. There is no doubt about the excellence of the fruit when grown in a climate suited to it. A friend who lived in St. Helena some years reports it as being peculiarly excellent there. As grown in the south of France it is said to be good, but I have only eaten it when preserved in syrup, in which state it has not the least flavour, but is merely a lump of sugar with two or three stones enclosed.

Some years ago I was much interested in this tree, which is one of the noblest of evergreens, and I found that the trees raised from seed, which may be done with great facility, would take a lifetime before they would bear fruit in this country, and under the artificial treatment here practised. The best

mode I soon found was to graft scions, from old trees if possible, on strong stocks of the Whitethorn (*Cratægus oxyacantha*), growing in the open air, and then to put them into large pots by the end of October. The stock should be stout, and if as stout as a small broomstick all the better. The grafting and the confinement of the roots to the pot soon make the tree ready to bear fruit.

The best method of grafting is that called rind-grafting, which is done by paring the graft very thin, and then inserting it between the bark and the wood; this is best done in April, towards the end, when the bark rises freely. As the leaves of the Loquat are large, they should be removed, with the exception of those at the crown of the shoot. The grafts should then be firmly bound as usual and clayed, binding some moss over the clay; or a better practice would be moulding the stock and graft up to its tip with cocoa-nut fibre. If the weather be hot and sunny the grafts should be shaded for a week or so, by placing a flower pot over them, tilted up on its northern side. Loquats may be grafted even now if stout stocks could be found. Some of the ends of the shoots from the tall naked-branched tree now in the conservatory at South Kensington would make excellent grafts. By the end of October the grafted trees may be taken up and potted, or planted out in a house prepared for them. If they have made vigorous growth they will soon make bearing trees if properly treated, and the treatment required seems at present not very clear.

The account given in Loudon's "Encyclopædia" of Lord Bago's mode of treatment is very interesting, but in my opinion the Loquat should not be considered a stove plant; for, as it grows and bears freely on the shores of the Mediterranean with a mild winter and hot summer, I see no reason why it should not ripen its fruit here in a climate under glass approximating to that of the above localities. It therefore seems to me that grafted trees should either be grown in 18-inch pots with a rich compost, or planted in the borders of a well-ventilated orchard house, fitted with hot-water pipes to give the temperature in winter necessary to their well-doing.

The routine culture should be as follows:—From the 1st of June till the last week in October the house should be open night and day, the trees being watered and syringed as required. From the 1st of November and all through the winter the minimum temperature should be 50°, thus imitating the climate of, say, Hyères in the blossoming season. During March, April, and May the same gentle artificial heat should be continued. This, with the occasional high temperature which sunshine will give, will ripen the fruit, and free ventilation without artificial heat during the summer and autumn months, during which the temperature of an orchard house ranges from 70° to 95°, till the 1st of November, will give health and strength to the trees, so that they will blossom in December, and set their fruit freely.

The Loquat is such a magnificent evergreen, independent of its pleasant fruit, that it is almost worthy of a house being devoted to its culture; but this need not be, for if some of our best kinds of dessert Oranges are planted with it they will succeed, and ripen their fruit in great perfection. As a preserve in syrup the Loquat is merely a vehicle for sugar, and has no peculiar flavour; if bottled and preserved without sugar it would retain its agreeable acidity, and be an excellent fruit for tarts.

In selecting trees for cultivation, care should be taken not to plant trees raised from seed, but those grafted either on the Pear or Whitethorn. If possible a good free-bearing variety should be selected, as they, like all our cultivated fruits, are apt to differ, as far as I recollect and have heard, not only in the size of their fruit, but in their bearing qualities.—MESFILUS.

ANTHURIUM SCHERZERIANUM.

THIS plant may be reckoned among the finest of modern accessions to our stoves. It is a distinct and beautiful dwarf-growing species, which even in a small state produces in great abundance its large scarlet flower spathes, which last in good condition for three months. It appears to be a plant very easy to cultivate, growing and flowering freely in a shady part of an ordinary Pine stove. Indeed so useful and effective a plant does it appear to be, that it is worthy of being grown by the dozen where there is much demand for decorative stove plants.

It grows freely in a mixture of sphagnum, peat, sand, and broken potsberds; and although it makes nice flowering plants in 6-inch pots, it seems to like rather a liberal amount of pot

room, and an abundant supply of water. Treated thus, it continues to make fresh leaves and flowers for a long time without any rest. It is a plant which can scarcely be too strongly recommended.—D. THOMSON (in *Gardener*).

BEDDING PLANTS

THAT MAY BE PLANTED OUT EARLY, AND OTHERS TO BE PLANTED LATE.

(Concluded from page 337.)

HAVING described the class of plants that may with advantage be planted out early in the bedding season, let us now turn to those which experience has proved ought not to be trusted out of doors too early, as nothing is gained by doing so; but, on the contrary, the cold air and chilly winds so check or damage them that they are generally later in arriving at perfection than those planted out later. In general, but not always, the hardness of the plant or otherwise determines this, for some plants not unusually met with under plant-stove treatment, suffer no more than others from temperate regions. A *Perilla* or *Tropæolum* is quite as susceptible to cold as a *Coleus*, when that cold sinks to 32°, although the latter makes less progress than they do while the night temperature is about 40°, and there are, besides, some other qualifying circumstances. The class of plants which it is advisable not to plant out before the third week in May, is a large one, and embraces many of the most prominent ornaments of the parterre. A few only will be noticed here.

SALVIA, especially *Salvia splendens*, are very tender, and ought not to be planted out too early, but *S. fulgens* may be planted out sooner than the others.

COLEUSES ought not to be planted out till the 1st of June in most places, and will succeed if they have been kept in a growing condition up to that time. They may be regarded as among the very latest that should be planted out.

PELARGONIUMS, if in separate pots, or tied up in moss so as to remove easily and well at any time, ought not to be turned out until the middle or towards the 20th of May, or even later if the season be an adverse one; but when they have been some time crowded in cutting pots or boxes, and are evidently injuring each other, they may be planted out earlier, provided shelter can be given to them in the beds—say a few laurel houghs or some such shelter from high winds and cold nights. It must be remembered that it is not advisable to plant out anything until the ground is in a fit state, nor is it recommended to plant out bedding *Pelargoniums* direct from the cutting box or pan if any means can be adopted for giving each of them a separate pot or ball of earth; but this cannot always be done, and when it is not, the flowering of course will be somewhat later. Where there is accommodation only for a few plants potted off singly, the general plan is to favour the most choice varieties, such as the Golden and Tricolor kinds, but this every one will judge for himself.

AGERATUMS.—These plants are very susceptible of frost, and they seem to like dry hot weather; but they are amongst the first in autumn to show the effects of frost, and ought not to be turned out too soon.

PERILLA NANKINENSIS.—Although capable of growing well in a dull cold season, yet a little frost destroys the young plants, as was proved here in the frosts of May last year; for though Scarlet and other *Pelargoniums* in the same position were not much injured, the *Perilla* was completely killed. If the plant can be protected from frost the cold air will do it no harm, as I have had it in a cold pit, only covered up with some boarded shutters at night, all through April without its sustaining any injury. Frost, however, is fatal to it.

AMARANTHUS MELANCHOLICUS RUBER.—This will not endure any great amount of cold or damp, and is much more tender than *Perilla*. A bright sunny period suits it best, and when the plants occupy a position between the spectator and the sun they appear to the greatest advantage.

IRENE HERBERTII.—The only recommendation this plant has, as a friend sarcastically said of it a few days ago is, "that it is tender." The only times at which it really looks well are in the spring months when it is in course of propagation, and late in the autumn if it has had the fortune to do tolerably well. As a summer plant it is only second-rate, if even so good as that. It will not do well planted early.

DAHLIAS.—These are more tender than bedding *Pelargoniums*, and although they do not suffer when planted early if they are good well-established plants, and some protection is afforded

them in case frost should occur, yet they seldom make any progress until warm weather sets in.

Of plants with remarkable foliage, the Castor-oil plants and *Solanums* ought not to be turned out till the end of May, and the same may be said of Tobacco, choosing dry weather for transplanting the latter plant, as slugs are very fond of it. *Wigandia* and *Ferdinanda* are also better kept in-doors until fine weather sets in, and the same may be said of most similar plants whose growth is rapid when it does start. It would not be prudent to let the plants get damaged and chilled by cold previous to the proper growing period, and the first crop of hay may be cut ere many of the stove plants which it has been the fashion of late years to plant out be turned out of doors, for established summer weather alone is suitable for them, and the best results of such displays are invariably obtained in those cases in which there has not been too great hurry in planting out. The same remark also holds good in many respects as to ordinary bedding plants, excepting, of course, those mentioned last week.—J. ROBSON.

HORTICULTURAL EXHIBITIONS TO BE HELD DURING THE PRESENT YEAR.

THE following provincial Floral and Horticultural Societies have announced their intention to hold exhibitions and meetings on the dates specified below during the months of May, June, July, August, and September. Those marked with an asterisk (*) are in union with the Royal Horticultural Society.

	May.	June.	July.	Aug.	Sept.

In addition to the above, exhibitions and meetings will be held October 14th and November 18th by the Royal Jersey Agri-

cultural and Horticultural Society; on November 18th by the Cambridge Horticultural Society, and on November 26th by the Royal Horticultural Society of Ireland.

ROSES AND SPRING FLOWERS.

MR. WILLIAM PAUL'S NURSERIES, WALTHAM CROSS.

A VISIT to these nurseries at any season is sure to be found interesting, especially so in the spring months, when the noble array of early-flowering plants which Mr. Paul has for some years past successfully cultivated and exhibited is in its beauty. Spring gardening as it is called, or, more correctly, floriculture for spring, is beginning to receive the share of public attention it naturally claims; for it is in the early months that the hopes of the florist are most strongly excited, and the first flowers of the year always receive the heartiest welcome, if not the greatest share of admiration. True to the high character which Mr. W. Paul has maintained for so many years as a leader in horticulture, he is constantly drawing upon resources hitherto neglected or left in abeyance, developing new beauties for the decoration of the pleasure and flower garden, pressing into service subjects generally left to the nooks and corners of the humble cottage plot, and even found wild in the hedges and fields.

We should call nothing common, in a depreciatory sense, that is beautiful, even if abundant. There is beauty in the wayside plant trodden under foot. There is marvellous beauty in all those pretty flowers blooming in the hedges and fields in the early spring, could we but appreciate them aright. Our leading horticulturists, then, are wisely moving in a proper direction in showing us how these things may add still further to our gratification and enjoyment by introducing them with judgment into the flower garden, and blending their delicate hues with other flowers of more gorgeous colours.

The common Bluebell, *Hyacinthus non-scriptus*; Forget-me-not, *Myosotis*; Daisy, double crimson and white; varieties of *Primulas*, usually known as *Polyanthuses*; *Aubrietias*, *Pansies*, *Wallflowers*, and many other familiar favourites are all employed at Waltham with charming effect. If to these are added the now-well-known *Alyssum saxatile*, variegated *Arabis*, and scarlet *Anemone*, it will be seen that a variety of and even brilliant display of colours are brought together, offering an almost unlimited field for the exercise of tasteful arrangement and combination. Few travellers on the Great-Eastern Railway can have passed the Waltham station within the last fortnight, without having their attention arrested by the beautiful circular beds near the railway, planted with the brilliant *Rex Rubrorum* Tulip, edged with *Bluebell* and *Alyssum saxatile*, and backed by other beds of plants above named.

I should not have made more than a few passing notes on these early hardy flowers, had not their intrinsic merits absolutely required more. To single out from amongst them one subject deserving especial notice, the *Polyanthus* tribe, or those varieties of it cultivated at Waltham, are the most conspicuous. The kinds selected are all distinguished for the mass of blooms produced by each plant; the colours are pleasing and distinct, equally suitable for massing or for single specimens. The same admirable discrimination is also shown in the selection of *Pansies*. All of these spring-flowering plants being perfectly hardy and easy of culture, I was glad to find that they are being propagated extensively, so that in another season no one need be without them.

Nor is it with herbaceous and bulbous plants only that the spring garden can be made completely attractive. With few exceptions, by far the greater number of ornamental trees and shrubs esteemed for their flowers produce them in the early months of the year; and in my opinion they should not be regarded simply as an adjunct, but a principal feature in the decoration of the spring garden; and although notices of single species and lists of selected kinds frequently appear in these pages, the subject admits of further elucidation—much more so the now numerous varieties of deciduous shrubs and trees with variegated or coloured foliage that show their "quiet beauty" later in the season. Easy of culture, growing in almost any soil, the planting and arrangement of deciduous trees and shrubs have nevertheless of late failed to receive the share of attention they merit. The contrast and relief such afford, in the summer and autumn months, to the masses of gorgeous colour now sought for in these seasons, have yet to be more fully developed. A more enlarged, and I think I may add a more enlightened, taste in ornamental gardening, is be-

ginning to be manifested. We shall yet see them in their proper place and rightly appreciated. The choice and at the same time extensive selection Mr. William Paul has at Waltham will do much to bring them under general notice; and I trust that in time able pens will direct attention to them, to which I will venture to hope to join my mite in a future paper.

But the Roses, the chief and most attractive of all the flowers at Waltham, I must beg pardon of the readers for my digression, especially of the very numerous ones who peruse "our Journal" almost solely for Rose intelligence. I am conscious of their impatience. Week after week have they had to look through the pages, and have found of late little or nothing respecting their favourites; and if we grant that the subject is well nigh inexhaustible, they should bear in mind that our Editors have to take cognisance of the whole range of subjects connected with horticulture, and each must have its turn. At length they will allow a little gossip about our flower; and the season for out-of-door bloom and the shows being at hand, we may anticipate our full share.

The Roses at Waltham are, as they always are, in fine condition. It is not my purpose here to raise any question *pro* or *contra* respecting forced Roses, but to record what I saw, and that which any reader may see and judge for himself on any day. Forced Roses are a great luxury; to prolong the season of our glorious flower in either direction is a great treat; and when accomplished, as Mr. W. Paul has for years past done, and shown how to do, there is not much room for argument in the matter. Roses if over-forced, or too early, or unskillfully managed, are eyesores to the rosarian; they are miserably deficient in form and colour, and too often their growth is "leggy." Not so with the splendid specimens exhibited by Mr. Paul, and other eminent growers, nor, indeed, with a single plant of the multitude now growing in the various glass structures at Waltham. With respect to colour, I may note an instance. If any Roses suffer in this point they are the dark kinds. Now, on the day of my visit (April 25th), a plant of *Empereur de Maroc*, one of the darkest Roses known, showed several blooms of its velvety maroon flowers without a single hitch or fault. Many specimens of other well-known kinds were similarly perfect. Hence, in offering the following notes of new kinds for the information of our Rose friends, I do so with something like confidence that when proved in the open air they will be found as now described.

ROSES OF 1867.

Charles Verdier.—Pale rose in colour. Very globular and full, not unlike the old Cabbage Rose, but better formed, and with more substance in the petals. Remarkably good.

Souvenir de Monsieur Boll.—One of the largest of Roses, carmine red, showing some resemblance to *Madame Boll* in habit and foliage. Very vigorous.

Antoine Ducher fully maintains the character given of it last autumn, bright red in colour, beautifully cupped, very remontant. A noble flower.

Comtesse de Jaucourt.—Somewhat like *Caroline de Sansal* in form and colour, but more regular and deeper, a kind of rosy flesh, decidedly beautiful, freely remontant. This variety promises to be a very useful garden Rose on account of its distinct and delicate colour, combined with free blooming. Of a large number of plants in Mr. W. Paul's houses nearly every one had one or more expanded flowers, with others immediately to follow.

Eugène Scribe.—Like *Jules Margottin*, with nothing particular to distinguish it from, or to induce a preference to that fine old Rose.

Madame Pulliat promises to be one of the best of its year; deep rose, full, globular, and vigorous; not quite so large as some of the preceding.

François Treyer is another addition to the host of scarlet crimson, or crimson scarlets; of excellent shape.

Madame Anna Bugnet will prove a favourite; colour delicate satin flesh approaching white; of beautiful shape.

Adrienne Marx.—Bright carmine red, large, not superior to others of similar colour.

Baronne Hausmann.—Bright cerise red, large, but not full; requires further trial.

Monsieur Furtado.—Tea-scented. This promises to become one of the most admired of Tea Roses; very large and full, perfect form, sulphur yellow, deeper than *Solfaterre*, and of much better shape; superb.

Madame Margottin.—Another Tea Rose of the same season

sustains the reputation it gained last year. A truly first-class flower.

ROSES OF 1868.

Boule de Neige.—A pure white Rose, of excellent shape, resembling *Madame Hardy*, very vigorous, and if sufficiently rampant will prove an acquisition, being the best white yet obtained in this class.

Madame Noman.—Another white, which at first sight I took to be *Madame Plantier*. The resemblance to that well-known variety both in flower and foliage, is very close indeed.

La France.—Lilac rose with deeper centre; colour not easy to describe; petals excessively recurved; like *William Rollison* in shape, but totally different in colour. It may please some people.

President Willermoz is a reproduction of *Lord Palmerston*, superior to the older variety on account of vigorous growth; bright cherry red in colour. By those who remember and admire the Rose named after the late veteran Premier, *President Willermoz* will be cordially accepted.

Madame la Baronne de Rothschild.—Thus far undoubtedly the Rose of the present season, strikingly beautiful in colour and form; a pale satir rose, of perfect form and substance, exquisitely shaped, growing well. This lovely Rose not only promises to be the best of the season, but to obtain a reputation that will endure for years.

Souvenir de Francois Ponsard.—Another Rose with a very long name, and close resemblance to our old friend *Jules Margottin*, perhaps a little lighter in colour. Very fragrant.

Merveille d'Anjou, described in the French lists of last autumn as being of a purplish red. A desirable colour, but the red so predominates that the purple element is difficult to discover. Altogether not very promising, further trial may show it to better advantage.

Clotilde Rolland proves true to description—that is, beautiful pale rose, with the form of *Madame Furtado*. We have in this variety a vigorous growth with all the excellence of that fine Rose. *Madame Furtado* will now be given up.

Baron Hausmann.—In the notice of last year's novelties there is one named after *La Baronne Hausmann*. I may have made a mistake in my notes, for they are as much alike as two peas; but it matters little, for neither as yet shows any likelihood of gaining favour.

Duchesse d'Aoste.—Another rose-coloured variety, large and full, *Jules Margottin* over again nearly. The blooms I saw of it were good.

Prince Humbert.—A good dark Rose, likely to gain favour for a time, but not superior in my opinion to *Souvenir du Comte Cavour*, by the same raiser (*Margottin*, of *Bourg-la-Reine*), which it much resembles in colour. It is, however, fuller. It is evidently not equal to such flowers as *Senateur Vaise*, *Lord Macaulay*, and others of the same class.

Madame Marie Cerodde.—Very much like *Baron Gonella* in form and colour, sometimes described as "dove pink," very fragrant and beautiful. A good Rose.

In the house assigned to Tea Roses at Waltham, the bloom was abundant and fine. The following, most of them well-known and esteemed kinds, I have noted as the best:—*Boule d'Or*, Climbing Devonensis, like the old Devonensis, first-rate; *President*; *Madame Willermoz*, very fine but delicate in colour; *Souvenir d'un Ami*, still one of the very best in its class; *Jaune d'Or*, not much of yellow or gold about it; *Comte de Paris*; *Narcisse*, *Niphetos*, *Solfaterre*, *Madame Falcot*, *Celine Forestier*, *Madame Bravy*. But, see, there is one among them of a very different class, with gorgeous flowers of unrivalled brilliancy, making its way to the very top of the house, sending forth buds and grand flowers at every step in its progress, clothed with massive foliage of beautiful glossy green hue—a Rose that possesses every good quality yet discovered in any or every variety, blooming early in the season, continuous through it till the frosts of winter alone stop it, suitable for pillars, forming a fine head as a standard, flourishing in soils where many will not grow, on its own roots, on the *Manetti*, on the *Briar*—its name is *Charles Lefebvre*.—*ADOLPHUS H. KENT*.

PRESERVING PEAS FROM MICE.—Among the numerous plans recommended for preserving new-sown Peas, &c., from the ravages of mice and birds, I have never observed the following:—Cut up, tolerably fine, in a hay-cutting machine, a quantity of common Gorse, and sow it rather thickly on the top of the Peas, then cover up with soil. The Gorse does not seem in

the least to prevent the Peas coming up, and I have tried it a good many times, and have never known it fail.—*J. G.*

[The plan has been frequently recommended and practised very successfully.—*EDS.*]

ROYAL HORTICULTURAL SOCIETY.

THIRD SPRING SHOW.—*May 9th*.—This was not a success so far as the flower which was intended to have constituted the principal feature was concerned, for the magnificent specimens we have been accustomed to in former years were absent; so were the Roses, but of miscellaneous subjects there was, as at the previous show, an extensive and interesting display.

In Class I, nine Azaleas, for nurserymen only, there was no exhibition. In Class 2, for amateurs, Mr. Wilkie, Oak Lodge, Kensington, was first with well-bloomed plants, about a yard high, of *Criterion*; *Stella*, a brilliant-coloured variety sent out by Messrs. Veitch two or three years ago; *Concinna*, lilac purple; *Marie Vervaeke*, white, flaked with rose, a beautiful variety; *Eulalie Van Geert*; and *Rubens*. Mr. F. A. Steel, Hammersmith, was second, with, among others, a large plant of *Semiduplex maculata*.

In the nurserymen's class for six, by far the best collection of Azaleas in the Show was exhibited by Messrs. Lee, of Hammersmith, and deservedly received the first prize. They consisted of *Duke of Devonshire*, salmon scarlet; *Extraneus*, a fine mass of rosy crimson flowers; *Leeana*, white; *Petunioflora*, rosy lilac; *Marie Louise*, crimson; *Victoria*, white, spotted and flaked with purple. Messrs. Dobson & Sons, Isleworth, took the second prize with a compact bushy specimen of *Murrayanum*; *Bouquet de Flore*, not sufficiently forward; *Iveryana*, *Model of Perfection*, *Delicata*, and *Duc de Nassau*, semi-double, crimson.

The only exhibitor in the class for single specimens of Azalea was Mr. Wilkie, who had a first prize for a plant unnamed, but apparently the old white, forming a fine pyramid standing about 7 feet high, and covered with bloom.

Of *Rhododendrons* Mr. Wilkie exhibited half a dozen standards with large heads covered with fine trusses of white, pink and lilac, and crimson flowers, and took a first prize; likewise a similar award for a fine standard. Mr. Steel, Hammersmith, was second with a small but well-bloomed plant of the variety called *Purpureum grandiflorum*.

Of *Auriculas*, the only exhibitor was Mr. James, gardener to W. F. Watson, Esq., Isleworth, who sent, of Green-edged, Miss Farnell and *Lancashire Hero*; Grey-edged, Jane Smith and *Duke of Cambridge*; White-edged, *Smiling Beauty* and *Model*; Selfs, *Cheerfulness* (*Turner*), and *Royal Purple*. Miss Farnell, Jane Smith, and *Smiling Beauty* were excellent, and the rest were in good condition for this period of a season when the bloom in the south has been rather early, and Mr. James deserves credit for retarding his plants so successfully and producing such a good exhibition, the only one in its class. A first prize was awarded him for these, likewise for half a dozen *Alpine Auriculas*.

Of *Polyanthuses*, both Mr. James and Mr. Wiggins, gardener to W. Beck, Esq., Isleworth, sent well-grown and well-flowered plants. Among those from the former were *Goldfinch*, a showy free-flowering kind and well laced, *Juliet*, and *Picturata* also attractive; while Mr. Wiggins had *Maggie*, a rich-coloured flower, and *Gold Crown*, a dark ground, conspicuously laced with yellow. Mr. James took the first prize, Mr. Wiggins the second.

Of *Paucias* in pots, Mr. James, who was awarded a first prize, had a beautifully-flowered set of eight, consisting of *Rev. H. Dembrain*, *Dr. Ingler*, *Baronne de Rothschild*, *Cherab*, *Vesta*, *J. B. Downie*, *Dr. Smith*, and another. Messrs. Dobson took the second prize; and Mr. Sheuton, nurseryman, Biggleswade, and Mr. James, had extra prizes for stands of cut blooms.

Prizes were also offered for *Lily of the Valley*. Mr. Reeves, *Ladbroke Nursery*, was first with pots in excellent bloom; Mr. August, of *Beddington*, being second, and Mr. Wilkie third.

The best collection of twelve *Alpine* plants came from Mr. Salter, of *Versailles Nursery*, Hammersmith, and in it were *Smilacina bifolia*, with small heads of white flowers; *Saxifraga aizoon*, and *S. hypnoides* minor, a pretty, dwarf, moss-like plant, which forms a neat covering for borders; *Arenaria balearica*, with flowers like minute white stars; *Aubrieta deltoidea variegata*; *Sedum glaucum*, which forms a charming carpeting; *Sempervivum Pattonii*, and *S. arachnoideum*, very interesting from its appearing to be covered with cobwebs, a circumstance from which its name is derived. Mr. Ware, *Tottenham*, who was second, had various *Saxifrages*, conspicuous among which was *Saxifraga granulata plena* with large double white flowers, also *Sedum Forsterianum*, having a reddish tinge.

Of miscellaneous subjects there was, as already remarked, an extensive display. Mr. Williams, of *Holloway*, had an extra prize for a collection containing a finely-bloomed specimen of *Clerodendron Thomsonae Balfourii*; *Saccolabium retusum*, *Cypripediums*, and other *Orchids*; *Aphellexes*, *Heaths*, *Eriostemons*, *Amaryllids*, *Genetyllis Hookeri*, *Franciscea calycina*, and a good example of *Anthurium Scherzerianum*. Mr. Bull had a similar award for a collection in which there were several new *Coleuses*, the best apparently being *Gem*, chocolate with a green edge, and *Crimson Velvet*, reddish chocolate,

both richly coloured varieties. Among his other plants we noticed a fine specimen of *Cibotium regale*, a fine pair of variegated Aloe-leaved *Yuccas*, a beautiful mass of *Trichomanes radicans*, *Anemia lineata*, and *Dracena Banksii* in flower, Bronze and Gold Zonal *Pelargoniums*, *Azaleas*, and a pretty striped *Petunia*, called *Herald*.

Messrs. Veitch sent a remarkably fine group of plants not for competition, consisting of *Sauzechia nobilis variegata*, one of the best-marked of new variegated plants; *Maranta Veitchii*, now well known as one of the finest of the *Marantas*; *Alcascia Jenningsii*, with bright green leaves regularly marked with dark blotches betwixt the veins; *Abutilon Thompsoni*, with leaves blotched and mottled with gold; *Azalea Stella* and *Marie Vervaene*; *Primula cortusoides amena*, of which a striking variety was shown at the last Floral Committee; *Davallia parvula*, with pretty finely-divided fronds; a specimen of *Cypripedium candidum*, with five fine flowers with tails 2 feet and more in length; *Begonia boliviensis*; *Nepenthes Rafflesiana*, with ten large pitchers; *Anthurium Scherzerianum*, with ten of its brilliant scarlet spathes, and three more about to expand; and, lastly, the new *Colasias* which the firm has recently acquired, and which, it cannot be doubted, are destined to take a high place in ornamental gardening. Messrs. Lee sent, likewise not for competition, a collection of plants, in which were good examples of *Orchids*, *Heaths*, *Azaleas*, *Eriostemons*, *Yucca quadricolor*, and *Cordylina indivisa*; and Messrs. F. & A. Smith, Mr. Wilkie, and Mr. Reeves had extra prizes for miscellaneous collections; Mr. Bartlett for a number of pots of *Spiraea barbata* or *Hoteia japonica*; Mr. James for fine herbaceous *Calceolarias*, also for *Cinerarias*. An extra prize was also awarded to Mr. Salter for a large collection of hardy variegated plants. Among them were *Beta chilensis*, with violet crimson shaded stalks; several *Funkias*, *Spiraea linnaria*, with the centre of the leaflets striped and blotched with golden yellow; variegated *Lily of the Valley*, very pretty; *Hemerocallis Kwanso plena variegata* with long white-striped leaves; *Sedum Sieboldi variegatum*; *S. Faberianum variegatum*, yellow, edged with green, and *Trifolium repens rubrum* with chocolate foliage edged with green. Mr. Ware also received an extra prize for a pretty collection of herbaceous plants, in which were several with ornamental foliage, the pretty white *Phlox Nelsoni*, the rose-coloured *Phlox setacea*, *Cheiranthuses*, *Anbrietias*, *Lithospermum fruticosum*, which attracted every one by the intense blue of its flowers, *Trillium grandiflorum*, *Dodecatheon elegans*, *Iris pavonia*, and many others.

Messrs. F. & A. Smith, Mr. Watson, and Mr. Shenton sent variegated Zonal *Pelargoniums*, of the *Tricolor* and *Gold and Bronze* sections; and Mr. Mann, Brentwood, his splendid scarlet-flowered variety, *Lord Derby*, which fully maintains the high character which has been given of it in previous reports; also trusses of *The Baron*, a showy crimson scarlet *Nosegay*. A collection of *Gloxinias* came from Mr. August, Beddington; and from the Society's garden at Chiswick a large collection of *Palms*, *Dracenas*, *Pandanads*, and other plants with ornamental foliage, and the new *Caladiums* raised by Mr. Bause. The leaves are pale green, with a strong golden tinge, and are variously marked: in one kind with crimson, in another with white and crimson spots, and in a third these are seen on a silvery ground. These varieties, one parent of which was *Caladium bicolor splendens*, will, doubtless, attract much attention as they become more fully developed, and they promise to become charming additions to our ornamental-foliaged plants. There was also from Chiswick *Anthurium Scherzerianum* with seven fine spathes.

RED BEET AS A FLOWER-GARDEN PLANT.

I AM sorry I am not acquainted with the variety of Beet of which my friend Mr. Perkins gave an account in page 421 of your last volume, neither can I lay claim, I fear, to being the first to call attention to this plant for flower-garden decoration. Twelve years ago, or more, when the beauty of the foliage of certain plants, as *Dracenas*, *Crotons*, and *Marantas*, became fairly acknowledged, I urged, it is true, the claims of plants of a humbler class as deserving more attention than had been paid to them, and mentioned the *Globe Artichoke*, *Fennel*, *Red Beet*, coloured *Kale*, *Carrots*, and *Parsley*, and suggested that an effective striped border (the term ribbon border not having then been invented), might be composed of these plants, as each of them might be considered likely to last the season. I must confess to not having used the Beet so much as it deserves, in consequence of the variety I had, though good for salads and culinary purposes, having a propensity to run to seed at the precise time at which the other occupants of the same bed were at their best, and instead of the graceful, recurved, and flowing foliage, a few small pointed leaves were all that was left when the seed stem was removed, and removing one seed stem only induced the plant to produce more; otherwise I must admit that when at its best nothing can well exceed the glittering beauty of Beet when of a good colour and looked at in sunshine. I have found, however, from the limited trials which I have made, that this period of perfection is of short duration; therefore I have mostly used another plant—*Perilla nankinensis*—which I fear Mr. Perkins

will think a sorry substitute for Beet, yet it is not destitute of merit.

The *Perilla* is most extensively grown here as a dark-leaved plant; and although *Coleus*, *Iresine*, *Amaranthus melancholicus ruber*, and Beet may all be better than *Perilla* when at their best, their services are either obtained at a greater cost as regards potting, or they are of shorter duration. The *Perilla* may, without much trouble, be grown to show a tolerably good line by the 1st of June; and that line may be kept trimmed to a height corresponding with neighbouring plants until the end of the season, say the middle of November, and will look well the whole time, as there are comparatively few plants which furnish such an abundance of foliage on specimens struggling continuously into seed. Some plants will succumb altogether when the flower stems are continually cut off. Even perennial ones do not always like to have the intentions of Nature frustrated in so persevering a manner, and in this way great losses are met with in the case of *Centaurea gymnocarpa* and other plants; but the *Perilla* seems to endure cutting-in almost as well as grass itself, and when viewed at the distance of 50 or 100 yards its appearance is very often as good as that of the *Coleus*, and very much better than that of the *Iresine*—in fact, the latter has been so often a complete or partial failure, that it will only be used in future in places of secondary importance.

I may state in favour of the *Amaranthus*, which in 1867 did very well here, that it has the richest appearance when looked at with the face of the observer to the sun. This is exactly the reverse of what happens in the case of many other plants. Those, therefore, who have their flower beds on the south sides of their principal walks or lines of vision may safely plant *Amaranthus* if other conditions be favourable, as the semi-transparent character of the leaf allows so much light to shine through it as to show the rich colouring to great advantage. On the other hand, many flowering plants—the blue *Lobelia*, for instance, look best when viewed the reverse way, as so many open to the sun.

To return to Beet as an ornamental plant. As a variety has been pointed out which can be sown in March, and yet does not run to seed, we have in it a great acquisition for flower-garden decoration, as Beet can be transplanted as well as most plants, and, as Mr. Perkins says, is both ornamental and useful afterwards. A friend of mine in Hertfordshire, who grew it as well as the *Coleus*, *Amaranthus*, *Perilla*, and *Iresine*, during the past season, affirms that it excelled them all. The best examples that I have met with, I saw in Yorkshire some years ago; but, as I have before observed, merely looking once at a plant when it is at its best, is not a sufficient knowledge of it to justify unqualified praise. I once knew a lady in raptures with a bed of blue *Nemophila*, but she was not, perhaps, aware that its display extended only over six or seven days. That Beet will remain in beauty longer than that there is no question, but whether for both early and late display it can be depended upon to continue good, is more than I can decide. That it will be useful for its foliage late in the season I know, but where as much bloom and colour as possible are wanted before the 1st of August, or say from June 1st to that period, what experience I have hitherto had with Beet tends to prove it is not so much to be depended on as the *Perilla*.

Mr. Perkins justly calls attention to the utility of the foliage of Beet for embellishing the dishes of the dessert, and I can fully endorse all he says as to its merits in that respect; but there is also another plant of which the utility of the foliage for the dessert has never been fully recognised, although I have known it employed for the purpose as much as thirty years ago, and that is coloured *Kale*. The best variety is the white, as the rosy purple kinds, however rich and pretty in daylight, do not look well at night. The Beet in foliage is no mean competitor to the exotic *Dracena*, and if when gracing a flower stand it should be mistaken for a new *Calla* or *Caladium*, what matter? Ought beauty when combined with utility and simplicity to be condemned because of the two latter qualifications? Assuredly not, rather let us carry the matter further, and see if other useful plants do not furnish us with forms that may be turned to account. I have on more than one occasion seen a half-blanced half-dead leaf of a very common plant take a place with great advantage in a bouquet, and the reader will be more startled in this second case than in the former, for the plant was the common *Carrot*. Yet it is so. In a *Carrot* bed may be met with leaves of a rich orange colour, having all the Fern-like character of fresh ones. I hope to hear more of Mr. Short's Dwarf Beet, and if it do not run to seed during the summer after being sown so early, it will probably be more

extensively grown than has yet been the case, and for one I should like to try it.—J. ROBSON.

[In the kitchen garden at Wollaton Hall, near Nottingham, there were last year borders of Dell's Beet, which, when we saw them in September, were very effective, and, as Mr. Robson remarks, their produce was useful as well.]

VERBENAS.

As an admirer and grower of the Verbena I beg to tender my best thanks to Mr. W. Dean for his notes on Mr. Perry's new varieties to be sent out during the present spring, and for his excellent list of older sorts. I can fully endorse the high character which he gives them.

It is difficult to imagine anything finer than such superb varieties as Miss Turner, Hercules, Mrs. Mole, &c.; the first-named variety especially, with its large, bold, and handsome truss of finely-formed flowers, must, I think, be regarded as the very best light variety ever offered.

I wish Mr. Perry would kindly give us through the pages of the Journal his mode of growing the Verbena for exhibition; I am sure he would have the best thanks of all growers of this fine flower if he would give us a thoroughly detailed account, and also his mode of raising seedlings. I have found some difficulty in inducing the seed to germinate when sown in heat, and have this year sown a small quantity saved from such finely-shaped flowers as Snowball, William Dean, Mrs. Turner, &c., and placed it in a cool greenhouse, with what results remains yet to be seen.

It has been stated that the seed is more certain of germinating when sown in the open ground, but I fear by this system the seedlings would bloom very late, and it would be difficult, perhaps, to judge what were worth proving in the following year.

It is a matter of regret that this fine flower does not receive more encouragement at our leading exhibitions, for, with the exception of the Crystal Palace Autumn Show and a few others, the prizes offered are very small; framers of schedules would do well to look to this, for few cut flowers, or indeed any flowers, have a finer appearance than a good stand of twelve or twenty-four varieties in three or five trusses each. In my opinion it is quite absurd to give £5 or £10 for a collection of, perhaps, half a dozen greenhouse plants and as many shillings for a stand of Verbenas, as is done at a great many of our autumn shows; for I have noticed that where really good cut flowers, such as Roses, Gladioluses, Verbenas, &c., are shown they have crowds of admirers where the plants receive but small attention, although exhibited by some of the best growers, and I think it is quite time we had a fairer division of prizes in our schedules.—E.

AURICULAS.

I SEE that your reporter takes exception to my statement as to the time of showing these plants. May I be permitted to justify my statement by saying that no argument can be adduced from last season, as I never recollect such a season since I have been an Auricula grower? and I think I can appeal to any Auricula fancier in the south of England as to whether the general time of their being in perfection is not from the 15th to the 30th of April.—D., Deal.

ENTOMOLOGICAL SOCIETY'S MEETINGS.

The April Meeting of this Society was held at Burlington House, H. W. Bates, Esq., the President, being in the chair.

Mr. Stainton exhibited some leaves of *Euphorbia dendroides*, just received from Mr. Moggridge from Montone, which were mined by larvæ of a minute moth (*Nepticula euphorbiella*), specimens of which had been recently reared from larvæ collected in the early part of last summer at the same place. Mr. Stevens exhibited the insect which had served Mr. Stainton in 1851 for the description of his new species *Neophora Carteri* (formerly in the collection of Mr. Carter, of Manchester). A recent examination of the individual had proved it to have been fabricated, the hind wings of a *Cerostoma* having been attached to the fore wings of a *Neopteryx*. Mr. Boyd exhibited a strongly-marked dark variety of *Stenopteryx hybridalis* from Hertfordshire. Mr. Druce exhibited a collection of Butterflies obtained by Mr. Pearson in Bolivia, including the very rare *Papilio zagreus*, &c. Mr. Weir exhibited a *Polioptamus*, captured at Lewes, which he regarded as a hybrid between *P. Adonis* and *Alexis* also *P. Corydon*

and *P. Alexis*, with the spots on the under side of the wings confluent and a male-like female of *P. Alexis*.

Mr. Smith stated that in the collection of insect productions in the British Museum was a portion of a pollard Oak, sent there three years since by Mr. Kidd, exhibiting a great number of the gall nuts. It had been placed in a box with a large lump of camphor, yet each succeeding spring there had been reared from it a number of individuals of *Clytus Arietis*, on which, whilst in the preparatory state, the camphor had had no effect. Mr. Janson said that camphor, though useful in preventing the entry of insects, was powerless to destroy them; at the same time he doubted whether the *Clytus* had been reproduced by breeding in the Museum, considering that the larvæ of the beetle were in a more or less advanced state when the block was received at the Museum, and that the successive broods of 1866, 1867, and 1868 (for one specimen had been produced on the morning of the Meeting), had been hatched from eggs deposited in 1865 or in previous years.

The May Meeting was held on the 4th inst., presided over by H. J. Stainton, Esq., Vice-President. Amongst the donations received since the last meeting were the publications of the Linnean, Royal, and Royal Agricultural Societies, the Royal Society of Brussels, the Imperial Society of Moscow, Messrs. Vollenhoven, Hewitson, and Sir John Lubbock, &c. The most important of these works was the first part of the Catalogue of Scientific Papers (arranged alphabetically), published by the Royal Society, which, when complete, will extend to from twelve to twenty quarto volumes.

Mr. Boyd exhibited a number of carefully-preserved caterpillars of different British species of Butterflies and Moths, and Mr. Trimen a specimen of the Emperor Moth (*Bombyx pavonia minor*), which had died in attempting to escape backwards out of its cocoon. Mr. McLachlan exhibited specimens of the fine Dragon Fly, *Anax mediterranea*, which had appeared in large swarms in Italy, received from Signor Ghiliani, of Turin. Mr. F. Smith exhibited a caterpillar of one of the Staphylinidae, found underground by Mr. Janson, jun., which had been destroyed by several parasitic larvæ of a species of *Proctobrupe*, the pupæ of several of which still remained in an undeveloped state attached to the ventral surface of several of the alternate rings of the body of the victim.

Mr. Stainton called attention to a well-executed plate contained in the first volume of the Memoirs of the Academy of Sciences of Paris, published in 1750, in which were represented the transformation of a small but curious Lepidopterous insect, which feeds on the Vines in France, belonging evidently to the genus *Antispila*. The caterpillar was remarkable for being entirely destitute of legs, but no further information beyond the plate in question had ever been obtained or published.

Mr. F. Smith exhibited specimens of three kinds of insects injurious to timber trees in India—namely, *Cerostoma gladiator*, a Longicorn Beetle, which attacks the bark; a large Acheta or Cricket, which makes its appearance in large numbers in September after the rains, and gnaws off the young shoots of *Casuarina* trees when they are two or three lines thick; also specimens of the Borer Beetle, *Clytus quadripes*, the larvæ of which bore into the trunk of Coffee trees. Mr. Trimen stated that a large species of Cricket at the Cape of Good Hope also eats off the young shoots of the Silver trees. Dr. Wellan sent for distribution a number of eggs of the *Bombyx Yama-Mai* or Oak Silk-worm of Japan. A note was read from Mr. Hewitson on the synonymy of a species of Pieridian Butterfly from New Caledonia.

A paper by Mr. Desborough on the duration of life of the different members of the hive was read. The author had succeeded in ascertaining that in certain cases the queen bee will survive and deposit eggs during not fewer than six seasons, whereas the worker bees only live about eight months. A single queen had produced as many as 108,000 eggs, which would be about 20,000 a-year; but the greatest amount of eggs was deposited during the first two years of her life, only about 15,000 being laid during each of the last three years.

Mr. F. Smith read descriptions of a number of new species of Hymenopterous insects, sent from Champion Bay, Australia, by Mr. De Bonlay, more than half the specimens collected by that gentleman having proved to be undescribed. He observed that it was remarkable that whilst the leaf-eating bees were numerous in New Holland, he had never seen one of their usual parasites belonging to the genus *Cichoxys* from that country.

Lieut.-Col. Taylor sent for exhibition a number of specimens of seven different kinds of insects and larvæ which attack the Coffee plant in Upper India. Capt. Taylor, who was present, gave an account of the ravages of these insects in Koorag and Ceylon. The subject led to an extended discussion, and was ultimately referred to a committee to draw up a report on the subject. Two new parts of the Society's Transactions were upon the table.

FLOWER POTS.

INQUIRY is often made as to the best form for garden pots, and in reply I wish to tell that I brought a few from Dieppe some time ago, which I like better than any other which I have seen, yet, I think, they may be improved on. This is

the shape. (See *fig. 1*.) You will perceive there is great strength where it is most wanted, and that the pots will fit into each other without sticking fast. Indeed, with a stake

Fig. 1.

Fig. 3.

Fig. 2.

run through the holes they would form very strong and neat pillars in the garden when not otherwise in use, and be out of the way, instead of being an eyesore. *Fig. 2* is a representation of a pillar formed in this way.

It appears to me, however, that by having a portion of this thickness at the shoulder taken off on the inside you will improve the form materially, as is represented in *fig. 3*.

In this form you have a chamber for the drainage, a wide bed for the roots, promoting surface-rooting, space for mulching and watering, and a form which easily admits of the plants being turned out, and the external form and strength are retained.

I find it very convenient to use an apparatus like a crinoline, which is easily made by a piece of muslin thrown over a frame, for fumigating individual plants when I do not want to close the whole house. I put it over the pot so as not to touch the plant, and place a pan of lighted tobacco-paper under it. I also use it for standard Roses.—D. S.

[This communication will afford to "AN AMATEUR," "MYRA," and other correspondents information on which to form their own judgments in answer to their variously expressed query, "Which is the best form of flower-garden pot?"]

The inventions to satisfy various requirements in such pots have been numerous, but we do not know whether they can now be purchased, for with rare exceptions they have that fatal characteristic—dearness. The following are some of them, published in one of the earliest of our volumes:—

To facilitate draining, and yet to retain the tidiness secured by the saucer, Mr. Hunt has had flower pots made (*fig. 4*), with elevations, on which the pots are placed. But this is not the only advantage derivable from them. They prevent the entry of worms, may be employed with common stands, allow a current of air to pass beneath them, and their form is elegant.

Mr. Brown has proposed a pot (*fig. 5*), with hollow sides, the

Fig. 4.

Fig. 5.

Fig. 6.

vacuity to be filled with water through a hole in the rim, or left empty, as occasion requires. The water, he considers, will prevent the plants suffering from want of moisture; and when empty, the roots will be preserved from being killed by evaporation. But surely applying the water to the sides will be an extra inducement for the roots to gather there, an effect most desirable to avoid, and wetting the outsides of the pot is a very doubtful mode of preventing the reduction of temperature.

Saul's fountain flower pot (*fig. 6*), seems open to the same objections, with the additional disadvantages of not being easily drained, and being more expensive and cumbersome. The water is also forced in at the bottom of the pot, contrary to the course of nature in applying moisture to plants. "An outer basin is made on the bottom of the pot, to which the water enters at *a*, and is carried round the pot in the basin, there being two or three holes through the pot's bottom, *b, b*. By these means the water is drawn up from the basin by the roots of the plants, or, if it should be desirable to prevent it from being drawn up, the exterior orifices of the holes, which open into the basin or saucer, may be closed. The fountain is supplied with water by taking out the stopper at *c*, the entrance into the basin at *a* being at that moment closed; and as soon as the water runs over at *c*, the cork or stopper is put in, and the stopper at *a* removed."

Mr. Stephens's flower pot (*fig. 7*), is intended to supply water to the plant where it is most wanted, and to protect it

Fig. 7.

Fig. 8.

Fig. 9.

at the same time from slugs and creeping insects, which will not pass over the water between the two rims.

Mr. Rendle, of Plymouth, proposed to improve the drainage of pots by elevating and piercing their bottoms. This, and Mr. Brown's, suggested to us that of which *fig. 8* is a section. It is merely two pots, one fitting within another, having the bottom indented and pierced as proposed by Mr. Rendle, but not touching the outer pot by half an inch all round. This is a most effectual form to secure drainage, and to prevent the evaporation from the sides of the inner pot, the intervening stratum of confined air being a bad conductor of heat. It has the merit, too, of cheapness.

Another pot (*fig. 9*), adopted by T. C. Palmer, Esq., of Bromley, Kent, has been found by him to have the advantages that it induced worms to pass out, yet prevented their return; was very effectual to keep out ants, slugs, &c., as it stood in a saucer of water without any excess of moisture reaching the soil; and from this quality might be particularly suitable for Heaths.

One of the inconveniences attendant upon pot-culture is the hardening of the surface soil by watering. This may be obviated by having the rim of the pot (*fig. 10*), encompassed by

Fig. 10.

Fig. 11.

a gutter, *a, a*, communicating to the earth within the pot by numerous perforations, *b*. Water poured into the gutter would thus gently percolate away into the earth.

Fig. 11, is a form that is useful for facilitating the shifting of specimens in large pots. It was patented, we believe, by Mr. G. Fry, formerly gardener at Lee Park, and named by him the "West Kent Garden Pot." The drawing represents a section of it. The pot is without a bottom, the orifice *b* extending across its entire diameter, except a narrow ledge all round, on which rests the false bottom, *c*, perforated as usual with the drainage hole, *d*. The principal advantage of this form is that at shifting time, a block of wood of the size of the orifice *b*, being pressed up, it moves the ball of earth bodily, thus disturbing the roots as little as possible.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

EVERY showery day should now be taken advantage of to plant out young crops, to thin and prick out others, and to look

diligently after slugs and snails. Every moth and butterfly should be as carefully destroyed as wasps. *Broccoli*, *Cauliflowers*, and other plants of the Cabbage tribe from the early seed beds may now be planted for autumn use. *Cucumbers* and *Vegetable Marrows*, prepare for planting these out, forming beds of short grass, refuse from Sea-kale beds, &c., or any other littery rubbish, but in exposed situations a week or ten days hence will be soon enough. *Peas* and *Beans*, after having pinched out the tops of the first crops of these give a good watering, and if any sort of liquid manure is employed all the better, but do not use hard spring water if it can be avoided. *Potatoes*, the early ones will now be forward enough to have the soil well stirred between them, like all other crops in rows. *Succession crops*, in all their stages, will now show if the sowings have been judiciously timed. Endeavour to mark out any probable defects, and, if practicable, lose no time in rectifying them. *Tomatoes*, *Capsicums*, and all half-hardy plants for the kitchen garden, may now be planted out in early and favourable situations; but in cold exposed places a week or ten days will suit them better.

FRUIT GARDEN.

All the trees on the walls will now require close attention. The system of nailing as many of the strong young shoots of Pear trees as possible between the main branches is good, and if it is not desired to leave them to bear, the grower may begin to reduce them after the end of July. Peach trees, like Melon plants, are very apt to get into confusion about this time, unless they are carefully thinned. Formerly wall trees seldom had much attention paid them till all the breastwood was nearly full grown. They were then regularly pruned, and you could see where the pruner left off at night as plainly as where mowers had left off cutting a piece of meadow grass; but now a man in looking over his trees only cuts out a few shoots here and there at a time, and in this way he soon goes over a large number, and when he has gone round, some of his trees will want looking over again. Some gardeners adopt the practice of pinching out the tops of the young shoots of Pear trees when from 4 to 6 inches in length, and this proceeding is repeated during the season. It is recommended, because there will be no danger of the lower buds breaking, no sudden check will be given to the system, no unnecessary shade afforded to those parts which ought to be fully exposed, and if persevered in, and the tree is otherwise favourably situated, there will be little occasion for resorting to root-pruning.

FLOWER GARDEN.

Multitudes of tender plants have, doubtless, been planted out, and as the weather has been as ungenial as it can be for such operations, nothing but assiduous attention to watering and shading can give them a chance of success. The importance of properly mulching the beds cannot be too much insisted upon, and where it is inconvenient to use short grass because of its untidy appearance, the beds should be surfaced an inch thick with leaf mould or fresh light soil, and where neither can be used hoe the beds over so as to produce a loose surface. Mulching is advantageous, not only from saving labour, but also, where cold spring water has to be used, from preventing the soil from being unnaturally cooled by the frequent application of water from a cold medium. The importance of using water as warm or even warmer than the soil is well known to practical men, and a few experiments will soon satisfy the amateur of its advantages. After planting out, make a reserve of a few plants of each kind to fill up gaps, and also if you fill any beds with annuals reserve some plants in pots to replace them as soon as they become shabby. The "worm" of the bud" amongst Roses is making considerable havoc in some places. Look carefully over the plants, and destroy the maggot between the finger and thumb; regulate the growth of the plants at the same time. Seedling *Anticulas* may now be pricked out into pans or boxes of leaf mould and sand, at regular distances, keeping them in a close frame for a few days till they have taken fresh root, when they may be placed in the shade and protected from drenching rains. *Ranunculuses* are now growing fast, but are much in want of rain. If they have been top-dressed with very rotten manure, they will in some measure have escaped the effects of the drought. As *Carnations* continue to grow keep them regularly tied up to their flowering stakes; the pots must also be well attended to, all weeds must be removed, and the plants top-dressed. Continue to remove luxuriant shoots of *Pinks*, and thin the buds, removing those which are small or malformed. Both *Pinks* and *Carnations* are now much infested with insects, these must be carefully brushed off; avoid bruising them on the buds or stems

of the plants, as it appears to have a prejudicial effect. *Dahlias* may now be planted out with safety.

GREENHOUSE AND CONSERVATORY.

With the exception of the routine of watering and syringing, the next matter of importance to greenhouse plants now in active growth is to form them into handsome specimens—some by training, others by pruning, or rather stopping, and all by being kept in a vigorous healthy state. One of the greatest faults committed against young promising specimens is to let them flower too early. If the plant is quite new there is no resisting this course, but in all other cases avoid it as much as possible. In the hurry of watering it often happens that the centre of the balls of large specimen plants, *Orange trees*, &c., is allowed to become very dry, the water finding its way down near the outside, where the soil is looser. Gardeners on the Continent make a provision against this, which we seldom see done in this country. They scoop out a little of the soil round the stem, and raise that towards the edge of the pot or tub, thus forming a shallow basin, so that a large portion of the water passes down the centre. In summer this is a good plan for many plants, and in winter the surface could be levelled over in the usual way. Do not be in a hurry to turn out of doors fine greenhouse plants; but all coarse and common plants, and many softwooded plants whose tops in a manner may be considered to be annual, may be turned out any time about the end of spring, and the finer portions of the plants will by this means have all the room, light, and air to themselves. Of all plants those in the greenhouse are most apt to become too dry in summer; and therefore, besides the regular watering, they may be syringed every afternoon in fine weather.

STOVE.

Many stove plants would do better in an intermediate house from this time till the end of August, where they would suffer less confinement than in a regular stove. For want of such a house gardeners often make use of vineries, &c., for this purpose, and distribute their stove plants in summer through the different forcing houses; and if only for the benefit of finishing and ripening their growth without being crowded, this is a good plan. Air, moisture, and cleanliness are now such matters of course that they need not be insisted on.

PITS AND FRAMES.

These are applied to so many purposes from this time to next September, that no calendar can anticipate the different treatment in all cases. Where plants are more an object than fruit, cold pits are the very best places for *Heaths* and all delicate greenhouse plants. A mixed greenhouse is an indifferent place for ripening-off the growths of *Camellias* and Chinese *Azaleas*, two tribes whose flowering next year depends on the treatment they receive at this time. Close pits shaded in the middle of the day, and kept moderately moist, suit them best.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Seeds.—As our first-sown vegetable seeds either will not come up as we want them, or, in despite of our netting, the birds have found their way in and have taken the lion's share, we levelled and made fine a border and covered it with hand-lights from the early *Cauliflowers*, sowed the seeds under the hand-lights, and, after watering, covered up with mats. We set the lights in double rows some distance apart, so that the seedlings will have room to extend laterally, and this plan will at least secure everything like fair play to the seeds, and give us a fair return if they are, as we feel tolerably sure they are, all right on the whole. A very little matter often makes a great difference in seedlings, and of all things nothing is more injurious to them than extreme dryness just when vegetation has commenced. From this cause alone we are able to decide why one pot of seeds never comes up and another pot of seeds from the same packet comes up as thickly as grass on a lawn. We may here mention, that when scarce of some seedlings of favourite vegetables, we have had fine returns in going over the best kinds of Scotch Kale, for instance, and taking off side shoots, strong ones, with a heel close to the older stem, planting them and watering them just as if they were strong young plants. Some of these might throw up a flower stalk, which was cut off, and fine, strong, producing plants were the result.

Cauliflowers.—Banked-up the forward *Cauliflowers* with dung from old Mushroom beds, and covered the ground with litter

to keep the moisture in. The plants are strong and looking as if they would form large fine heads, which we always regard as one of the finest sights in the garden. The second crop had the ground stirred among the plants, and a little water was given at the roots. A third piece was planted with young plants, previously pricked-out and hardened-off, raised with balls, and set in shallow trenches in rows 2 feet asunder. We waited until Saturday to do this work, as the atmosphere was more cloudy, and there was promise of showers, at least before long. Such plants would have had a poor chance without shading in the scorching sun of the previous days. Much of success in all departments depends on plants suffering as little as possible when changed from one position to another.

Beet.—The most forward is coming up well, and we had to net immediately, for the birds as usual were on the watch, and would have destroyed every seedling as soon as it showed the red leaves.

Asparagus.—Planted a piece in rows 2 feet apart, in ground well turned and prepared previously. We generally spread out the roots on the well-broken surface, turn over the soil on the roots from the spaces between, so that the ground forms a somewhat flat ridge above the roots, and then cover with 2 or 3 inches of old Mushroom-bed dung, or other rotten manure. Some grass mowings, thrown in a heap to heat and kill all Daisies, &c., are also a good mulching for Asparagus in summer. Except for protection, the manure given in winter is of little use, the help should be applied when the Asparagus is growing. A little sprinkling of salt twice during the summer is also useful. We allow the Asparagus generally to take its own way for two seasons. This season old and young plants came quite in a rush, and had we known it we would have planted a week earlier, when the plants were only a little above the ground; but as it is, though many plants were 6 inches in length and some longer, they never suffered after being planted and watered. This was chiefly owing to the roots being kept moist in a barrow, covered with a mat, and sprinkled so that no fibres were dried up by the sun. Such plants would not be suitable to send to long distances. In all stiff soils, and where thorough open drainage cannot be given under each bed, such surface-planting and surface-manuring are more important than trenching and manuring to great depths. The deep covering of the roots is one cause of failure, or comparative failure, in stiff soils. Without great preparation we could not rival the productions from the deep light soil of Battersea, but any one may have a few rows of Asparagus in his little garden without going to the wondrous outlay that some recommend in forming a bed. Even in stiff soils the roots will do well if kept near the surface and mulched on the surface.

Cucumbers and Rats.—Since those unwelcome visitors—rats, cut down our Kidney Beans we have seen little of them, and we somewhat prematurely hoped they had left us for a time; but the other night they made their way into our pit and gnawed a number of our best Cucumbers, and bit and mangled some scores of young ones, many not more than 3 or 4 inches long. We have failed to discover their retreat, and must, therefore, confine ourselves to trapping and poisoning them, though the latter is much against our will. The last corn stack built on the ground in our neighbourhood has been taken down and threshed, and now we expect to suffer from rats for some time. As yet the rats have contented themselves with the fruit of the Cucumber, and have not touched the shoots.

FRUIT GARDEN.

Strawberries.—Hoed the ground again among Strawberries, that every little weed might be killed if there were any, and also to keep the surface loose to let the rains in when they come. Will try to strew the ground with a little quicklime previously. Some Black Prince and others turned out of the houses have taken fresh vigour and produced some high-coloured good fruit out of doors. Those swelling and ripening under glass had a little superphosphate of lime placed on the surface of the pots to help them, just as much as could be conveniently taken between the thumb and the fingers. Every watering will wash the virtue to the roots. There is not much danger in giving an over-dose of this. It does very well mixed with water, 2 ozs. to the gallon, and comes in as a change between clear water, soot water, dung water, &c.

Orchard Houses.—Considerably, but not fully, thinned fruit on Peach trees, &c., which were of just a fit size for tarts. Observed a few appearances of the brown aphid, and syringed those trees with quassia water; the rest of the house in sunny afternoons we syringed with clear soot water and clear common water alternately. The Little Gem Pea in pots has produced

more abundantly than we expected at first, and the flavour is good. In the latest orchard house the syringing has as yet kept all in good condition. If the hot sunny weather should continue we will boil some soft soap, rather strong, make a paint with it and flowers of sulphur, and daub the open places of the wall with the paint. This, and frequent syringings with clear soot water not over-strong, are great preventives to the attacks of red spider and other insects. Plums, Cherries, Peaches, &c., are swelling well. Soft soap of itself is a great enemy to all the insect tribes, and may be used for syringing when the fruit is young, but never after Peaches are much larger than marbles, as after that it is apt to affect their downy skins. It is best applied thus:—Take 1 lb. of soft soap, boil it in a gallon or two gallons of water, and let it stand covered up in a pail for a number of hours. Then pour it off carefully into twenty or twenty-five gallons of pure soft water at about 90°, allowing any sediment to remain, and this liquid, though soapy and unctuous, will leave no residuum, unless on Peaches too far advanced, whilst it will prevent all insects from freely using their breathing powers. When insects appear in small places it is well to use the powdered tobacco of Mr. Pooley and others, and syringe with clear water next day. We have little faith in any killing and cleaning after plants become very much affected, the great point is to keep insects from coming.

Most of the Strawberry plants removed from under glass have been planted out, which saves watering them when standing about in pots, and secures a fair autumn crop without interfering at all with wondrous crops the following summer. What is planted out late can yield little or nothing this autumn, but there is no other plan that will beat these forced plants for yielding crops the following season. That first crop in the open air will be the best, that in the second year will not be so good, and the third crop will in general be very poor. When the plan is followed, only two crops should be taken after the plants have been turned out.

Proceeded with tying Peaches, thinning Grapes, &c., and kept the floors moist in these parching days. Prepared some dung beds for frames and Melons, making them at once, and putting earth in immediately, as previously stated, and will plant in the beginning of the week, when the earth will be sufficiently warmed. Washed a Peach wall with soft soap water, as green fly had begun to make its appearance. We prefer made soap water to that from the washhouse or laundry. Could we get the latter we should prefer it for watering at the roots. When strong shoots now appear on Peaches, Apricots, &c., stopping-back may be useful for causing two or three shoots to fill up a vacancy, and the sooner the stoppage takes place the better will these secondary growths be ripened. If only one shoot is wanted, the strong shoot should be stopped, and after the secondaries have grown a little one of them should be selected. Extra strong shoots are to be avoided in all such fruit trees, as they rob the weaker shoots of their due portion of matured juices, and grow too vigorously themselves, to be so ripened in our climate as to prove fruitful. The first proceeding of the cultivator should, therefore, be to remove, or early to stop all such over-vigorous shoots, in order that the strength of the tree may be equalised throughout. Our aim should be to obtain wood not over-strong, nor very weak; but even a weak, well-ripened shoot is preferable to a very vigorous one imperfectly matured.

ORNAMENTAL DEPARTMENT.

Heartsease have had a favourable time in the sunny weather. Viola cornuta seems almost as sweet as, and to us is more pleasant than the Russian Violet. Tulips will now be in their glory, and the fine florists' kinds should be protected at least from heavy showers and hail, which may yet come, as on the 7th we had ice the thickness of a pennypiece, though the day before and the day after were excessively warm. On Saturday morning we had rumblings of thunder in the distance, and clouds less or more all day, and we uncovered all our bedding plants, expecting the rain that did not come. The wind being nearly due south we left all uncovered for the night, resolving to roughly cover in the morning, if no rain came during the night, as they were becoming too dry to stand a bright sun long before they were watered, which we were unwilling to do until we saw what would come to us from the clouds, the best of all watering. Much time has been taken up in potting Ferns and other plants intended for the open ground, the greenhouse, and other houses, so as to bring them on rapidly, the contest beneath every foot of glass now being, whether that foot shall be devoted to the eatable or the ornamental, or to both. For instance, no sooner do we plant Cucumbers or Melons, than

the backs and fronts of pits and frames are generally devoted to other young plants, which are just removed as the room is wanted—a way to make the most of the glass, but which involves much time and labour, and a considerable amount of contrivance, so that the plants shall not suffer from the change.

Watering required much attention, not so much as to quantity given as to discretion in giving it. To newly potted plants, and even those partly or wholly established, it is of little use to flood the roots, when these roots are already surrounded with earth quite moist enough for them to absorb moisture freely. In such cases a damp atmosphere, from damping the floor, stage, and even in many cases syringing the foliage gently, and shading in the brightest sun, will be better appreciated by the plants than deluging their roots, already damp enough, with water. When obliged to water, the water should flow over the surface of the pot, and not be poured into a hole close to the stem of the plant, one of the most effectual means for killing outright many plants that are at all sensitive.—R. F.

COVENT GARDEN MARKET.—MAY 13.

THERE has been very little alteration here. A good attendance both of growers and dealers keeps the demand and supply about balanced. Forced fruit is particularly good, and foreign produce arrives in fair condition. Good old Potatoes command a ready sale at former prices. The quotations for new ones are declining.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

N.B.—Many questions must remain unanswered until next week.

BOOKS (*J. Stead*).—A Supplement to the "Cottage Gardeners' Dictionary" is now printing.

YOUNG MELONS YELLOW AND DROPPING (*J. T. Fike*).—The cause is generally twofold—First, when the soil is too rich and the plants too vigorous, they must waste a little of their surplus strength before the fruit can appropriate it rather than the foliage. The second cause is want of strength in the plant from the fruit being allowed to set too soon. The best remedy for that is to treat the plants as lately detailed in "Doings of the Last Week."

THOMSON'S STYPTIC FOR BURNING (*A. Subserthier*).—The styptic should be applied after the bud is inserted, putting it on the cuts made in the stock, but not over the bud itself. This should be done before the bud is bound up.

CAUSING STEAM IN A VINERY (*T. B.*).—It is always very undesirable, and a great waste of fuel, to cause water to boil in hot-water pipes, and it is a dangerous and bad practice to pour water in a vinery on pipes thus hot. It is safest to use evaporating pans on the pipes, and to sprinkle the floor and the stages to secure atmospheric moisture. The danger of steaming a house from watering pipes thus hot will be in proportion to the nearness of the pipes to the foliage. In a lofty house, when the

plants are a long way from the pipes, the danger will be less. Still the practice is an unsafe one. The vapour that escapes from a small cistern in a house will do no harm. When this matter was referred to lately it was in the case of a correspondent who had a large tank the length of the house. When the Grapes are ripe it would be as well to cover the cistern.

GARDEN PLANS (*Brought-up a Ploughboy*).—Except for a croquet ground we do not admire the arrangement of your lawn and borders. The large circular bed will look very well, only you will have rather much white, having out of the four bands one of *Cineraria* and one of *Cerastium*. A dwarf yellow plant next the gravel would make more variety. Your border round the lawn will do very well; only as it is narrow and will be seen from both sides, it would look as well to have both sides alike—say, plant the centre all round with plants of scarlet *Pelargonium* and yellow *Calceolaria* of the same height, and the two sides with *Lobelia* and *Cerastium* mixed. The broad borders, 4. we would ribbon, keeping the tallest plants next the wall, and for uniformity we would plant the edging the same as the narrow borders. (*Harmony*).—We think a centre and five bands round would be enough for your bed, and we would plant thus, beginning at the centre—*Stella Pelargonium*, *Centauria argentea*, *Amaranthus melancholicus ruber*, *Calceolaria Aurea floribunda*, blue *Lobelia*, *Cerastium*. We break our rule in giving you this advice, as our part is to improve, not to plant.

ORCHARD-HOUSE PLUM TREE ATTACKED BY INSECTS (*E. A. S.*).—From your description we do not know whether you have the brown scale or the brown aphid, *Aphis persica*; but in either case washing with quassia water or soft soap water are effective remedies. If the insect is the brown aphid lose no time about it, as one of the clusters you speak of will soon fill a house if let alone. The largest are very full of blackish yellow matter, and most of these if squeezed will show strings of young ones like ropes of onions. Some years ago we suffered from them, and that has made us look sharply after them ever since. It is safest to keep them away.

SCALE ON PEACH TREES (*W. M.*).—The brown scale on the Peach shoots you must wash off with a hair brush, and use soft-soap water, two ounces to the gallon if the Peaches are still small, but weaker if larger. We cleared a house once by syringing frequently with quassia water, a pound boiled in four quarts of water, and then that increased to five gallons. You might wash the stems alone with quassia water as strong as a pound to the gallon, but that would be too strong to syringe with.

WOOLICE IN CUCUMBER BED (*T. S.*).—All old gardens are more or less infested with woodlice, especially where there are frames and pits and much dung heat. The drier the manure used the more likely will the woodlice be to appear. They like a dry retreat, and from that fact, as often stated, may be derived a lesson as to how to destroy them. If your bed is very much infested water it well, except a few inches in width at back and front, and cover that dry part with a little dry hay. Provide yourself with boiling water and a small-rosed watering pot, and gently turn over the hay in the morning, and sprinkle the woodlice with the water as you proceed. If that is not practicable, take a number of the smallest pots, place a piece of boiled potato in the bottom, and a little dry hay or moss over it, lay the pots on their sides, take them out in the morning, and throw the intruders into hot water, or do as you think best. Woodlice are quite as fond of Melons as Cucumbers.

WOOLICE (*Q. B.*).—Woodlice devour the stems, leaves, and young growths of many plants. As to the means of destroying them see the preceding answer and several of our recent numbers.

STRAWBERRY PLANTS BARREN (*A. B.*).—In your case, if you layered all the plants from fruiting plants, we would attribute so much barrenness to excessive vigour. In such a case we would put considerable faith in the opinion of the gardener, and wait and see what next year would do; but were we in your case and short of ground, we would layer fresh runners and do away with the barren plants. Most likely your plants were too vigorous to be well ripened last autumn.

GRAPE SPOTTED (*E. C.*).—We think the cause of spot on the berries is removing the covering of the outside border too soon, and having too much moisture in the atmosphere of the house from watering Ferns, &c. The reason that the Black Hamburgh suffers whilst the Black Muscat of Alexandria, or Muscat Hamburgh, grafted on it escapes, we attribute to the latter looking after itself and taking the most of the nourishment. It is singular how a graft often escapes the evils that annoy the parent stock, even to making an unhealthy stock healthy.

CYCLAMENS FROM ITALY (*G. H.*).—The Cyclamens found in the neighbourhood of Sorrentum at the end of April, and bright pink, are undoubtedly *C. repandum*, the flowers being brighter in colour than those of *C. neapolitanum*, which flowers in autumn after *C. europaeum*. *C. repandum* is sometimes called *neapolitanum*, *hederaefolium*, and *astivum*. It is quite hardy, succeeding in warm ledges that are sheltered from sun in summer during the hottest part of the day. Cyclamens succeed in a compost of turfy loam, leaf mould, and pieces of grit from the size of a pea up to that of a walnut. The corns should be planted as soon as they arrive, and so that the crown will be covered from 1½ to 2 inches deep. The drainage must be good. If you wish to grow them in pots provide good drainage, and, using the above compost, pot so that the crown will be covered with about an inch of soil. Plunge the pots in a rather shady border out of doors, and do not water but plunge them to the ribs in rough ashes, the pots being set on a bed of loose open rubble. A pot three times the diameter of the corns will be quite large enough. In autumn the pots may be moved to a cold frame, or be left where they are. If placed in a frame they should be plunged, and beneath them should be open rubble, for wet is very injurious to Cyclamens; and not less so is the deprivation of air, of which they cannot have too much when the weather is mild. The soil should be kept moist, but not saturated, otherwise the plants will perish. The best time to repot them is when they are beginning to grow. They may be kept near the glass in a greenhouse, and in the coldest and most airy part, keeping them rather dry in winter. When in growth the soil, of course, ought to be watered so as to maintain them in a healthy state. After the plants have flowered plunge the pots out-doors in a position shaded from powerful sun, and remove them to the greenhouse or frame before severe weather. *C. repandum* is best and most successfully grown on rockwork; it does not succeed well in pots.

CUCUMBERS BITTER (*H. Hopetoun*).—We are not aware that there is any mode of preventing bitterness in Cucumbers, except by growing them

quickly. Cut them when of less size, and give more heat and moisture. The more quickly they are grown the more crisp and less bitter they will be. The stalk end being bitter and the other portion sweet, shows the fruits to be slowly grown and old. Large Cucumbers, unless quickly grown and cut young, are seldom good. The kind may have something to do with the bitterness.

SCABINO ROOKS (E. C.).—We know a place where there are two rookeries close to the garden, and the rooks do not interfere with the crops in the kitchen garden. During twenty years' experience in places where rooks abounded we never had the least trouble or anxiety on their account. So far as we know they do not eat fruit; they do not care for green Peas. We think the devourers of your fruit must be jays, which seldom show themselves during the day, and you say the mischief is done during the early morning hours. Were it done by rooks these would visit you during the day. Your Peas, we think, must have been taken by wood pigeons as well as jays. We would advise you to make sure that the rooks do the mischief before you wage war against them. It would be easy to detect the thieves by rising at dawn, and watching for a few consecutive days. If rooks are the perpetrators, then we would shoot one or two and hang them on a pole as a warning to the rest. It will hardly be necessary to repeat this, only you may drive away birds that you may by-and-by regret.

VARIATED PANSIES (T. L.).—Variegated Pansies are not very unusual, but are not common. The variegation of the plants have been seen was either not permanent or not sufficiently well marked to render them of value as variegated plants. In those we have seen the markings were chiefly yellow.

REMOVING STRAWBERRY RUNNERS (Idem).—Strawberry plants in flower may have the runners removed if you do not require runners for a new plantation, but if you do, the first runners will be best and should be left.

CULTURE OF IXORAS (One Who Loves Flowers).—Ixoras succeed in a compost of two-thirds sandy fibrous peat torn in pieces by the hand, and one-third fibrous loam from rotted turves, adding about one-sixth part of silver sand and charcoal in pieces from the size of a hazel nut down to that of a pea, the whole being well mixed. The compost should be made rather fine, but not sifted. Good drainage is essential. Their proper time of rest is winter, during which they should be kept dry, but not so much so as to cause the foliage to flag. From September to February the temperature may be 60° at night, and from 65° to 70° by day, and 55° at night in severe weather will not be too low. From February onwards the temperature should be slightly increased, so as to have it 65° at night by May, and from 70° to 75° by day without sun, and from 80° to 90° with sun and abundance of air. These temperatures may be continued until September, when they should be allowed to decline.

EPACRIS AFTER FLOWERING (Idem).—It is not right to start Epacris in a stove after flowering; they should have what pruning is required, and be kept in a cool, light, and airy house or pit, and rather moist so as to encourage free growth.

REMOVING PROTECTION FROM FRUIT TREES (J. S. Gordon).—The protection for Plums and Pears will hardly be required after April, as the trees will be in leaf. The fruit is quite as liable to injury from frost as the bloom, if not more so; the protection, therefore, should be kept in readiness for times of severe frost, when it should be employed, and then only. We cannot name plants from leaves.

USING AMMONIACAL LIQUOR IN EVAPORATING TROUGHS (J. B. E.).—Not having tried it for this purpose, we cannot recommend ammoniacal liquor. We think it would answer if diluted with six times its volume of water. We keep our evaporating troughs full of liquid manure made by dissolving 4 lbs. of guano in thirty gallons of water.

HANGING OF LATE GRAPES (A Reader).—As you have sent us no less than three letters we will take time to consider them.

APPLYING GUANO TO A LAWN (H. K.).—Guano should be sown broadcast over the lawn during showery weather so that it may be washed in, for if spread over the grass in dry weather it will brown it. The guano should be sifted through a fine sieve before being distributed. Two cwt. per acre will be a good dressing. Superphosphate of lime may be applied in the same way.

PROPAGATING PRUNUS SINENSIS (W. S.).—This Prunus is readily increased by cuttings. Cuttings of the growing shoots may be taken off after they become hard, inserted in sandy loam, and placed in a hotbed; or cuttings of the ripe wood may be put in during the autumn in sandy soil in a sheltered situation, the cuttings being taken off with a small beel of the preceding year's wood. They will root with certainty and be good plants in twelve months.

VINE LEAVES MILDEWED (J. B.).—The leaf was spotted with mildew. Dust with flowers of sulphur immediately.

CUSTARD APPLE CULTURE (Constant Reader).—For the successful culture of this the house must be lofty, as it attains a height of 15 feet and more. A stove temperature is necessary, and it would be well if the plant had the benefit of a bottom heat of from 75° to 80°. The compost

may consist of two-thirds turf taken from an old pasture where the soil is a good sandy loam, 14 to 2 inches of the upper surface being pared off, chopped in pieces about an inch square; to this add, in equal proportions, one-third of well-rotted cow dung not less than a year old, and leaf mould, and one-sixth of silver or river sand. Good drainage should be given, and the plant ought to be potted rather firmly, giving a good watering, and plunging it in a hotbed. The potting may take place in February, and the plant should have every encouragement to make a good growth by affording it an abundant supply of moisture and increased heat, which should be maintained until October, the plant being then allowed rest by giving a lower temperature and drier soil. A temperature of 80° at night, and from 65° to 70° by day, will be sufficient during November, December, and January, and increase it during February and March so as to be 70° at night by the middle of May, and from 80° to 95° by day with plenty of air. We are not aware that the Cherimoyer has been fruited in this country, and we do not think plants from seed are likely to fruit in a reasonable time. We shall be obliged for particulars as to the culture of tropical fruits in this country, as it is a subject that must, ere long, have attention paid to it.

PEA LEAVES EATEN (G. W.).—The depredator is *Cerculio lineatus*, or pea weevil. The only remedy is to spread a sheet by the side of the rows in the evening, and shake the plants. The weevil retires into the soil during the day, we believe, and comes forth at dusk to feed.

FLOWER GARDEN PLANTING (Man of Kent).—With every disposition to oblige, we must decline to plant groups of beds. Tell us how you propose to plant and we will criticise and point out what we think would be better, if we can. Were we to do as you propose, we should want a staff on purpose, especially for the spring months. We will keep your plan and letter so that we can refer to them when you give us your mode of planting. Your plan is very simple. It would be simpler still if you had no clump in the middle of the lawn, and regular parallelograms all round, with the ends swept out by a curve corresponding with that of a circle between them. Then if you had anything in the centre, a cross or a star would come in better than an oval.

VARIOUS (Idem).—Sow Primulas and Cinerarias to bloom next spring as soon as you can. Pansies sown now will bloom in the autumn and spring. Alyssum, of the perennial kinds for spring blooming, should be struck from cuttings after blooming. Auriculas, Polyanthus, &c., should be divided after blooming, or sow the seeds now. All spring-flowering plants may be divided or struck from cuttings as soon as they finish blooming.

GREEN VITRIOL FOR DESTROYING WEEDS ON WALKS (M. L.).—A pint to four gallons is sufficiently strong. It should be mixed in a well-painted bucket, and applied to the walks with a fine-rosed watering pot, a sprinkling being sufficient. It should be kept from Box or grass edgings, and should be used in dry weather only. In applying it, walk backwards so as not to tread upon the newly-wetted walk, as doing so would be destructive to the boots. It is destructive to everything it touches, so that great care is necessary to prevent splashing, and to keep it only where it is wanted.—G. A.

NAMES OF PLANTS (Subscriber, Liverpool).—We cannot identify a plant from a leaf. (D. Halls).—The same answer applies to you. (A Constant Subscriber).—1, *Anemone nemorosa*; 2, *Muscari racemosum*; 3, *Corydalis bulbosa*; 4, *Dielytra formosa*. (J. S. E.).—*Philadelphus hirsutus*. There is no work treating exclusively on *Selaginellas*. (A. Storrie).—*Libertia grandiflora*. (A. B.).—1, *Erica lachneifolia*, var.; 2, *E. rupestris*; 3, *E. perspicua*; 4, *E. radiata*. (J. H.).—*Sparmannia africana*. (C. H. H.).—1, *Selaginella Galeotti*; 2, *S. Kraussiana*; 4, *S. Martensii*. (Adam).—1, *Selaginella Galeotti*; 2, *Gymnogramma calomelanos*; 3, *Adiantum cuneatum*; 4, *A. affine*; 5, *Gymnogramma ochracea*. (Rolfé).—1, *Cheilanthes hirta*; 3, *Myrsiphyllum asparagoides*. (J. Englefield).—*Selaginella cuspidata*. (A. W. A.).—1 and 2, *Acacia* leaves are quite indeterminate; 3, *Aspidium angulare*. (H. W. E.).—*Staphylea pinnata*. (Elms).—1, *Alyssum saxatile*; 2, *Arabis albidia*; 3, *Andrietta deltoidea*. (E. J. R.).—*Ionopodium scutellaria*. (Mr. Foster).—*Akebia quinata*; it is easily propagated by cuttings of the stem and roots. (F. F.).—Apparently *Sambucus nigra* fol. var. of which there are several in cultivation. (W. Friers).—Not distinguishable from a single leaf. Send a part of the stem. (Ireland).—1, *Forsthyia suspensa*; 2, *Doronicum caucasicum*; 3, *Siphocampylus coccineus*. (E. W.).—2, *Andromeda polifolia*; 3, *Ledum palustre latifolium*; 4, *Leucothoe axillaris*. (A. B.).—1, Double-flowered *Spirea*; 2, *Cytisus supinus*; 3, *Lonicera tatarica*; 4, *Garden Amygdalus*. (Mary).—1, *Arabis albidia*; 2, *Iberis divaricata*. (Spring Flower).—*Lithospermum prostratum*. (A. B.).—1, *Strobilanthes grandiflora*; 3, *Epimedium alpinum*; 4, *Gentiana alpina*. (Subscriber).—We cannot name plants from their leaves. (W. F. R.).—*Alyssum saxatile*. (A. R. C.).—*Ribes sanguineum*; *Prunus japonica flore-pleno*. (W. C.).—*Calcocaria violacea*. (A Subscriber, Glenhaon).—1, *Corydalis lutea*; 2, *Lonicera tatarica*; 3, *Saxifraga hirta*; 4, *Daphne pontica*; 5, *Leucojum vernum* (Spring Snowflake). (G. S.).—*Cytisus* (Genista) *canariensis*. (T. R.).—*Lonicera tatarica*, not wild. (S. H.).—*Prunus* (Cerasus) *padus*. (W. Tyrer).—*Spirea levigata*. (Julia).—*Ranunculus ficaria*. (A. B.).—1, *Nierembergia filiculis*; 2, *Ranunculus acrifolius flore-pleno*; 3, *Epimedium alpinum*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

PRESENTATION OF TESTIMONIAL TO
MR. HEWITT.

On the 12th instant a few of the subscribers to this testimonial dined together at the Public Rooms, Hull, to present it to Mr. Hewitt, and with it an accompanying address. The sum subscribed was just over £400, and it was presented to Mr. Hewitt in the form of a gold chronometer, having on its inner case a suitable inscription, and the balance was in a purse of sovereigns. The chair was occupied by Mr. JESSOP; and the presentation was made by Mr. FLETCHER, one of the Committee, who spoke as follows:—

MR. CHAIRMAN AND GENTLEMEN.—The duty you have done me the honour of placing in my hands I undertake with mingled feelings of pleasure and pain. Whilst, on the one hand, I fully appreciate the honour, I sincerely regret on the other the circumstances which conferred it on me in preference to another gentleman, in every way more qualified than myself. Mr. Jessop, as the originator and principal promoter of the testimonial, the presentation of which has occasioned our present meeting, had the first claim to the performance of my present office, and would, doubtless, have fulfilled the requirements of it with greater efficiency than I can hope to do. We must all deeply sympathise with him in the affliction which has incapacitated him from taking his proper share in these proceedings, and under these circumstances I must ask your indulgence for the manner in which I may acquit myself in the duties I have to perform. Most persons have some favourite pursuit—some hobby, if you please, to which they devote their leisure from the more arduous task which their business, calling, or profession imposes upon them. It is only natural that such should be the case. The mind requires some object on which to unbend itself after the more serious toils inseparable from daily cares, and among the pursuits of this nature none are less exceptional than the effort of improving the quality of domestic animals for the purpose of exhibiting to the public what may be achieved in this direction. It is, moreover, as useful and innocent as it is interesting. It does not admit of the ruinous system of gambling connected with some other pursuits. There was a time when fowls were bred for the purpose of fighting. The preparation of them for exhibiting precludes this use, or rather abuse, of this interesting portion of animated nature. How superior is the presentation of them in their most perfect form and beauty of plumage, to a pursuit which brutalises and degrades the mind and character, need not to be pointed out; it is self-evident. Hence it is a pursuit in which all who have a taste, whether engaged in business or profession, not excluding that of the clerical office, may join; and it is not improbably owing to its unexceptionable character, that it has achieved so great successes. The extent to which poultry shows have advanced is evident to those who remember what they were when first instituted. For instance, the first pen of Game I exhibited, and which gained the first prize, were of different colours—a circumstance which now would amount to disqualification. A corresponding improvement has likewise taken place in their value. In those early days a few shillings or a sovereign was considered an extra price, whereas now as much as £20 or £30 are paid for choice birds. From the nature and object of these exhibitions, the degree in which their success is dependent on the uprightness and intelligence of those whose duty it is to decide on the respective merits of the objects exhibited, and on the confidence his character inspires, must be evident. When, too, the office of judge is filled by a gentleman who unites to a careful study of the subject a judicious and kindly exercise of its functions, contributors derive an important benefit from his hints and suggestions relative to points where improvement should be aimed at. Being thus in advance of exhibitors, he can render them valuable assistance in their efforts to improve the breed of those birds to which their attention is more particularly devoted. The injury that would, on the other hand, be inflicted by an incompetent person, one wanting experience, or devoid of high moral principle, would be incalculable; such an individual ought not to attempt such a duty, or, if he attempt it, ought not to be allowed to exercise it. In Mr. Hewitt we have not only a gentleman combining the necessary qualifications for this office in an eminent degree, but one who in a sense may be regarded as the parent of poultry exhibitions; and the estimate in which he is universally held is a sufficient evidence of the unexceptionable mode in which he has exercised the power entrusted to him, and I feel satisfied that the encomiums passed on him in the address I am about to read will be considered by those I have the honour to address to be well merited. For my own part I most fully and cordially endorse the sentiments expressed in it. But it is time, sir, that I should proceed to the more important part of my duty, and with your permission will read the address which accompanies the testimonial to our esteemed guest.

Address presented to EDWARD HEWITT, Esq., of Eden Cottage, Sparkbrook, Birmingham, in recognition of his valuable services in connection with Poultry Shows.

"DEAR SIR,—The periodical shows for the exhibition of prize poultry may now be regarded as one of the permanent institutions of

the country; and their establishment is justified by the impetus which has thereby been given to the improvement of this department of animal culture—an improvement beyond what is known, save to those practically interested in the matter. Under their auspices the breeding of fowls has become a science. New kinds have been imported, new varieties have been produced, and the value of choice birds has been greatly enhanced. Feeling how much this success is due to your invaluable and unwearied labours, the undersigned hereby desire respectfully to tender to you their sincere acknowledgment of the obligations under which your services have laid them in the promotion of this object. They further request the favour of your acceptance of the accompanying watch, together with a purse, contributed by a large proportion of those, who, as exhibitors or otherwise, are interested in the subject; and they offer it, not as an attempt at the remuneration of your self-sacrificing exertions, but as a slight TESTIMONIAL of the sense they entertain of the uniformly upright manner in which you have exercised the functions of judge in the numerous exhibitions all over the country where you have filled that office, and the unvarying impartiality which has characterised your decisions.

"They are fully sensible that your greatest satisfaction will arise from your own consciousness of the rectitude of your motives; they, nevertheless, feel that it may not be unacceptable to you to know the appreciation in which your conduct is held by those with whose interests you have been so largely entrusted; they, therefore, tender to you this small mark of their esteem for the honourable course which has ever marked your connection with these exhibitions.

"Accept, dear Sir, the sincere congratulations of those who hereby testify their regard, together with their fervent wishes that you may long be spared to continue your useful labours, and that, under an All-beneficent Providence, your advancing years may be attended with increasing happiness."

And now, Mr. Hewitt, it is my pleasing duty to present to you, in the name of those who have been active in the matter, this purse and watch, which are intended as a tangible expression of the kind sentiments and good will to you, and the address I have just read, in which those sentiments are more fully described. I flatter myself, sir, that fully appreciating the intentions of your friends, these evidences of their esteem cannot be other than cheering to you in the labours still in store for you in the cause to which you have been so long devoted. It is the hope of those to whose exertions these testimonials are due, that, in the words of the address, you may long be spared to enjoy the esteem of your friends, and labour in the cause which owes so much to your exertions.

Mr. HEWITT then returned thanks, expressing very forcibly his feelings upon the occasion. He said that this testimonial had attained dimensions which he had never anticipated, and that was no doubt attributable to the influence which the press had exercised. So large was the sum that at one time he was in doubt how to appropriate it; for, having retired some years ago, and being independent of business, he did not require it for any needful purpose. He had received many letters suggesting various modes in which it might be invested. One had proposed a silver candelabrum; but he was fearful that on some occasion when he was absent from Birmingham, judging at some far-distant poultry show, he might on his return find the candelabrum had been removed into Birmingham and converted into some other form. Another proposed a diamond ring; but as he had no weakness in that direction, he declined adopting that suggestion. His own feeling was to convert it into something more permanent and useful than either; and as his present residence, which thirty-five years ago was far in the country, is now absorbed in the town of Birmingham, he had determined to leave it and purchase with this money a piece of ground ten or twelve miles farther in the country, and there to build a house where he would always have around him the evidences of this high mark of the respect which his numerous friends have exhibited towards him.

MR. G. W. JOHNSON then, at the request of the Chairman, expressed the great pleasure he felt upon the present occasion. The list of subscribers was evidence of the high estimation in which Mr. Hewitt's services were held, and Mr. Johnson bore testimony to the same. It so happened that fifteen years since, in this very month in the year 1853, he saw for the first time the awards of Mr. Hewitt at Exeter, and in the July of the same year at the metropolitan show, and then, and ever since, he had seen the same skill and the same uncompromising honesty in Mr. Hewitt's decisions. The press, which Mr. Hewitt had thanked, had but one object in view—the establishment of truth, and in attaining that they had to rely upon the information and aid afforded by such gentlemen as were now present.

MR. TEGETMEIER and the CHAIRMAN then briefly addressed the meeting, after which it separated.

GAME FOWLS.

I READ with considerable interest the article by Mr. Trevor Dickens ("NEWMARKET"), in your number of April 30th, and I readily concur with him in his "dislike of the half-Malay-looking, large, drooping-tailed Game cocks and hens, &c.;" and had he merely expressed himself in this way in his former remarks which I felt called upon to condemn, instead of asserting that such birds were "of a quiet and tame disposition," my public appearance in your paper would have been avoided.

My friend (I discuss the matter with the most friendly feeling), displays a strong propensity for jumping to extremes, presuming that because I dislike "fan-tails and lowered wings," I must be an advocate of "drooping tails and wings carried half across the stern," and never for a moment considers it possible that I may fancy the stamp of birds belonging to the celebrated breeders of which he takes notice, and whose strains he so justly holds in the highest estimation. These birds he says, "are fit both to fight and to exhibit, whatever form of tail they may present." Now, I venture to assume, that they are neither "fan nor drooping-tailed;" neither do they carry their wings "half across their sterns like Geese;" nor do they cover their thighs therewith, but occupy a medium position in all these respects, and hence we come to the only possible conclusion which must be apparent to all—viz., that the tails and wings have nothing at all to do with the fighting qualifications.

I am next reminded, that "exhibition birds are rather of a different type from real fighting birds in many strains." Supposing this to be granted, it is not necessarily the case, which Mr. Dickens himself admits when he says that those "birds he considers perfection are fit both to fight and to exhibit." I never saw a real cock fight, detesting as I do such brutal practices, but the principal points which I strive to attain in my exhibition birds would, I doubt not, be of good service in the "pit." For example: A good square front; strong, curved, and firmly-set mandible; short, close, hard feathers; and thick muscular thighs of moderate length and well displayed, would be viewed with gratification both by exhibitors and cockers. A cock of this stamp has not the same Hamburg display of tail as the soft-feathered birds, which tends greatly to its advantage, as it is quite natural to suppose a Game fowl should not be encumbered with plumage.

While Mr. Dickens asserts that I made an incorrect statement in hinting that he advocated "drooping wings," he makes a too conspicuous attempt to get the wings put in better position by raising them somewhat above the mire and causing them now only to shield the "upper part" of the thighs; whereas in his former article they were required to "shield the thighs." By another week I trust my friend will have given them another "hitch," and allowed them to spring into their proper place—viz., lying closely pressed against the sides of the body with their extremities meeting immediately under the root of the tail. In any other direction the bird is prevented from displaying that handsome wedge shape which is one of its most characteristic beauties.

Mr. Dickens further remarks that my birds must be "slow," as, "if they had been quick good birds, they would have killed each other in a few minutes;" but Mr. Dickens is somewhat like his strain in this respect—a little too fast, for he does not take time to inquire after the age of the birds before he fixes their doom. I was not aware that cockerels unspurred could do such dreadful execution in so short a time, and fondly hope, with me at least, this will never be the case. Mine are "mere exhibition birds," and all I do to maintain their fighting qualities is to adhere to the careful annual introduction of fresh blood.

With regard to "using a stick or weapon of defence," Mr. Brown is quite qualified to defend this statement, and I doubt not, if it can possibly serve any good end, he will gladly do so. Of course Mr. Dickens's favourite "game birds that are not our exhibition birds in general, but a smaller bird altogether," will have a less telling effect upon that gentleman's hand than Mr. Brown's two-year-old exhibition bird.

Before closing allow me to express my hope that Mr. Dickens is now convinced of the impropriety of advocating in so widely circulated a paper as "our Journal" the introduction of a stamp of fowls to which he would never give a prize in the exhibition pen, the more especially as we have got him to admit the existence of birds "fit both to fight and to exhibit." These are the birds we should attempt to spread over the country, and at the same time use our utmost endeavour to dispel from our midst the "rubbish," which can only bring disgrace on the majestic birds that proudly bear and maintain the name of "Game."—H. GOODALL, *Sion House, Kirkcaldy.*

EXCESS OF EGGS.

I HAVE a two-year-old Rouen Duck that last Sunday laid three eggs before eight o'clock in the morning, on Monday one, on Wednesday two, one of which weighed 6 ozs., and on Friday two more. All the above were properly shelled. I have only two Ducks and a drake, so cannot be mistaken. On the

Sunday there were four eggs. Two years ago I had a Duck of the same breed that laid eggs in the same number of days, never missing during the time.

Should you deem fit to insert the enclosed, you are at liberty to do so.—CHARLES SEDGWICK, *Ryddesden Hall, Keighley.*

[The money for the fowls you sold two years ago can be recovered by suing the purchaser in the County Court.]

HULL AND EAST RIDING POULTRY EXHIBITION.

This was held in the Public Rooms, Jarratt Street, Hull, on the 12th and 13th inst.

In addition to the money prizes, there were three silver cups given by the Society for the best pens of Game: a silver cup, by J. Easton, Esq., for the best pen of Bantams; and a silver cup, given by Mr. W. E. Easton, for the best pen of Pigeons. A sixth silver cup, was given by Thomas Reynoldson, Esq., for the best Lop-eared Rabbit; and a bust of Vesta, with pedestal, in Parian marble, was given by E. J. Davis, Esq., as an extra prize in the Spanish, Dorking, and Cochins-China classes.

The following is the prize list:—

GAME (Black-breasted, or other Reds).—Cup and Third, J. Fletcher; Stoneclough, near Manchester (Black Reds). Second, S. Matthew, Chilton (Brown Reds). Highly Commended, H. M. Julian, Hull (Reds); J. H. Wilson, St. Bees (Black Reds); C. Chaloner, Steeley.

GAME (Any other variety).—Cup, J. Fletcher. Second, W. Boyes, Beverley (Duckwings). Third, H. M. Julian (Duckwings). Highly Commended, H. M. Julian; S. Matthew.

GAME COCK (Any variety).—Cup, H. M. Julian. Second, J. Fletcher. Third, W. H. Wheeler (Black Red). Highly Commended, J. Fletcher; S. Matthew (Black Red); G. E. Smith, Scarborough; R. Woods, Osberton (Black Red). Commended, Church & Houlding, Nantwich (Brown Red); J. Brough, Carlisle; J. Whitfield, Hull.

SPANISH.—First, H. Beldon, Bingley. Second, J. R. Rodbard, Wington, near Bristol. Highly Commended, H. Beldon. Commended, Burch and Boulter, Sheffield; J. Thresh, Bradford.

DORKINGS (Any variety).—First, W. H. Robson, Louth, Lincolnshire (Coloured). Second, Mrs. M. Seamons, Hartwell, Aylesbury. Highly Commended, T. Morris, Uxley; Mrs. E. Hart, Alderwasley, Derby (Coloured); J. Egan, Newark; C. Chaloner.

COCHINS (Cinnamon or Buff).—First, W. A. Taylor, Manchester. Second, T. H. Barker, Hovingham. Highly Commended, H. Savile, Ollerton, Notts; Ganson & Jefferson, Whitehaven; J. Cattell, Birmingham.

COCHINS (Any other variety).—First and Extra, T. Stretch, Ormskirk (Partridge). Second, E. Haworth, Haslingden (White). Highly Commended, Mrs. A. Williamson, Leicester (White); B. S. Lowndes, Stoney Stratford (Partridge); J. K. Rodbard (Partridge); J. A. Taylor, Manchester (Partridge).

BEANHANS (Any colour).—First, Mrs. F. Hunt. Second, E. Leech, Rochdale. Highly Commended, J. K. Fowler, Aylesbury.

HAMBUERS (Golden-spangled).—First, J. S. Senior, Dewsbury. Second, G. Holmes, Driffield. Highly Commended, H. Beldon; H. R. Ashton.

HAMBUERS (Golden-pencilled).—First and Second, J. R. Jessop, Hull. Commended, H. Beldon.

HAMBUERS (Silver-spangled).—First, H. Beldon. Second, J. Walker. Highly Commended, H. Beldon; H. Pickles, jun., Earby, Skipton.

HAMBUERS (Silver-pencilled).—First, H. Beldon. Second, H. Pickles, jun. Commended, C. Haworth.

POLANDS (Any variety).—First, J. S. Senior. Second, Mrs. E. Procter, Hull. Highly Commended, Mrs. E. Procter; G. W. Boothby, Louth, Lincolnshire.

ANY VARIETY, NOT BEFORE MENTIONED.—First, W. H. Tomlinson, Newark (Sultans). Second, Col. S. Wortley, Grove End Road, London (French). Highly Commended, Rev. P. W. Story, Daventry (Nigger Bantams); Mason & Walker (Black Hamburgs). Commended, Mrs. J. E. Cross, Brigg (Crown-Coups); J. K. Fowler (French).

GAME BANTAMS (Any variety).—First Mrs. E. Crawford, Southwell. Second, W. F. Entwistle, Leeds (Black Reds, Game). Highly Commended, W. Parker, Clay Cross; Rev. G. Raynor, Tombridge (Black Reds); L. Biney, Manchester; E. Toder, Little Carlton. Commended, W. Dale, Weston-uper-Mare (Black Reds); R. Smith, Hull; J. Gawan, Beverley. Cock.—First and Cup, J. Fletcher. Second, J. Bamber, Accrington (Black Red). Highly Commended, W. F. Entwistle (Black Red); J. J. Cousins, Alerton (Black Reds); T. Whitaker, Melton Mowbray (Pile); B. Jarvis, Mansfield; W. J. Cope, Larnsey (Black Red).

BANTAMS (Gold or Silver-laced).—First, H. Praycott, Humberstone. Second, T. C. Harrison, Hull. Commended, T. C. Harrison; H. Beldon.

BANTAMS (Black or White).—First, E. Cambridge, Bristol (Black). Highly Commended, J. R. Jessop; W. H. Tomlinson; W. E. Graham. McCrosie; S. and R. Ashton, Maccam. Commended, H. Beldon.

DUCKS (Aylesbury).—First, Mrs. M. Seamons. Second and Highly Commended, J. K. Fowler.

DUCKS (Rouen).—First, J. J. Stett, Rochdale. Second, E. Leech. Commended, H. Dowsett, Tisbury; P. Parlett, Chelmsford.

DUCKS (Any other variety).—First, T. C. Harrison. Second, J. Dixon, Bradford (Bantams).

SELLING CLASS (Any variety).—First, H. Savile (Crown Coups). Second, W. A. Taylor, Aitclough (Cochins). Highly Commended, M. Ferrand, Dalton (Spanish); S. C. Noble, Kendal (Silver-spangled Hamburgs); Lady L. Clauert (Houdans); Bowman & Pearson, Whitehaven (Silver-spangled); H. M. Julian (Game); T. C. Harrison (Ducks). Commended, Ganson & Jefferson (Rouen).

PIGEONS.

CARRIER.—Cock.—First, J. Hawley, Bingley (Black). Second, J. C. Ord, Fimlico, Leeds. Highly Commended, R. H. Artindale, West Derby; R. Fulton, Doughty; E. Tardley, Birmingham. Commended, Dr. Thompson, South Black. Hen.—First, J. Hawley (Black). Second, R. Fulton. Highly Commended, J. Hawley (Dun). Commended, R. Fulton.

POUTER.—*Cock*.—First, W. Harvey, Sheffield. Second, P. H. Jones, Fulham. Highly Commended, R. Fulton; H. Yardley. Commended, R. Fulton; P. H. Jones. *Hen*.—First, W. Harvey. Second, R. Fulton. Commended, J. Hawley (Blue).

TUMBLERS (Almonds).—First, J. Hawley. Second, P. H. Jones. Highly Commended, R. Fulton; F. Key, Beverley. Commended, R. Fulton.

TUMBLERS (Any other variety).—First, J. Hawley. Second, R. Fulton. (Agate Mottled). Highly Commended, R. Fulton (Mottled); H. Yardley; T. Statters, Hull (Kites). Commended, Mrs. J. E. Cross (German Feather-footed).

BARNIS.—First, J. Firth, jun., Dewsbury. Second, J. Hawley (Black). Highly Commended, P. H. Jones. Commended, A. Dove, York; P. H. Jones.

OWLS.—First, J. Fiddling, jun., Rochdale. Second, J. Clark, Thirsk (White African). Highly Commended, A. Dove. Commended, J. Marshall, Driffield.

FAN-TAILS.—First, J. Hawley (White). Second, R. Moll, Hull. Highly Commended, H. Yardley; T. Ellington, Beverley. Commended, T. C. and E. Newbitt, Epworth, near Bawtry.

JACOBIANS.—First, J. Hawley (Red). Second, T. C. & E. Newbitt. Highly Commended, C. Bulpin, Bridgewater.

TURBITS.—First, T. Statters. Second, J. Thackray, Petergate, York. Highly Commended, J. Hawley (Silver); W. Lund, Shipley; P. H. Jones; J. Thackray. Commended, J. T. Lishman, Gillington; R. Paterson, Melrose (Blue); R. Wilson, Thirsk (Blue); C. Bulpin.

DRAGONS.—First, P. H. Jones. Second, H. Yardley. Highly Commended, H. Taylor (White). Commended, H. Yardley; J. Deakin, Sheffield; C. Bulpin.

ANY NEW OR DISTINCT VARIETY.—First, J. T. Lishman (Magpies). Second, R. Moll (Nuns). Highly Commended, J. Hawley (Trumpeters); J. T. Lishman (Swallow); H. Yardley; J. Clark (Swiss). Commended, H. Yardley; Dr. Thompson (Archangels); H. Draycott (German Toys); S. A. Wyllie, Kingston-on-Thames (German Toys).

SELLING CLASS.—First, H. Yardley. Second, E. J. Bell, Whitefriargate, Hull (Mottled Trumpeters). Highly Commended, J. Hawley (Pouters); C. Bulpin. Commended, H. Taylor (White Dragons); J. Firth, jun.; J. Hawley.

RABBITS.

LOP-EARED (taking all properties).—First, Cup, and Second, W. Allison, Sheffield. Highly Commended, A. H. Easton, Hull; W. S. Hornby, York; C. Gravill, Thorne; M. Millington, York. Commended, A. H. Easton; J. R. Jessop; J. Wagstaff, Doncaster; S. Hall.

LOP-EARED (Black and White, Grey and White).—First, M. Millington. Second, A. H. Easton. Highly Commended, R. Keyworth, Hull; C. Gravill. Commended, W. S. Hornby; J. Wagstaff.

LOP-EARED (Yellow and White, or Tortoiseshell).—First, A. H. Easton. Second, C. Gravill. Highly Commended, M. Millington. Commended, W. Allison.

HEAVIEST.—First, J. Taylor. Second, A. H. Easton. Highly Commended, W. Pratt, Birmingham. Commended, W. Neal, York.

PAIR OF ANY OTHER VARIETY.—First, C. Rayson, Manchester (Angora). Second, R. R. Wise, St. Ives (Silver-Grey). Highly Commended, A. H. Easton (Silver-Greys); R. R. Wise (Silver-Greys); J. R. Jessop (Himalaya); C. Rayson (Himalaya). Commended, J. Taylor (White and Gold).

The greatest length of ear was 2½ inches, and the greatest width 4½ inches. The heaviest weighed 14 lbs.

CANARIES.

BELGIAN (Yellow).—First, G. Grant, Beverley. Second, T. C. Harrison. **BELGIAN** (Buff).—First, J. Bexson, Derby. Second, G. Grant.

MULE.—First, W. Campey, Beverley (Goldfinch Mule). Second, J. Bexson (Jonque Goldfinch).

MARKED.—First, J. Bexson (Yellow). Second, J. Gawan.

SELLING CLASS (Any Variety of Small Birds).—First and Second, J. Gawan (Canary and Redcap).

JUDGES.—Mr. Edward Hewitt, Sparkbrook, Birmingham; Mr. H. Adams, Beverley; and Mr. Enoch Hutton, Pudsey, Leeds.

INCUBATORS—RICE AS FOOD FOR POULTRY.

ALTHOUGH a manufacturer of incubators, may I be allowed to say one word in their favour? They possess at least one qualification, a most important one, to which, perhaps, many a breeder has never given a thought—an incubator is always a friend in need. I can speak very forcibly on this point this season, for hardly a chicken I have but owes its life either directly or partially to an incubator. My sitting birds have been mostly Brahma pullets, and have accordingly been in most cases restless or awkward—sat well enough, perhaps, part of their time, or else managed to kill their chickens as they hatched. They also sat on stale eggs one month or six weeks old, the chickens from which are always difficult to get out of the shell. Then my incubator was a friend indeed. It was never restless—it never trod its chickens to death. Let me, then, as a lover of poultry, not as an incubator-maker, draw the attention of all breeders strongly to this point, and also to the fact that, with an incubator working, a hen never need have only half a brood of chickens to run about with her.

Allow me also, with all submission, to state that my experience of rice meal and feeding rice is totally different to the advice I have seen repeated more than once. I find it the most valuable food—the staple, I may say, wherewith to work all other foods. My birds have done admirably on it, and for price there is no comparison between it and barley or oatmeal. —FRED. H. SCHRÖDER, *Rickmansworth*.

EFFECTS OF CHILL UPON UNDEVELOPED BROOD.

On the 24th of May, 1866, I stocked my unicomb hive with an artificial swarm, by driving the bees out of an ordinary straw hive, and then running them with their queen into the observatory hive. The queen was very prolific, and in three weeks had filled almost every unoccupied cell with brood, and young bees were emerging from their cells on the twenty-first day after the introduction of the swarm.

I left home upon the 16th of June, and on my return, only three days afterwards, observed a great number of bees dead on the ground in front of, and also at the entrance of the hive. At first I supposed that the hive had been attacked by strange bees, but on opening the shutters perceived that the bees were dying of starvation. Having removed the hive into the house, as the weather was very inclement, I sprinkled the bees with warm syrup, and eventually about a fourth part of them revived; but the queen with the remainder had succumbed to cold and famine. My first impulse was to destroy the colony, and remove the combs, which were entirely filled with brood, but on further consideration I resolved to wait and see if the bees would attempt to raise a queen, and also what would become of the brood. For some days perfect bees continued to emerge from the cells, but all that came out subsequently were more or less imperfect in one or both of their wings; many, indeed, looked exactly as if their wings had been cut off quite close to their bodies. When a few days old, these bees as usual came out to take an airing, and fell to the ground, so that the hive was for some time constantly surrounded with these unfortunates crawling about in all directions.

The bees did not attempt to raise a queen, so in about a week I presented them with a young queen as the legitimate successor to the vacant throne. Although the bees had been so long without a queen, she was not accepted without a good deal of harsh treatment, and I had to release her several times from the clutches of her future subjects. As the surviving bees barely occupied one-half of the hive, a large quantity of brood was entirely neglected. This did not, however, produce any symptoms of foul brood. The dead brood was for the most part dragged out of the cells sooner or later; but when the grubs were small, a spot of discoloration was visible at the bottom of new cells. Eggs subsequently deposited in these cells were hatched in due course, and no disease has since made its appearance in the colony.—J. E. B.

BEE MANAGEMENT.

"CAN you inform me if this is the direct way to a certain house?" inquired I of what appeared to be rather an eccentric character, one day when paying a visit to a certain bee-keeping friend. "Did you pass a big white house and a large black dog lying in front? If so, you will come to the house as soon as you pass over the bridge; but if you did not pass it you will have to turn back." This was the rejoinder. The same thing applies to many subjects, but to bees in particular, as, to come to the proper mark, we must take care to pass the proper points that may be in the way to whatever we aim at.

Supposing, then, that apiarists have managed their bees with every care and caution from September up to this date, having been careful at that time to have them well fed, thoroughly defended from the inclemency of the weather, internal moisture, and vermin—if all this has been done we may presume them to be on the fair road to success, and that they will not require to turn back, or to wait another season, but will be sure to gain the mark. I will, therefore, endeavour to give a few instructions relating to the management of bees from this time forward, so that the most may be made of them.

Presuming, then, that the stocks are in fair condition, that they are well aired, the floor board cleaned, and pollen-carrying commenced, the apiarist ought to attend to them, and by judicious feeding to have them in a forward state at the end of April or the beginning of May, or, according to circumstances, it may be the end of May or beginning of June; but at whatever time they become crowded, the apiarist ought to mark those intended for swarming and those for sterilizing, pushing forward the former (every fourth hive should be kept for this purpose), and giving additional room to the latter, so that nothing may impede their progress, assisting them at the same time with whatever empty combs he may have in his possession. By pursuing this course the apiarist will seldom fail to have an abundance of honey even in a year like 1867, when a

neighbour of mine took no less than 42 lbs. of first-class surplus honeycomb from each hive, simply by working up to these directions.

To return to the subject of swarming. I will endeavour to point out the cause and effect, describing, as I proceed, the different phases that take place, and how a swarming hive may in some years be the most profitable. As I have already mentioned, every fourth hive ought to be allowed to swarm, or, which is better, be kept for making artificial swarms. The first signs of swarming are a number of the older bees becoming less active, the cause of which is that every cell in the hive is occupied. The queen, finding no place in which to deposit her eggs, becomes restless, traversing the hive in an uneasy manner, and not unfrequently rushing towards the outside combs, which being disliked by the bees, she is commonly surrounded by their ceasing to open up a clear way for her passage, but rather forming, as it were, a kind of encasement; a general commotion arises as the heat increases, and often the swarm departs, almost the whole of the bees leaving, many hundreds of young ones falling on the ground, not able to follow, and at this time not a single queen cell has been commenced. These are the swarms that frequently go astray, issuing without the slightest warning, and leaving the apianian to deplore their loss, the only means by which he could have saved them being to take them artificially. There is another phase which sometimes lasts so long that it causes the bee-keeper to lose all patience—at least it often makes him lose all honey by their idleness.

When the cells have become fully charged the queen paces to and fro until she is encased and permitted to range through part of the hive only, when, being kept apart from many of the young bees, they immediately commence queen cells; for be it understood that young bees are those which commonly perform that duty, the old bees taking less interest in it than the young ones. Whilst this is going on the bees get divided, as it were, the old queen attempting the destruction of her rivals while yet in embryo, and in this she often succeeds; but when bees once commence raising queens they are not easily thwarted, although some may be destroyed. This rather increases their vigour and determination, and as the heat increases their activity the commotion commences, the queen straining every nerve to destroy her successors, and the young bees pertinaciously resisting until the old queen, once so reluctant, becomes but too glad to resign her own will to that of her people, and woe betide the haughty sovereign who will not do this.

The swarm having now issued, and being safely hived among combs of the previous year—which the apianian will always have by him if he attends to my instructions—if early, and it happens to be a protracted honey season, it will, with its after swarms, produce more honey and combs for future use than if swarming had not been allowed. It must, however, be borne in mind that, as a rule, unless in protracted seasons, the storified hive is the profitable one for the current year; but to insure success and to have in readiness a large quantity of empty combs in case of foul brood, or to use for nading or the exchanging of full for empty combs when a sudden honey harvest presents itself, it is essential that a fourth of the stocks should be allowed to swarm annually.

To insure success with hives on the storified principle they must be attended to in time ere they have settled on swarming, giving room below if honey is yet scarce, but if plentiful the super may be put on. Much attention is, however, required, as giving room does not always prevent swarming, for bees will frequently swarm out of a large hive only partially filled, the same as from a small one. The cause of this is that it never was designed that a queen should lay all her eggs in one season, or that she should lay continually. Nature demands a rest, and this happens earlier with some queens than with others. So, when a queen relaxes laying whilst the hive is still active, the bees feel indifferent towards her, young queens are brought forward, and the old queen is commonly killed by the young ones, or meets an untimely end by her own subjects; thus many a young and fertile queen is lost. The only way to prevent it is to remove her, if a valuable one, ere they have done with her; and a stock under these circumstances, when the hive is well filled with young bees, will make more honey, which, moreover, is sure to be free from brood while the young queens are coming forward, than if the old sovereign were still regnant.

Small nuclei ought to be formed in case of any accident happening to the old stock or the old queen and every cell but

one cut out, so as to prevent after-swarms issuing, as they will undoubtedly do if this precaution be not taken. I have had swarms issuing from stocks after being divided into three. It will be easily seen from the foregoing under what circumstances piping takes place before a swarm has issued, and how to prevent swarms issuing, and that swarming at all is a natural act arising from different circumstances through the instinct of the bees.

I have thus given a brief outline of the management of bees, pointing out the appearances at swarming, and its phases as learned by long and patient watchfulness and by observation of the nature of the bee. I have not worked on the experiments of others, but started on a basis of my own, observing patiently for more than a quarter of a century, and carefully watching every aberration that took place; nor were my observations confined to what may be termed the dingy houses of olden times—viz., straw hives, but the modern hive with many of its improvements.

To insure success with bees, everything that will economise life should be resorted to, not, if possible, allowing a single bee to perish. Using nice dry mats made of straw for their floors in winter would save many a bee. Many bee-keepers about here appraise each bee in February and March at a halfpenny, and the following anecdote will show what value an old man put on his bees. He had a favourite cat, and one day a bee happened to be on the window, when pussy made a spring and broke the window. "Confound it," said the old man, "there's a guinea bee killed." Attending carefully to bees during autumn and winter is the surest way to success, at least it has been proved to be so by—A LANARKSHIRE BEE-KEEPER.

P.S.—I have in my possession frames which were used by me many years before the famed Woodbury hive made its appearance, and which were subjected to many an alteration of form for the sake of observation, although those commonly used by me were frames left open below, having the top bar projecting over the hive, and having the two end pieces only. This being the shape of the frames, the outside case had one end moveable, sliding on two dovetails, by which means the hive could be enlarged or contracted at will, being partly on the lateral system, but never allowing it to be larger than a common hive, as I always considered the lateral or collateral system an utter abomination, and in direct opposition to the nature of the bees.

OUR LETTER BOX.

FOWLS DYING WITHOUT APPARENT CAUSE (C. E.).—It would have rendered it easier for us to have given an answer if you had told us the breed of the fowls that have died. You say Spanish and Brahmas have escaped. If those you have lost were La Fleche there is no marvel; they are healthy in the morning, dead at night. Creve Coeur are sometimes sick, but they seldom die. There is no fault to find with the feeding; but we are always averse to feeding with bad food. There is no economy in it, and it should be portioned rather as to weight than bulk. Lettuce is good for them, cabbage is little better than nothing. Feed on your kitchen scraps, with your best barley. Have they a grass run? If they have not, it is probable they die from internal fat. We never tried lobster as poultry food, but we should not hesitate to do so. The barley is perfectly clean, and in the absence of other proof we should be disposed to attribute the cause of death to pecking the fresh paint. All birds are fond of doing so. If they have no grass run cut some heavy sods of growing grass with plenty of mould, and let them have it every day.

GAME FOWLS WITH DISEASED LIVERS.—"For some time past several of my Game hens have died, and on opening them their livers have been invariably found to be full of small stones, which no doubt caused their death. They are Duckwing Greys. Can any one explain the origin of their disease, and suggest a remedy for it?"—E. O.

PARROT SUBJECT TO FITS (Parrot).—You have not stated what kind of Parrot you have. If it be a Grey one, the only reason we can assign for its having fits is that it has not sufficient moist food, and the seed is not nourishing enough. It should have scalded bread mixed with hempseed, fresh every day; water to drink should also be given, and occasionally fruit of any description. Equal quantities of hempseed and canary seed should be placed in the feeding box. Should the Parrot continue to have the fits, mix one-third of rum to two-thirds of water for it to drink and give it a piece of bread or biscuit soaked in this mixture while warm and occasionally also in warm coffee.

MAGGOT IN CORKWORK (R. Palmer).—We know of no application that will check its ravages, unless you can soak the model in spirit of turpentine.

POULTRY MARKET.—MAY 13th.

We have still but a scanty supply of goods at market, and prices are high. We may shortly look for a better supply of some of our spring poultry.

From observations taken near London during the last forty-one years, the average day temperature of the week is 66.9°; and its night temperature 43.8°. The greatest heat was 89°, on the 22nd, 1847; and the lowest cold 20°, on the 23rd and 25th, 1863; and 23rd, 1861. The greatest fall of rain was 0.64 inch.

A TRIO OF SIMPLICITIES.

QUAL to the blue Lobelia as an early spring decorative plant for the greenhouse or conservatory is the old but deservedly popular annual, *NEMOPHILA INSIGNIS*, and yet how seldom we see its decorative capabilities conducted in a manner worthy of the simple beauty of the plant itself when anything like justice is done it in respect to ordinary cultural attention. Wiry, drawn, and sickly, it may commonly be seen skulking in an out-of-the-way place or behind the commissariat department of a more aristocratic neighbour, as if ashamed that its plebeian order should be seen, or its miserable habiliments be looked on with contempt. Far less commonly is it to be seen clothed in chaste and flowing drapery, neat, trim, and in blooming health, standing boldly forward, challenging inspection, and reciprocating the smiles of appreciation which under these circumstances will be accorded to its native grace. I will not for a moment call into question the laudable ambition which animates the breasts of practical gardeners and horticulturists of the present day. The triumphs and successes which have been attained are a standing monument to their skill, energy, and industry. But has not this spirit of emulation—honest and praiseworthy all must allow it to be—had a tendency to direct attention almost exclusively to the higher regions of floral art? while subjects of less importance have become in a measure forgotten, though they are nevertheless valuable adjuncts, not merely on account of their intrinsic beauty, but in many instances as forming the connecting link between the dreariness of winter and the profuse beauties of summer.

The picture I have drawn of the *Nemophila* is not an ideal one. For the past two months it has occupied a prominent place in the house which it is my duty and pleasure to keep constantly gay and bright with flowers in variety. Associated with Azaleas, Camellias, Roses, Pelargoniums, Calceolarias, Cinerarias, &c., it has given a diversity of form, as well as of colour, which has been greatly admired. Its light airy appearance, blending in a pleasing manner with the somewhat massive and stiff plants associated with it, has added much to the beauty and effect of the collection as a whole. For a continuous fringe or edging to a mixed collection of plants in flower, nothing can well be more elegant and give a more finished appearance than a line of the blue and white varieties in mixture. As a plant for a hanging basket it is extremely suitable, and has a charming effect. Another and important advantage connected with it is, that it is within the reach of all who have a sixpence and a plot of ground to spare in September.

I sow in the first week of that month in an open place in drills a foot apart, choosing a firm and rather poor piece of ground in order to secure a somewhat slow and sturdy growth. When well above ground the plants are thinned out, leaving them singly 2 or 3 inches apart. Every individual plant then becomes well hardened by a constant circulation of air about all its parts and is in a state to

resist the effects of any ordinary winter. If left in the rows unthinned the centres of the plants will become drawn and tender, and the whole of the sowing will be sure to be killed by frost.

The plants which are intended for window decoration are potted in 6-inch pots, and plunged in ashes in a cold frame, giving them all the sun and air possible, and closing the sashes only in extremely wet and boisterous weather. Close confinement and tender nursing are ruinous to them. In January they are transferred to a very light and airy shelf in the greenhouse. In February they will commence to open their flowers, and during the latter part of the month and throughout March and April they will continue masses of chaste beauty, falling over the pots in folds and tresses of the most delicate colour and texture. To keep them, however, in health and in continuous bloom for this length of time attention must be paid to watering. If once allowed to become very dry the foliage turns yellow and sickly, and the beauty of the plants is gone. They are quite worthy of an occasional dose of liquid manure, which improves the colour of the flowers, and prolongs their season very considerably.

The plants which are not required for in-door effect are left in the seed bed, and transplanted to the flower garden in March. If planted on the massing system for an early display, they should be packed in the beds as closely as possible. A bed of them here (April 29th), in a north-west aspect in lat. 53° N. is covered with bloom, presents a cheerful appearance, and is much admired. Plants raised from seed sown in spring are poor in comparison to those sown in the autumn. They do not even approach them in size, colour, or duration.

Much of that which I have stated with regard to the *Nemophila* will apply to my next simplicity—*Collinsia Verna*. This is distinct from all others of the family. It is more hardy than they, and possesses the important property of flowering much earlier. It is worthy of universal cultivation. From the humble plot of the artisan to the elaborate parterres of ducal gardens, its vernal beauty entitles it to a place where it will hold its own amongst the limited floral surroundings which exist at the season of its blooming. A few well-grown potfuls in a conservatory during March are sure to attract attention.

The cultural attention may be precisely the same as for the *Nemophila*, except as to sowing. Considerable moisture, constant and uniform, is necessary to insure germination. The ground at the season of sowing—the end of August—cannot be depended on to afford these essentials. The plan I find the best is to sow in pots, which are kept standing in saucers of water. Requisite moisture is thus supplied by capillary attraction. The pots are placed in a cold frame, and shaded until the seedlings appear. When these are fairly up they must be pricked out in the open garden, or in pots if a few are desired to bloom in-doors. Their great enemies are slugs. From the persistency of their attacks, and their determination to break through the ordinary barriers of soot, lime, guano, &c., this plant must be a dainty dish to them. My sheet-anchor is to saturate some sand with gas tar, and lay a band of it

round the bed in which they are planted, pouring from time to time a little fresh tar on the sawdust. The slugs will not face this.

The plant which completes my trio is the SINGLE ANEMONE. Some may not consider the harmony good here, as this plant is different in character from the foregoing. To this I will not object, but when the flowers are seen in large masses, their brilliant and diversified colours burnished by the early sun, and their glittering forms dancing in the gentle breeze, which is drinking the morning dews from their gorgeous cups, they are a sight dazzling to look upon. The foliage, too, how elegant it is! a garb, indeed, which many a Fern might be proud to wear. And what is to prevent this plant from becoming a staple object of beauty in every garden? Simply nothing but plenty of seed, which it yields in abundance, and a patch of ground to grow it on. I am perfectly aware that to produce individual flowers of high excellence some preparation is necessary. I am not now looking at it as a florists' flower, but in its adaptability for general effect, and the simplest mode of managing it. This, then, after a considerable degree of experience, I find to be by sowing a bed of seed annually early in May, or as soon as ripe. Sow in drills about 9 inches apart, well watering them previous to putting in the seed, and keep the ground moist and shaded until the seedlings appear. Thin them out when large enough to handle. Give them generous summer treatment by frequently stirring the ground, and occasionally water them with weak liquid manure. If well attended to in all these respects, and the weather is mild, they will commence flowering the same autumn.

When the beds are cleared of their summer occupants lift the Anemones in clumps, and plant them in the beds as thickly as it is possible to crowd them in. In March, April, and May they will give a return which will amply compensate for the time and trouble expended in their preparation. The roots can of course be taken up and planted again in the autumn, but the summer beds are seldom cleared in time for them to flower sufficiently early by this mode, and if planted in reserve I have not found them remove so well, and make such certain and satisfactory progress as seedlings. A gentleman, a former employer, on April 20th writes me: "The Anemones, as usual, are truly splendid, the attraction and admiration of the neighbourhood." This, I am sure, is only doing them the simple justice which their beauty demands.—J. W.

THE MEANS FOR PREVENTING DAMPNESS ON GRAPES.

"Why does my neighbour make his Grapes hang till the end of January, while mine are mouldy in December?" To some nothing seems so mysterious in the cultivation of the Grape as this difference, and therefore I venture to offer a few remarks on the subject.

It must be owned, that if Grapes are more valuable at one time than another, that time is the Christmas holidays, and it is provoking to find that the beautiful bunches of Grapes, which in November promised to decorate many a Christmas dessert, are shrivelling and blue with mouldiness when they are really wanted. That some persons do not experience an inconvenience of this kind is well known, and their neighbours wonder at a success which no pains of their own will secure, and which have only one fault, that of misdirection. Grapes are ripened well and then protected with a care which defeats itself. The vinery is shut up closely to keep out damp, fires are lighted to complete the ripening, and greenhouse plants are brought in to participate in the shelter. The first two are the provisions made for safety; they are in reality the conditions of destruction.

When Grapes are perfectly well ripened they have within themselves the elements of preservation in a variable degree. Fleshy sweet berries, such as Muscats, have the greatest tendency to remain unchanged; juicy, sub-acid sorts, like the Black Hamburgh and Sweetwaters, on the contrary have the least. The difference appears to depend upon the proportion of sugar they respectively form; the sweetest Grape keeps best, the most acid worst. In either case dampness promotes decay, dryness arrests it. There is no doubt that by a very skilful management of warm dry air, raisins might be prepared from Sweet-water Grapes as they now are from Muscats; but in a country like England, with the atmosphere always containing so much water suspended in the form of invisible vapour, some precautions must be taken to deprive the air of its moisture as far

as practicable. The question is, What are those precautions? Merely to shut up a vinery is to do nothing, or worse than nothing. Air is not the less damp when enclosed between brick walls and a glass roof. As it was when shut up so it remains, changed by nothing except the addition of more moisture by indraught through the door, roof, and ventilators. Plants brought in for shelter contribute nothing to dryness; on the contrary, the perspiration of their leaves very sensibly diminishes it; moreover, during the cold nights of December the aqueous vapour of the house itself—a most formidable enemy, condenses on the glass roof, and drips upon the bunches; then the footstalks of the berries soon become brown and dead, moulds—funguses—invade the bunches, and corruption spreads among them.

What ought to be done is this. The Grapes being ripe, the inside of the vinery should be made as dry as possible by the constant admission of dry warm air whenever the mid-day is warm and sunny, and it should be still further dried in damp weather by slightly heating the flues or hot-water pipes. It is not a bad plan, indeed, to open all the ventilators for a few days, a brisk heat being maintained at the same time. In this manner the floors, walls, and other objects will be sufficiently deprived of their moisture by the rapid passage of air in consequence of the inequality of temperature between the interior and exterior of the house. At no time under any pretence ought water to be admitted. Good gardeners know this, but amateurs do not. In Spain, where the finest dried Grapes in the world are prepared, it is found by experience, that if only a little dew falls on the Grapes while drying, although they are sweet fleshy Muscats, the raisins are apt to spoil when packed in boxes. Dryness of the air and as much ventilation as it is possible to give, are the conditions to be secured if ripe Grapes are to be kept long during the winter.

If, however, the roofs of the vineries are in a bad condition, always letting in drip whenever there is a little wet outside, it is useless trying to thoroughly counteract the dampness inside, but such a query as I began my subject with, would not be asked by any sensible person whose houses were in this state. A friend who manages one of the now leading fruit-growing establishments in the county of Hants, although himself a most successful Grape-grower, found a difficulty on entering into his new situation four or five years ago, to add to the table requisites on Christmas-day a bunch of Grapes worth eating, yet he had 212 feet run of vinery. Defects in this range, which were the cause of the destruction of so much fruit, were soon pointed out. No Grapes could be better ripened; but dampness in the vineries was the evil, and this could not be remedied, for they were pronounced to be badly ventilated and badly glazed, and, perhaps, worn out as well. Be this as it may, this range came down, and has been replaced by a new one thoroughly waterproof, properly ventilated, and in every respect worthy of its name, and although this is the first year the Vines have fruited under their new roof, the change already has effected the object aimed at, for not only was the table ornamented by Grapes at Christmas, but for three months afterwards.

Something more may be done. If Grapes may be ruined by moisture falling on their surface, their preservation may be rendered more difficult by the introduction of superfluous moisture into their interior. We must not imagine that Vines are incapable of attracting dampness from the soil when Grapes are ripe. On the contrary, so long as Grapes are alive—that is to say, so long as their stalks are green, they imbibe sap from the branches, the branches replace their loss by sucking the stem, and the stem replenishes itself from the watery matter which the roots collect out of the soil. The only way to mitigate this evil is to keep the borders also dry. When a vinery is surrounded by hard gravel walks under which the Vine roots lie, the casing of gravel, half-baked during the autumn, keeps off water for a month or two till the gravel is loosened by a thaw, and by that time, in this country, Grapes generally cease to be much wanted. When, as is most common, Vine borders consist of soft naked soil, they soon become filled with moisture if exposed to the weather. At the same time the temperature of the soil has not fallen low enough to render the roots absolutely torpid. Last December the ordinary soil of a garden stood, at 2 feet below its surface, at 48°, near London, and in a warm Vine border must have been 50°, which is about the ground temperature at which the Vine commences its spring growth in this country. Under such circumstances roots in full action will absorb water with some force, and this must indirectly tell upon Grapes and diminish

the chances of making them keep. The obvious remedy is to keep the Vine border also dry.

There are various modes of effecting this object. The surface of the Vine border may be permanently concreted in a manner that has before been suggested by some persons, or it may be covered by a wooden roof as others have proposed. The simplest and cheapest contrivance is that used at Dangstein, the seat of Mr. and Lady Dorothy Nevill. There Peach trees are trained to a short south-west wall, to which is affixed a framework for lights to protect the trees from late spring frosts, and the fruit from heavy rains when it is approaching maturity. To the corresponding wall on the opposite side of the garden are trained Apricot trees, which are also provided with a casing for the same purpose. Now, these lights are doubly useful, because by the time, or very soon after, the trees begin to require an increase of exposure to the sun and atmosphere to ripen their wood, the Vine border requires shelter from the autumnal rains. A framework for the lights is roughly knocked together and placed over the Vine border, then the lights which have been taken from the Peach and Apricot trees, and which are as long as the Vine border is wide, serve to cover the whole in, and thus the border is effectually guarded from rain and very cold weather. Those who may feel inclined to adopt this plan can, according to their own fancy, please themselves whether they remove the covering in fine weather. If, however, it be thought desirable to do so, a little extra attention will be needed in preparing the covering so as to render it light and portable. Of course, these covers are not intended merely for autumn service, they also secure the borders from the bad effects of cold rain, melted snow, or frost when the Vines are in growth in the spring, and should be provided wherever fine Grapes are wanted.—GEORGE NEWLTON.

FRUITING THE ROSE APPLE.

I SEE in your Number of May 7th, that Mr. Carr, gardener to P. L. Hinds, Esq., exhibited some ripe fruit of *Eugenia jambos*, the Rose Apple, and he is stated to be the first that fruited it in this country. Instead of such being the case, I must have been the first, for I fruited it two years ago in the stove at Hooley, which was then filled with tropical fruits, and I have now young plants 3 feet high raised from the seeds.—J. C. MUNDELL, Gardener to J. C. Pickersgill-Cunliffe, Esq., Hooley Hall, Coudon.

DACTYLIS GLOMERATA VARIEGATA.

As there seems to be much difference of opinion respecting this plant, and as some writers have spoken of it as being either new or not well known, I may state that we have had it at Linton Park since 1857, and I believe before that time. In that year I had edgings of it which withstood the winter; but so many of the plants died off in the following spring that I did not plant it so extensively that season, and leaving it in the ground another year, most of the plants perished, as well as some that were kept in pots—indeed I may say I lost it wholly, but obtained it again, and with a like result. This induced me to believe that the plant was an annual, as only on the other side of the fence the green form is one of our most common Grasses; yet I hardly think this the case, and having since obtained the plant more than once from other sources, and observed a similar unsatisfactory dying-off, not in the case of a hard winter only, but with plants in the greenhouse, I am anxious to know if others have experienced similar results.

Two Grasses of a greyish hue, *Stipa glauca* and a *Festuca* (I believe also *glauca*), thrive very well, and nothing can exceed the luxuriance of the old Ribbon Grass; but, on the other hand, the variegated *Poa* spoken of indifferently by some seems likely to follow in the same way as this *Dactylis*. It has not manifested any signs of becoming green, but is liable to die off like the *Dactylis*. Perhaps some one who has been successful with the latter will report his practice; for my own part, I expected that a hardy plant, as it might be supposed to be, would require no more attention than other perennials, and consequently left much of it to its fate. Some plants, however, were retained in pots and treated as greenhouse plants with no better result. I believe that, like the *Iresine* and some other plants, it does better in the north than near London, and I hope that either Mr. Thomson or Mr. Wills will tell us more about it. I believe that it originated in the county in which the latter lately resided, as I recollect seeing it in a very

luxuriant condition in a garden near Ormskirk in 1856 or 1857, and I suppose its good and bad qualities must be well known there by this time.—J. ROBSON.

ROYAL HORTICULTURAL SOCIETY.—MAY 19TH.

FRUIT COMMITTEE.—Mr. Edmonds in the chair. A prize was offered for the best three dishes of Strawberries, for which there was only one exhibition, consisting of Oscar, Sir Harry, and Sir Charles Napier. Sir Harry and Oscar were large and of fine flavour, while Sir Charles Napier was rather deficient in the latter respect. The first prize was awarded Mr. Barnwell, gardener to John Fleming, Esq., of Kilkerran, Maybole, N.B. A first prize was awarded to Mr. Mills, gardener to Lord Carrington, Wycombe Abbey, for a dish of very fine Elton Cherries. He also exhibited an equally handsome dish of Black Tartarian or Circassian. Mr. Tegg, gardener to the Duke of Newcastle, at Clumber, obtained first prizes for excellent dishes of Royal George Peaches and Brugnion Nectarines; the fruit was very fine, and the Nectarines especially were delicious in flavour. Mr. W. Roberts, gardener to Lord Cranworth, Holwood, Bromley, sent a small, green, oval Melon, which, however, was very deficient in flavour. Mr. B. S. Williams sent fruit of a new hybrid Melon, which was grown in a small pot on the back shelf of ainery. It is said to be twelve to fourteen days earlier than any other known kind, a vigorous grower, and free setter. The flavour was good, but the fruit was not sufficiently ripened. Messrs. Harrison & Sons, Leicester, sent a seedling Apple, named Annie Elizabeth, raised from Bess Pool. It is a large ovate yellow fruit, with a solid, firm flesh, remarkable at this late season, but the flavour was rather passed. Mr. Lomas, of the Willows, Tooting, sent two handsome Cucumbers of Rollisson's Telegraph, which, however, had been kept too long, and were rather pale in colour.

FLORAL COMMITTEE.—Another very successful meeting was held this day. The removal of the shutters of the Council room and extending the tables for exhibiting the plants was a very great improvement, especially on so hot a day. There were a great many exhibitors.

Mr. Bracher, Wincanton, sent cut specimens of Zonal Pelargonium *Comte de Moltke*; also four seedling Pansies, one named Welbeck Black was the darkest-coloured Pansy yet seen; it was most intensely black, without the least shade of purple. The three others—viz., Purple Prince, Black Diamond, and Velvet Cushion, were all very dark flowers. Mr. D. Scarfe, gardener to T. Ronaldson, Esq., exhibited a seedling Pelargonium of the large-flowering section, with very crumpled dark red flowers. Messrs. Rollisson & Sons sent a large collection of plants, which was awarded a special certificate. Among them were *Gymnogramma chrysophylla cristata*, *Bignonia argyrea violacea*, *Pandanus* sp., and several other interesting specimens.

Mr. Wimsatt, Chelsea, exhibited plants of *Coleus Marshalli*, *C. Telfordii*, and *C. Murrayi*; the latter had lost its character from having been too much forced, it will be sent again, and will then, doubtless, receive a certificate. Mr. Wimsatt also exhibited several Zonal Pelargoniums of the Gold and Bronze section—viz., Empress Eugénie, Admiration, The Sultan, Viceroy, Little Golden Christine, and Little Golden Spread Eagle; the plants were small, and the Committee deferred making awards to any Zonal Pelargonium till the special show of these plants, which is fixed for the 16th of June, when a better opportunity for comparison will be offered. The special attraction in this collection of plants was the hybrid Ivy-leaved Pelargoniums, and after sixteen years' perseverance Mr. Wills has thus succeeded in producing a new race of flowers. The varieties not being named could receive no award, but they will be sent again and will then be dealt with. A special certificate was awarded the collection. Mr. North sent a golden-leaved Pansy, which looked as if suffering from disease. Mr. Salter, Hammersmith, exhibited a large collection of most beautiful *Pyrethrums*, the flowers were hardly in perfection. A special certificate was awarded them. Mr. Fry, Manor Nursery, sent a seedling *Verbena*, Dr. Livingstone, a very good scarlet flower with a compact truss, very like *Firefly*.

Mr. Tillery sent a plant of a Variegated Zonal Pelargonium, a sport from Imperial Crimson, of dwarf habit; it may be useful for edgings, but the plant was not in condition. Mr. Turner, Slough, exhibited several seedling Pelargoniums. Tronbador, of a soft salmon rosy tint with a white centre, a remarkably fine flower, received a first-class certificate. Fancy Pelargonium Fanny Gair, East Lynne, a very lively flower, Princess Teck, and Leonard, were each awarded a first-class certificate. Mr. Turner also sent several seedling Variegated Zonal Pelargoniums, some of them of great promise, particularly *Mademoiselle Nilsson* and Mrs. Hugh Burners, these will receive their awards on the special show day. A special certificate was awarded this interesting collection. Mr. Williams sent a seedling white-flowering Pelargonium, useful for bouquets, also *Arachanthus muscifer*, a very curious white Orchid, which received a first-class certificate, and many other plants, among them several Orchids. A special certificate was given for the collection. Messrs. Downie, Laird, and Laing sent four fine specimens of their Golden Bronze Zonal Pelargoniums, and Mr. Tanton, Epsom, seedling *Gloxynius*, too rough and coarse. Paul Jones, a pale lavender, was the best among them. Messrs. F. & A. Smith, Dulwich, contributed a large collection of plants; among them were *Tropaeolum* Mrs. Tredwell, Variegated Zonal Pelargoniums, and seedling Azaleas. Of the last, Rose of

Surrey is a promising flower, but the plant was too small to judge of its merits. Goliath, a large-flowering sort, is very showy, but rough in outline. A special certificate was awarded the collection.

Mr. H. Shrubsole, gardener to the Rev. C. Oxenden, Barham, Kent, sent a seedling Lobelia, called Oxendenii, having small pale blue flowers, not better than many other dwarf seedling varieties; also a small plant of Silver Variegated Zonal Pelargonium, Bride of Barham. Mr. T. Ware, Tottenham, sent a large pale salmon-coloured clove Carnation, of which the petals were so numerous and confused, that, beyond its powerful and agreeable scent it has no particular merit. Messrs. Lee, Hammersmith, exhibited *Asplenium trichomanes* Harrovii, and an Oak, named *Quercus concordia*, with pale yellow foliage; it was requested that the latter should be sent again later in the season. Mr. W. Paul sent cut specimens of *Silene pendula* and *S. pendula pulcherrima*, the *Silene pendula ruberrima* of continental nurseries. Mr. Paul also sent several Variegated Zonal Pelargoniums and a small cut-leaved Pelargonium Little Gem, with small pale rose-coloured flowers.

Mr. James Dobson, Isleworth, exhibited two or three dozen of Pelargonium Magnet; it was awarded a first-class certificate as a useful decorative market plant. It is very free-flowering and of compact habit, and has dark crimson and black flowers. Mr. Watson also sent a small collection of his Variegated Zonal Pelargoniums. Mr. Green, gardener to W. W. Saunders, Esq., brought fine specimens of *Sehizanthus pinnatus splendens*, a very ornamental annual; a first-class certificate was awarded it. In the collection brought by Mr. Green there was a small white Orchid, name and genus unknown; this was one of the gems of the exhibition; also, *Orchis fusca*, the continental variety, and a collection of alpine plants. A special certificate was awarded the collection. Mr. Bragg, Slough, received a special certificate for a collection of Pansies.

SCIENTIFIC COMMITTEE.—Dr. T. Thomson, F.R.S., in the chair. In connection with the spot in Orchids which was discussed at last Meeting, and which is still under the consideration of a sub-committee, Dr. Welwitsch exhibited a number of specimens of leaves of tropical plants, all more or less affected with a spot, which Mr. Berkeley pronounced in every instance to be the result of fungoid action, and not at all similar to that which produces spot in Orchids.

Mr. Berkeley exhibited specimens of the larva of *Coleophora hemeorbiella*, which attacks the leaves of the Pear and the Cherry, not as is usually the case by eating away the whole substance, but by attaching themselves by their discoid suctorial mouth, and extracting the sap from the parenchyma for some distance round the point of attack, which, when they have exhausted, they leave, and commence an attack in another part of the leaf, leaving a small hole similar to a leech bite. Finally they enclose themselves in the leaf, which is rolled up into the form of a tiny cigarette.

Mr. Berkeley then read a long letter from M. De Candolle on Botanical Nomenclature, which gave rise to an interesting conversation on the subject, in which the difficulties to be encountered in dealing with hybrids and cross-breeds was principally discussed. Dr. Hogg considered that the first thing to be ascertained is the point in the pedigree of plants where botanists will consider their work to have ceased, and that of the horticulturist to have begun; because it is quite evident that when a genus or species of plants is so far broken up that the numerous progeny cease to be distinguished by characters which botanists acknowledge to be essential to a correct botanical distinction, then they must be individualised by such fancy names as the florists have been in the habit of applying to them. And the next consideration would be how the system of nomenclature which may be decided upon is to be applied in practice. A sub-Committee, consisting of Dr. Thomson, Dr. Hogg, and Mr. Moore, was appointed to investigate the subject and report to next meeting.

Dr. Welwitsch threw out a valuable hint to horticulturists in regard to the cultivation of some of the most beautiful species of Loranthaceae, many of which can be cultivated on the Fig and the Orange.

GENERAL MEETING.—J. Russell Reeves, Esq., F.R.S., in the chair. After a list of donations had been read, and the election of ten new Fellows, the Rev. Joshua Dix announced the awards of the Floral Committee, and Dr. Hogg those of the Fruit Committee.

The Rev. M. J. Berkeley then commenced his observations by remarking that at the last meeting he had called attention to the "breaking" of some Tulips, which he had grown in his own garden, and said that he had since had confirmation of the view which he then held—namely, that as "breeders" they had broken in consequence of being planted late—in January instead of in November, as they had been in previous years. Every one knew how difficult it was to break breeder Tulips—indeed, it sometimes took twenty years to do so, and the cause of breaking was a mystery. To induce breaking, recourse was had to change of soil, to change of locality, and to various composts, among which various nostrums had been recommended, particularly smoky dust. Sometimes, also, crossing the flowers had been practised to bring about that result, but the cause remained a problem still unsolved. A curious point with regard to his seedling Tulips was that there was a dark brown spot at the base of each petal, and that had vanished in the breaking, giving place to a brilliant scarlet feather, which he had ascribed to the yellow shining through the red. On examining the petals microscopically he had found that the coloured cells were superficial, in fact, cuticular, and that between two layers of

these there were intermediate cells, either entirely colourless or yellow which latter produced the brilliant scarlet. The next subject to which he had to allude was canker, which all were aware is very destructive to fruit trees. In his own garden a very peculiar case had occurred on a Keswick Codlin Apple tree, a portion of which he produced to the Meeting. Swellings had formed at every division of the tree, and these swellings were covered with adventitious buds, and he produced specimens of *Rosa arvensis* and an Elm similarly affected, the whole tree in the latter case being covered with adventitious buds, which acted most injuriously.

Mr. Berkeley next read a letter from the Rev. A. Rawson, of Bromley, in Kent, with reference to an Orobanche which had come up on a plant of Madame Vancher Pelargonium, bedded out two years ago. The letter stated that the plant had been preserved, and that the Orobanche had this year been very showy; also, that this Orobanche—*O. caerulea*—which usually occurs on Hemp, as far as known does not grow naturally in the neighbourhood. Mr. Berkeley added, that he had been informed by Mr. Hally, of Blackheath, that an Orobanche, not *O. caerulea*, grows there on Pelargoniums.

A pretty golden-leaved Oak called *Quercus concordia*, exhibited by Messrs. Lee, was then noticed; and it was stated that at Sir Hugh Williams's at Bodelwyddan there is a large tree of *Quercus sessiliflora*, which presents a similar appearance, and forms a prominent feature in a lovely view. Attention was next directed to hybrid Pelargoniums between the Scarlet and Ivy-leaved kinds, and it was stated that Mr. Wills had endeavoured to produce such for sixteen years without result, but at last he had succeeded in raising hybrids. One of them, between an Ivy-leaved Pelargonium and Mrs. Pollock, had a leaf like the former, but spangled like a diseased Oak. An extremely curious specimen of a Sweet William sent by Mr. Wilson Saunders, with the leaves forming a cup round the bud, which was blanched in consequence, and a Pelargonium, proliferous from the centre of the trusses, having been pointed out as examples of abnormal growth, Mr. Berkeley read a letter from Mr. D. Wooster on the subject of the exhibition of Fungi in the autumn. In this letter Mr. Wooster expressed his opinion that Fungi are of great importance as an article of food, and that not only have the public much to learn on the subject, but many prejudices to get rid of. As an instance of the latter, he related that when on a visit to a large landed proprietor a few years ago, he found in that gentleman's woods a large group of the beautifully tinted and elegant *Agaricus timetarius*, and much astonishment and alarm were caused by his proposing that these Mushrooms should be cooked. It was only on his giving the assurance that he had often eaten the species with perfect safety that they were prepared, and all who tasted them pronounced them most excellent and delicate in flavour. Mr. Wooster added that he had received a letter from a gentleman, an excellent authority on the subject, in which reference was made to Mr. Berkeley's very interesting discourse on Fungi at the meeting of the Society of Arts on the previous Wednesday; and the writer remarked that he considered two species not mentioned by Mr. Berkeley were among the best as food—namely, *Agaricus atramentarius* and *A. comatus*.

EXHIBITORS' MEETING.—The Council having invited exhibitors to meet them at half-past 1 P.M. for the purpose of discussing the appointment of judges at the Society's Shows, a number of the leading exhibitors attended. The chair was taken by J. Clutton, Esq., and Colonel Scott attended as Secretary. Among those present were Messrs. W. Paul, Turner, Keynes, Lane, G. Paul, Wills, T. Osborn, Barr, C. Lee, Williams, Dobson, Bull, Watson, Waterer, Cathush, Spary, &c. A desire was expressed by Mr. Turner, Mr. Bull, and the exhibitors generally, to afford every assistance and support to the Council. Mr. Keynes objected to the same Judges being appointed every year: Mr. Lane to their being appointed by exhibitors. Mr. Barr thought that the Judges ought in all cases to be men who had been either successful exhibitors or cultivators. Mr. Wills did not agree in this: he considered that exhibitors might have friends, and that the Council should select whatever men they might think best. Mr. W. Paul, who stated his views on the subject at some length, said that it was impossible for awards to give universal satisfaction. The competition for prizes in many cases was very close, and not every prize was won in a canter. Exhibitors watch narrowly the development of points of beauty in their own plants, and endeavour to annihilate defects, and in consequence they know all the points of their own plants, but not those of other exhibitors. Hence they are naturally inclined to consider their own best. Neither exhibitors nor bystanders were such good judges as the Judges who have leisure to examine. The Judges should be honest, efficient, cultivating men—men who did not do right for appearance sake, but for its own. Errors of judgment might occur, but he had never seen but on one occasion a case of dishonesty at an exhibition.

After some desultory conversation it was ultimately resolved that each exhibitor should send in, on or before the 26th inst., the names of five florists or horticulturists whom he would wish to be Judges in the classes he intended to show in at the forthcoming exhibitions of this year.

THE POLYANTHUS.

A GLANCE at such flowers as Hulton's Lord Lincoln, Saunders' Cheshire Favourite, or Adis's Kingfisher, will not fail to convince any admirer of "Nature's sweetest smiles" that such

are the flowers from which the experimentalist may expect to raise by careful crossing improved varieties of this early spring flower.

I do not know that I can advance anything new, merely lessons that I have learned partly from experience and partly from other growers; yet I feel assured that any one following the simple directions I shall give will become a successful cultivator, and to this end the following particulars are essential. First, a suitable aspect. The north or east of a wall or fence or temporary shade, where they will get only the morning sun, is the aspect most favourable for their well-doing. Second, suitable soil; good loam from a field that will grow good wheat, well sweetened by exposure to frost, sun, and air, or good turfy loam well mixed with one-third of either two-year-old well-rotted cow or horse dung, well sweetened by exposure and frequent turning-over—about 9 inches deep of such soil will grow the *Polyanthus* healthy and well.

But the great secret of success lies in deep planting. In making the hole ready for the reception of the plant (which ought to have its roots washed and examined to see that they are all healthy and vigorous, and any decaying parts removed), raise it up in the centre in form of a cone, spread out the roots around it, gather the foliage erect, and fill up to about 1 inch above the collar of the plant. The advantage derived from deep planting is, that the best rootlets growing from the top part of the tap root derive more nourishment from the soil, and are more secure from drought in summer and frosts in winter. It is also necessary that they should have regular attention by frequent stirring, top-dressing with fresh soil, watering when necessary; and as soon as the truss makes its appearance, cover it over with a square of glass firmly fixed in a short stake; this will be a sufficient protection to keep off wet and some insects which injure the bloom.—*DENY (in The Gardener)*.

WOLLATON HALL.

THIS fine mansion, one of the seats of Lord Middleton, is situated in an extensive park about two miles west from Nottingham, and was built in the reign of Queen Elizabeth, with stone brought, it is said on horses' backs from Ancaster, upwards of twenty miles distant—a mode of conveyance which in those pre-railway days was, perhaps, more expeditious, and less expensive than by wheeled vehicles over the roads which then existed. The mansion occupies an elevated position in the park, and is rectangular in form, with a square tower at each corner, whilst from the centre of the building rises another tower, commanding extensive prospects. Eastwards towards Nottingham the town was shut out from view by lofty trees, but is so no longer, 150 of them having been blown down in ten minutes during a terrific hurricane in the end of 1863. Still several of remarkable size and beauty yet remain, and among them a Scotch Fir upwards of 100 feet in height, and a magnificent Beech, besides many fine Oaks scattered over the park, and, on the beautifully-kept lawn near the house, fine old Yews and Cedars once feathered to the ground, but by the orders of a former Lord Middleton they were deprived of their lower branches, and, consequently, of much of their beauty.

In a conservatory on the west of the mansion are the *Camellias*, which are the pride of the place, producing every year thousands of blooms. Some of the plants are from 12 to 15 feet in height, and have stems of remarkable thickness, whilst the profusion of large, glossy, dark green leaves attests their perfect health. They are chiefly planted as bushes in beds of loamy soil, but there are also a few very fine plants trained against the back wall. Hardly as we know the *Camellia* to be—all but hardy out of doors in the south of England—one is hardly prepared for the cool treatment which it receives at Wollaton, for no fire heat whatever is given, not even in such winters as those of 1837-38 and 1860-61. Mr. Pearson has stated (Vol. XII., page 276), the circumstances which first led to the disuse of all fire heat, and that the then Lord Middleton seeing the plants flower as well or better than ever after the former winter, never allowed the house to be heated whilst he lived; Mr. Pearson justly remarking, however, that had they been in pots instead of being planted out the roots might have suffered. It may be added, that had the plants been of less size they would also probably have been injured by the low temperature to which they were exposed, the thermometer falling to 24°; but, above all, their immunity from injury was most likely partially attributable to the growth being firm and well matured, instead of long-jointed and succulent.

The plant houses contain a choice and well-managed collection both of fine-foliaged and flowering plants, among which are good examples of *Sphero-gyne latifolia*, *Cyanophyllum magnificum*, *Marantas*; *Alocasia metallica*, *Lowii*, and *macrorrhiza variegata*; *Anthurium magnificum*, *Theophrasta imperialis*, *Crotons*, and various Ferns; whilst covering the roof of the stove are *Allamanda Schottii* and *Stephanotis floribunda*, which bloom freely and add much to the beauty of the house. In the orangery, of course empty at the time of the writer's visit—in September, there is a fine old *Wistaria* and several large *Camellias*, one plant of the Double White, about 13 feet high, being in excellent health; another plant is about 15 feet high, but not in such good condition.

In the propagating house, besides a variety of new stove and greenhouse plants, especially those most remarkable for the beauty of their foliage, there was a numerous stock of *Gardenias*, which are largely grown for winter and spring flowering.

An extensive range of lean-to fruit-forcing houses consists of three early Peach houses and vineries, together about 42 yards in length, and in which, of course, the crops had been long gathered, two succession Peach houses, 37 yards in length, and 47 yards run of vineries, containing Black Hamburgh, Frontignan, Royal Muscadine, and late Grapes. A small house is also devoted to the culture of *Musa Cavendishii*, and in it the Cotton Plant was producing its pods. For the growth of Pine Apples there is ample provision, and there was in pits and in the succession house a large healthy stock of Black Jamaica, Smooth-leaved Cayenne, and Lemon Queen Pines. Thorsby Seedling is also grown, and is found to swell freely, though not equal in flavour to the Queen Pine. The fruiting Pine stove, a neat span-roofed house, is heated by four rows of pipes for top heat, and bottom heat is supplied by two pipes in a rubble chamber beneath each bed, respectively a foot from the back, and a like distance from the front. The arrangement for filling the evaporating troughs on the pipes for supplying top heat is very simple and convenient; for by simply turning the water on in a leaden pipe extending over the troughs, it issues from a number of perforations in the pipe in as many little jets. Thus the troughs can be filled simultaneously, and the amount of water in them can be regulated to a nicety; the advantages of which are, that on the one hand by quite filling the troughs continuous evaporation can be maintained, and, on the other, if a greater degree of moisture is required to be diffused in the house in a short time, when the troughs are dry, that object can be secured by turning on only a little water at a time, so as to secure its rapid evaporation.

In the Melon house there was a good supply of fruit in all stages, the kind principally grown being the Strathfieldsaye, and for early fruiting the Bromham Hall. The winter Cucumber house was filled with Azaleas, and other plants, but was about to be cleared out. The beds are 2 feet 6 inches deep, and each is heated by a flow and return 4-inch pipe in a chamber beneath, and atmospheric heat is supplied by two flow and two return-pipes. The Cucumbers preferred for winter are Telegraph and Lancashire Witch.

The potting shed, though a place where a very important portion of the work connected with plants under glass has to be performed, rarely claims particular mention, but that at Wollaton presents a feature which deserves general imitation, for it is heated by two 3-inch pipes. How much this must conduce to the safety and success of plants removed from heated structures to be operated upon, as well as to the comfort of the men, need not be insisted on, especially as more than once Mr. Fish has referred to the subject, and pointed out the evils which are apt to result from taking plants from heat into the cold for the purpose of repotting, or of performing similar operations. It is very often want of attention to precautions such as this that makes all the difference between success and failure, although in every other respect the mode of culture may have been judicious and carefully carried out; and though every one cannot have a heated potting shed, yet it is within the power of every one to imitate it by guarding against unnecessarily exposing plants to checks from cold air and cold soil, too frequently followed by cold water. In addition to the heated potting shed there is a room for fumigation, also heated, which must be a very convenient place for effectually and economically disposing of green fly, and other insect intruders, when it may not be desirable or necessary to fumigate a whole house.

The kitchen gardens are very extensive, and remarkable for the high order in which they are kept. Altogether, with the slips outside the walls, they cover an area of about 8 acres.

The centre walk of the walled garden is 12 feet wide, and the cross walks 8 feet in width, and they are all made of great depth, with a drain beneath the centre, and edged with Thrift. On the south-aspect wall, 12 feet high, which is flued, but the heating apparatus is never used, there was a splendid crop of Peaches and Nectarines, and on the north aspect Morello Cherries were bearing abundantly; so, too, were the Apricots on the east wall, and Pears, especially the Winter Nelis, on the west aspect. The whole of the wall trees bore evidence of careful management, as did a number of pendulous queneuille-trained trees on the Pear stock, planted round the quarters, which were filled with excellent crops of vegetables. Between these and the principal walks, however, was planted a breadth of Dell'a Beet, the deep-coloured foliage of which, shining with a metallic lustre, proved very ornamental, and certainly, from the quantity of it grown, there was no fear of falling short of a supply of the roots for salads, or, indeed, any culinary purpose.

The preceding account of the gardens at Wollaton is necessarily very imperfect; much has been omitted that ought to have been noticed, but the time was too brief for a thorough inspection of the place, and it only remains to pay a well-merited tribute to the ability with which it is managed in every department by Lord Middleton's skilful gardener, Mr. Gadd.

CARBOLIC ACID v. GREEN FLY AND MILDEW.

In looking over the "Homœopathic World" lent me to read by a friend, I was much struck with the following article, which I give you at full length, hoping that you will make some remarks upon it.

"GREENHOUSES.—Insects or fly, also oidium, or white blight on Vines, may be prevented by placing a dish containing carbolic acid about the centre of the greenhouse."—HALFAY.

ON RAISING SEEDLING PEACHES.

OF the numerous and refined pleasures offered by horticulture, few are more delightful than the production of new plants from seed. The pursuit is limitless and full of pleasing though often tantalising variety, and no small stock of patience is requisite; but, per contra, a certain reward is given with indiscriminate liberality by nature to the chance efforts of the careless, and to the careful and deeply-laid plans of the skilful experimentalist. The numerous fine varieties of fruits obtained by accident prove this thorough impartiality; the theory of progressive improvement held by Van Mons has been negatived by the result of his labours, very few of the thousands of seedling fruits raised by him remaining to attest by their excellence the truth of his theory. This is encouraging to the beginner, and not disheartening to the experienced; the prizes being still open, and the more valuable from the difficulty in gaining them.

Following at a humble distance the experiments of my father, I have for some years watched with great interest the variation of Peaches and Nectarines from seed, such observations being rendered possible after the introduction of orchard houses; and I now venture to make a few suggestions to your readers, in the hope that the improvement already established may be carried a step farther by others. The Noblesse and Grosse Mignonne Peaches are so excellent that they can scarcely be improved, except in size. These two varieties constitute, therefore, the sources from which improvement may be expected. One of the most desirable qualities to obtain in a new race of Peaches must be precocity in ripening; and one of the earliest of Peaches is the Early Nutmeg, worthless as a fruit, but valuable as a parent. By fertilising this sort with Grosse Mignonne or Noblesse, a large early variety may be hoped for. As a union which may possibly lead to a curious result, I should recommend fertilising the immense Pavie de Pompone and the Fairchild's Early Nectarine with the first-named Peach.

The Petite Mignonne, a pretty early Peach remarkable for its fertility, by judicious crossing is capable also of being made the progenitor of vastly improved descendants. Its union with the Stanwick Nectarine may be productive of some interesting varieties. The Early Anne and the Acton Scot, though now superseded, are well known and available; both varieties may be improved by crossing with large Peaches—such as the Royal George, Noblesse, and Grosse Mignonne. The early Peaches I have named are now superseded by vastly improved varieties

—such as the Early Rivers, the Early Louise, and the Early Beatrice; but they are still valuable as parents, and they may by skilful crossing originate some sorts possessing the requisite faculty of precocity. A seedling Peach has already been raised, which for two successive seasons has ripened from the 6th to the 10th of July, three weeks before the Early Nutmeg, at one time the earliest of known Peaches. This is a great step in advance, and will be especially valuable in Scotland, as a Peach ripening in the south of England in the beginning of July would probably ripen in the early part of August in Scotland, and would most likely ripen on walls in districts where the Peach is hardly to be obtained.

Good Peaches ripening in the Peach season are plentiful enough, and the standard of excellence seems to have been reached in the Grosse Mignonne, the Galande, and the Noblesse; but an improvement may be established in these in point of size and hardness. The Alexandra Noblesse, raised from the Noblesse fertilised with the Stanwick Nectarine, differs from the Noblesse in having crenate leaves and globose glands; and it is not liable to mildew, a point of which the importance will be at once acknowledged by all gardeners who have grown the Noblesse, which has a strong tendency to be affected with mildew. The mixture of the Stanwick has modified this tendency, and has even almost improved the flavour of the fruit. I do not doubt but that the crossing of the Grosse Mignonne with the Stanwick Nectarine will also produce some remarkable results. To obtain an advance in size, the enormous Pavies or Clingsstone Peaches, which are amazing for their size, should be used as parents, and crossed persistently with the Stanwick Nectarine, the Grosse Mignonne, and Galande Peaches, and also with the small early Peaches before referred to.

I cannot lay too great a stress upon the invaluable qualities of the Stanwick Nectarine as a fertilising agent; it is robust, hardy, free from a tendency to mildew, and gives fruit very different from the ordinary Nectarines in size and flavour; and has the additional recommendation—no mean one in an orchard house—of having large and brilliant flowers, a property that should be always considered in starting an orchard house. The experiment of crossing Peaches with Nectarines is very interesting, the produce being given without any regard to parentage, Peaches producing Nectarines, and *vice versa*. The French pomologists, or at least some of them, deny this fact; but as I have undoubted proof of this eccentricity, I must beg to differ from "Messieurs les Pomologues," and to assert that the best evidence can be given of the indiscriminate nature of seedling Peaches and Nectarines. As interesting and distinct races of Nectarines for crossing with Peaches, I may mention the New White and the Pitmaston Orange.

The late Peaches, of which the Boudin, Téton de Vienne, and Desse Tardive, may be selected as the types, have a great tendency to drop their fruit before coming to maturity, except in very favourable seasons. This fault is probably due to the fact that the tree has finished its growth before the fruit is fully ripe, and with the cessation of the circulation of the sap, the power of the fruit to derive nourishment from the tree is weakened. To obviate this defect, the experimentalist should select varieties of Peaches or Nectarines which continue growing to a very late period; successive generations will produce improvement in size and flavour. An American Peach named Poole's Late Yellow will hang on the tree until the middle of November; Thomas's November, Pride of Autumn, Baldwin's Late, and the Heath Clingsstone are November Peaches, and if crossed with the Stanwick Nectarine or the Noblesse and Grosse Mignonne Peaches, some singular sorts will no doubt be originated, if planted in a dry and cool house, with sufficient heat at command to exclude frost. As Peaches may be preserved a long period, the time may not be far distant when the dessert on Christmas-day will not be considered complete without the noble-looking fruit which has been the glory of the summer and autumn.—T. F. RIVERS, Sawbridgeworth, Herts (in *The Gardener*).

PELARGONIUM RETICULATUM.

THIS unique and singularly beautiful variety of the Nosegay section has leaves elegantly netted or traversed, during the winter and spring, with golden veins upon a green ground, and throughout the warm dry summer months finely marked with a tracery of green network upon a golden ground. Its large and compact trusses of rich crimson bloom are in the style of

Stella, but it is a great improvement upon that variety in its habit of growth, which is densely compact and dwarf.

It is well adapted for flower-garden groups and pot culture for conservatory decoration, also for terrace vases.

This interesting plant appears to be the only variety in cultivation with golden netted leaves, being distinct from the *Ciconium reticulatum* of Sweet, which is not found at present in trade collections.—E. G. HENDERSON & SON.

WORK FOR THE WEEK.

KITCHEN GARDEN.

ENDEAVOUR to mulch round crops in rows, if possible, doing so being much better than watering. Observe how well Strawberry beds look after being mulched; short grass, old tan, rotten dung, half-spent linings from the hotbeds, indeed any sort of litter, will do for this purpose. Nobody thinks of leaving the ground about a newly-planted favourite tree unmulched the first season, and Peas, Beans, &c., are just as much benefited by mulching as newly-planted trees. In the American ground most of the subjects there planted grow naturally in shaded places, and they will luxuriate in the hottest seasons if the beds are thickly covered with grass, fern, moss, or any other sort of mulching. *Asparagus*, this is the very best time in the whole year to apply salt or saline manures to this crop. The drainage of common sewers, stables, cow houses, and laundries, and even pond water made thick with soot will all be now appropriated to the plants. *Broccoli* for autumn may yet be sown; Grange's Early White and the Covent Garden are good varieties. *Cauliflower*, it is not advisable to sow later than the beginning of this week for late autumn use. Sow very thinly, as you can hardly expect to be able to prick-out next month, so that the crop must stand in the seed bed till fit to plant out permanently. *Endive*, about the end of May or the beginning of June is the best time to sow this very wholesome salad for autumn use, and as you ought to sow every three weeks till the middle of September, it will only be necessary to sow a pinch of seeds each time, scattering them very thinly. All summer crops, of whatever nature or kind, should be sown very thinly if any of the plants are to be afterwards transplanted. They may, it is true, be thinned-out if they happen to be too thick; but if the weather is dry at the time much injury may result, and on the whole it is better to sow thinly in the first instance. *Lettuces* and other succession crops, continue to sow.

FRUIT GARDEN.

Thinning-out and regulating the summer growth of Gooseberry, Currant, and Raspberry bushes is not so much attended to as it ought to be. Examine Peach trees that suffered from frost last season, and carefully remove every piece of gum and canker with a sharp knife. Endeavour to prevent the progress of the green fly, and see that the roots are not suffering from want of moisture, otherwise much mischief will be produced by a wet autumn. Destroy caterpillar and black fly on Cherry

trees by giving a forcible washing to the trees with clear limo water. In training Raspberry canes there is no system so profitable as keeping the bearing shoots at a regular distance from each other in a straight row, and by tying them to two straight rails. Whatever system of training is adopted, no time should now be lost in removing all those young shoots that will not be required for bearing wood next season.

FLOWER GARDEN.

On the average of seasons we seldom experience late frosts after the middle of the month, and having of late so much sunny weather, we may safely begin planting out half-hardy plants in the flower garden. Beginning with the oldest and hardiest sorts, if these plants have been properly managed in hardening them off (and we have seldom had a better season for this), they ought now to be in good condition for turning out, except, perhaps, in low, damp, or late situations. Make active preparations, therefore, to commence the work on the first wet day. If the beds have been dug over lately, and the plants have firm balls of earth about their roots, it will be better to plant more deeply than should be done in firm ground, as the fresh-dug beds will settle a little. Every plant ought to have a good watering at the time of planting, and if the weather is dry they will require to be often watered till they are once established; but recollect that "water often and little at a time" is one of the worst precepts of the old school, even with pot plants in winter, and still worse as regards out-of-door crops in summer. In nine cases out of ten slight surface-watering at this season does actual mischief, and plants are safer if left to take their chance than when submitted to such bad gardening. Remove the flowers and seed pods from American plants as fast as they become shabby, which will add materially to the strength of the plants. Give the beds a good flooding of water. The pegging and tying-out of the plants should be no longer delayed. Double Wallflowers, Mule Pinks, and some common Dianthus, Alyssums, Phloxes, perennial Iberises, and many kinds of dwarf Cistus and Helianthemums may be propagated under hand-glasses in a shaded situation, and will be found very useful next spring. Keep Auriculas free from weeds, occasionally watering and stirring the surface. Offsets may be taken off if rooted; place them round the sides of the pots in compost before recommended. When the seed vessels of Polyanthus are swelled, should any decayed bloom remain these must be removed, as they are liable to retain moisture to the detriment of the seed. Remove the awning from the Tulip bed, and let the flowers be exposed to the weather. When seed is not required break off the capsules. Do not neglect the beds because their beauty is over, but remove all weeds as they appear. After a shower, water with liquid manure between the rows of Ranunculuses. Do not wet the foliage. Unless Carnations are carefully tied the wind will break or twist off the shoots; worsted is the best material to fasten them with. As laterals are thrown out from the sides they may be pinched-off, in order to strengthen the other flowers. Let the stakes be put to the Dahlias as soon as convenient; when delayed much longer the root is often injured by the insertion of the stakes.

GREENHOUSE AND CONSERVATORY.

A mixed greenhouse is an indifferent place for ripening-off the growths of Camellias and Chinese Azaleas, and they should be removed to a close pit kept shaded in the middle of bright days. If there are spare frames or pits, all the Heaths and most of the other hardier greenhouse plants will grow in these far better than in the best-constructed greenhouse, and in that case the greenhouse can be converted into an intermediate stove, or a show house, where only plants in flower are to be kept during the summer. In the summer treatment of the conservatory three grand points have to be observed—viz., never to let the air become too dry, if possible, all the summer; to keep the house as cool as the weather will allow; and never to let the plants be crowded together.

STOVE.

Very many of the free-growing plants will now want another shift into larger pots, and as they must occupy more room you must remove some of the more hardy sorts to the greenhouse or some other place. Now and in the middle of winter are the advantages of an intermediate house, one having a temperature between that of a stove and greenhouse, most apparent; this is the most useful house that can exist about an establishment. Stove plants now require to have large portions of air, plenty of room, and as much light as the house will admit, in order to ripen their growth properly. Woody plants and large specimens should not be shaded, if possible, but all the

young stock may have some light shading thrown over the glass in the middle of the day when the sun is strong. See that none of the plants suffer from the want of water.

PITS AND FRAMES.

When the finer plants are brought into these you may keep them a little closer, and, probably, many of the plants will want a little shading in the middle of the day at first. After the pits are well watered in the afternoon give the whole a good sprinkling with the syringe, not, however, if it has been a dull cloudy day.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

The rain of which there was a prospect did not come, and scarcely ever had we a drier week and warm as well. We have been forced to water some Peas that seemed as if they needed something, but by means of surface-stirring and mulching, as in the case of Cauliflowers, everything stood better than we expected, which was fortunate, as our water is becoming scarce.

Cleaning Tanks.—Sometime ago we were obliged to a correspondent for telling us of charcoal as a means of sweetening foetid water. We charred some large boles of trees, and placed them in the water, and they have much improved it; but as the water was getting low, we had the tank cleaned out, as it had a large deposit of rotten leaves, which had been blown into it in the course of two years. This tank receives most of the water from a range of sheds and glass houses. We preferred it to be open to keep the water soft, but the neighbouring trees have grown much since then; but for the softness of the water we would prefer a covered tank, as no leaves or rubbish can be blown into it.

We have another large reservoir of water not far from it, which will be very valuable until we have rain. That is merely dug out in the clay, and is supplied with the surface water that falls on the glass of pits and the gravel round them, the water being conducted in open culverts in the gravel to cesspools, whence it is taken beneath a road to this rough-made reservoir; the road itself being made on a slope, so that nearly all the water that falls on its hard surface finds its way quickly to this reservoir. Before we hit on this plan most of the water about pits, &c., found its way to dumb wells in the chalk 40 or 50 feet in depth. These wells took away the water until the chalk became slimed over, and then the water rose in the wells, and after heavy rains used to find its way to our stoke-holes, and caused the expenditure of much time and labour to wheel it out. By cutting off all such rain water from these wells, and taking it from hard surfaces to cesspools communicating with the pond-like reservoir, we keep our stokeholes dry, and have a large quantity of useful water, which, though it goes in muddy off the roads, soon settles down and clears itself. We are generally scarce of water every summer, but there need be no scarcity if we have tanks or reservoirs to collect what runs off hard roads or walks.

A good rain now would do wonders in this neighbourhood in garden and field. There have been heavy thunderstorms at no great distance. Those perched on a hill must expect often to see rains falling heavily in the valleys, whilst they are privileged with none, and hence in such cases water is to be husbanded if much is done in gardening. We can recollect of a small tap, and the half of a barrel standing beneath it, being all the means available for watering. Our tanks and reservoirs are now pretty fair, but we would rather double than lessen them. Just think of the water that might be saved when it pours along hard walks 3 or 4 inches deep! We have nothing to say against metal, stone, and other culverts, but for catching surface water on roads and walks nothing is so economical and so little observable as a shallow curve in the gravel, say 15 or 18 inches wide, and the centre 2 or 3 inches deeper than the general level, and which difference is rarely noticed unless when the rain water pours along to the cesspool, from which it is taken to the reservoir.

Circumstances compelled us to do more mowing than we intended, and the grass was at once taken to a place where we intend to do away with winter stuff, and have a trench cut out to assist Vegetable Marrows and Cucumbers. But for the pressing nature of the affair we would have had the trench cut, so as not to have to mow the grass, &c., twice; but as it is, the distance will be short. Let beginners bear in mind, that in utilising short grass it is best to use it rather fresh; it is very

unpleasant to work in a fermenting heap of it. The rankest dung is nothing to it. When used as it often is for linings, care must be taken that the steam and gases from it do not penetrate into the frame or pit. Its heat will keep tolerably equable a long time if it is duly mixed with long dryish litter.

Watering was the chief thing attended to, and that moderately, as unless when absolutely necessary we prefer surface-stirring and mulching.

FRUIT GARDEN.

Watered Strawberries out of doors that were coming into full bloom. From this they received only a tithe of advantage, as the sun was so bright; and no watering is like rain, as then we have the cloud and dullness along with it. With gentle rains the Strawberry crops promise well. Of some of the earliest kinds a few of the forward blossoms were blackened with the frost, but plenty remained to produce heavily.

Peaches and Nectarines out of doors, went over these, removing foretrot shoots, fingering where there were signs of fly, and giving a good lashing with the engine the first thing in the morning, as it is hardly safe to do so in the evening or the afternoon as yet. These trees, protected merely by a few twigs, are but moderately supplied—in some places thin, and in other places a thicket of fruit. Perhaps we hardly gave them so much attention as when we had no orchard house.

Orchard Houses.—We have been twice over these, and have not yet nearly thinned them enough. From the latest one the other day we took two bushels of small fruit of Peaches and Nectarines, and far too many are still left; but the Peaches when a little larger will be useful, and will do little to distress the tree until the stoning has commenced. From what has lately been said by Mr. Brabant and the inquiries of several correspondents, we are induced to say a few words on thinning, and first on *thinning flowers*. We did nothing in that way this season, and could hardly have found time if we had desired to do so. We felt sure that many more would set than we wanted, and resolved to wait until then for thinning. We have found thinning the blooms of much value under two circumstances. First, when there was a great display of bloom buds, and yet we had reason to fear that the wood was green and imperfectly ripened. In such a case the removing with pointed scissors or a sharp-pointed knife the side and more backward buds, left a greater share of the more matured sap for the diminished buds, and setting was a matter of more certainty. The second case in which thinning was even more effectual was in that of old trees, and where we had reason to believe that the action of the roots was rather in arrear of the swelling and expanding of the buds. In such a case we have known trees that had their fruit buds thinned set well and ripen their crop well; whilst when left thick, as they showed, they either set imperfectly, or, if they set thickly, they often afterwards gradually disappeared, dropping off by degrees until few or none were left. It seems to be at the early stage in such a case that nourishment is scarce, and that is more effectual when directed to few channels instead of many. As the season advances and growth becomes more luxuriant there seems then to be no difficulty in getting the fruit to swell. The hitch is just at the setting and afterwards. In the case of old Noblesse trees we repeatedly found that leaving the tree to itself was followed by a meagre crop, and a good crop was the result of a free thinning of the bloom buds, leaving the best-placed. When trees are moderately healthy and not too old, or the roots too deep, and the wood fairly matured, as in orchard houses, the thinning of the blooms may be looked upon as a substitute for so much *thinning the fruit*, and therefore may be dispensed with by those who like to see clusters of young fruit like ropes of onions. It would not be advisable to leave these thus thick and too long; nevertheless it is not bad policy, after a little thinning, just to wait a little and see what fruit is disposed to take the running, and then prefer that to the smaller ones. We may thus bring in the principle of natural selection to assist us in thinning. The chief point is not to wait so long as to get the trees exhausted with a lot of fruit that must be removed. We find this waiting plan a good one with Plums, as many of them after seeming to set will drop, and it is as well to see which takes to swelling freely before we thin much. On this account we do not care much to thin Plum buds, even of trees in pots, and a very heavy crop of Plums does not seem to distress a Plum tree so much as an overcrop the Peach. As a general rule, however, a fruit tree will not be overtaxed with impunity. To fill a gap we greatly overcropped a rather old Vine last season, but it will nearly require this season to recruit its exhausted energies.

In such weather all trees in pots and Strawberries in pots required a great deal of watering. When Strawberry pots can be set on the ground, as in the front of our orchard houses, it is a good plan to set them on fresh turf reversed, with just a sprinkling of leaf mould to make it level for the pots. Some thus set when removed were found to have their roots firmly imbedded in, and traversing more than a square foot of turf. There is no standing water in such a case, as in a saucer.

Opportunity was taken in the morning to thin Grapes and regulate Vines, and in the late vinery we have removed most of the plants, and as we could not keep the Vines back more without injuring the bunches, we will regulate the ventilation, and give fire heat to keep it warmer as the Vines come into bloom—the time when those in late cool houses need the help of a fire most, especially in dull weather. The other time when a little fire heat is most useful for them is in winter, when dryness and airiness are essential to the good keeping of the Grapes. We use little water in the way of syringing Vines, but we like to give them one lashing after the first dressing, removing extra shoots, &c.; but Peach trees we syringe frequently, though our water is not so pure as we would wish for that operation, and therefore we content ourselves chiefly with damping the paths and floors.

In the Peach house, of the four lines of Strawberries we have removed the highest one over the pathway at back, as it was shading the back wall, and a plant or two was showing signs of the red spider. It is always advisable to avoid mounting ladders for watering as soon as possible. The Strawberries on that shelf, so close to the glass, would have been apt to suffer from red spider in such scorching weather had we not for the space of 18 inches opposite the shelf dulled the glass with whitening. We also removed to a pit a fine row of Strawberries at the top of the late vinery just referred to, where they would have swelled very well, but they were becoming too shaded to be well flavoured, or even bright-coloured. We have heard Strawberries spoken of as being watery, &c., when the gardener had no place to ripen them, except under the shade of other things. They will swell there, but they will not be high-flavoured. After putting Strawberries in every imaginable place, we question much now whether giving them a handy house or pit to themselves is not on the whole the most economical and the best in every way. On the shelf referred to the berries were swelling nicely, but they were soft and watery owing to the shade, and of course the labour in moving them cost something. The firmest and best Strawberries we have had this May were ripened in the open air from pots, the fruit being nearly ripe before setting outside in a sunny place. In firmness and flavour the berries were superior to what are generally grown and gathered with out-door treatment. To have the best flavour Strawberries should be gathered when the soil is comparatively dry. Even out of doors we have gathered and kept them thinly spread out before rain came on. The same kind of Strawberry gathered out of doors in sunshine, and after rain, is quite different in flavour.

ORNAMENTAL DEPARTMENT.

Work outside has been heavy, and we shall be busy in making ready beds and borders for bedding plants. We always advise taking these matters easy; nothing is gained by planting before the ground is moderately warm. We again reiterate our old advice, Dig down plenty of sunbeams before you begin to plant out. About the 22nd of May last year many of our readers lost thousands. We had not a plant out, and therefore lost not one. Our plants are mostly in the ground, exposed, but capable of being protected in a moment, and are growing with little trouble where they are. Being in the earth they need little in the way even of watering, and when removed will scarcely feel the moving. Partly by necessity, as our ground is not yet ready, and partly by choice, because we attribute so much importance to the airing and turning of the soil, we will for a few days be more anxious to have the ground in good order, than to put the plants out so early. Some years ago a friend of ours turned out strong plants of Verbenas in the middle of April, and a considerable amount of trouble was required in protecting them with twigs afterwards. We turned out plants not better—hardly so good, in the last week in May; but before the end of June our plants were in every way far in advance of the early-turned-out plants.

A few words now to those who will, however, plant early. If you wish for immediate effect plant thickly, even if you should afterwards have to cut the half of them out. If you chiefly aim at autumn effect plant much more thinly. For instance, in the first place we would plant fair plants of Tom Thumb Pelargonium from 6 to 9 inches apart. In the latter

case we would plant from 12 to 15 or 18 inches apart. In dry weather, such as still threatens to continue, give water merely around the roots, and keep the dry soil to the surface; and if the leaves are distressed at all, syringe them instead of deluging the soil with water, and thus cooling it immediately.—R. F.

COVENT GARDEN MARKET.—MAY 20.

SOME good English Peas have made their appearance. Prices continue the same as last week.

TRADE CATALOGUES RECEIVED.

J. Westley, Floral Nursery, Blisworth.—*Descriptive Catalogue of Bedding Plants.*

E. G. Henderson & Son, Wellington Road, St. John's Wood.—*Catalogue of Bedding and Softwooded Plants, New Plants, &c.*

TO CORRESPONDENTS.

.. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix upon the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

BOOKS (E. W.).—The Garden Manual may suit you. You can have it free by post from our office if you enclose twelve postage stamps with your address. (A. W. L.).—There is no work upon the culture and uses of herbs.

ACUCRAS (W. Wormold).—The flowers were male.

MONSTROUS GROWTH OF ROSES (J. Subscribers).—Roses throw up wood growth in the centre of the flower and chiefly from two opposite causes—poverty, and over-luxuriance from excessive manuring; sometimes, also, from there being too many flowers on a plant. The Strawberry blossoms seem blackened by frost. The first on the 7th affected some with us in the same way.

STRIKING DOUBLE WALLFLOWER CUTTINGS (J. L.).—Cuttings of double Wallflowers may be inserted now in sandy soil under a hand-light, in the open air in a shady place, or in a pot kept shaded a little until growth has commenced.

SULPHATE OF LIME (T. Catechpool).—As a garden manure it has been found useful sown over lawns, but is also beneficial to Turnips and Potatoes sown over the surface, and dug in before inserting the crop; 3 cwt per acre is sufficient.

MUSHROOM CULTURE (J. Subscribers).—We have a little much on Mushroom-growing that we must at present be brief, referring to previous numbers and volumes for variety of material, form of beds, &c. The best way of making a bed depends on the materials. We have just formed one in an open shed of 15 inches deep of litter dung, well trodden, and 3 inches of horse droppings on the top. The best material is horse droppings with a little short litter in it, moderately dried before making the bed, and in that case from 12 inches thick will make a good lasting bed. This, well beaten, shon't be spurned when it is put on the bedline

and about 85°. The spawn should be inserted just beneath the surface, in pieces the size of walnuts, or a little larger, and 9 inches apart. When the heat is stationary, not rising, cover with 1½ inch of rather stiff soil, beat firmly, and leave with a smooth surface. Cover with a little hay or litter to keep the soil uniform in heat and moisture. A shady place, a shady shed, a cellar, &c., will be better than a house in summer. In winter and spring the best heat is 60° to 80° in the bed, and 55° to 60° in the house, and from the time of spawning you may expect to gather in six or eight weeks.

GRAPE SPOTTED (L. M. C.).—The berries are severely attacked by the spot—an ulcer as called by gardeners. Three out of every four of the berries should have been cut away as soon as the size of No. 4 shot. The roots are unable to supply sap to them in sufficient quantity. Remove every berry as soon as the spot appears in it, and thin the berries of all the bunches severely. If the roots are outside theinery, cover the surface with fermenting dung.

GRAPE REMAINING ON THE VINE (Reader).—The hanging of late Grapes, say until March, does nothing to prevent the wood ripening, and so far as we can judge, after many years' practice, does nothing to enervate the Vine. The Grapes hanging on the Vine receive enough of juice to keep them plump from the slow action of the sap of the Vine; but if kept until the spring flow begins to rise, the berries of the bunches would crack and decay. In moderately late Vines the Grapes are cut before there is a chance of bleeding; but in very late Vines, where bleeding would be likely to follow from cutting late, the Grapes may hang before the sap rises vigorously; but before then the Vines should be disbudded, say by February, leaving only the buds wanted, but in that case the Vines must not be cut until they are in full leaf. We have done this frequently, and with no result, and with no bleeding. Of course it would be as well for the Vines if the Grapes were cut when ripe, but the above will show that the Grapes may hang long and yet the Vines not suffer. In unforced houses there will be no danger of bleeding if the Vines be cut towards the end of February. The Vines will move little if the temperature is not higher than from 40° to 45°.

PRUNING (Idem).—The whole question of pruning and curtailing growth lies in a nutshell. Where there is abundant room we may with every propriety allow more free growth; but when we wish as much fruit as possible in little space on a tree, then we concentrate the fruitful energies of the plant so as to produce fruit buds instead of mere growth. We have never met with the proofs that the fruit spur of an Apple or Pear tree is formed in one season, blooms the second, and fruits the third. In many cases by pinching shoots we have clothed the lower end of this season's growth with buds that bloomed and fruited in the following season, when shoots not operated on had nothing from point to base but wood buds. What are fruit buds, rarely burst as wood buds only, if the fruit bud was matured. This is often only imagined to be the case, when the fruit bud has perished, and the wood buds near it have thus obtained more vigour than they otherwise would. Except in such cases, fruit buds will develop into blossom, and it is equally rare, that "ordinary" leafy buds apparently open in bloom." Of course, seasons, &c., do much, but still can also do something, and hence practical experience is better than mere theory, though both are good if kept in their own place. It is not only in stone fruit, but in almost every other kind of hardy fruit, that the same fruit bud does produce fruit only once, but others are produced near it, and the noobservant come to the conclusion that the same bud continues to produce. Singular exceptions often happen, but these do not make a rule. We once transplanted a large espalier Apple tree, and though it had plenty of fruit buds, it did not open a fruit bud, or even a wood bud, for not a single leaf did it present the following summer. Nevertheless, we found there was enough of movement of sap to keep the tree alive, as the bark kept fresh and green when cut. The tree was transplanted about Christmas, and it took a whole twelve-month's rest, not producing a single leaf, but it broke at the usual time the following year, expanding both fruit buds and wood buds, and produced more than half a bushel of Apples. We should not expect such a result in general circumstances. We do not exactly see what you are aiming at in the somewhat singular questions you propose as to vegetable development, and we fear we can give little explanation of the phenomena without going deep into phytology.

FUMIGATION (D. H.).—The "Tobacco grains" used were those advertised by Mr. Pooley, Sussex Wharf, Wapping, London. We cannot say how they are prepared.

GRASS-EDGING CUTTER (J. W.).—Any of the implement makers who advertise in our columns could supply you. Write to them for particulars.

FLOWERING DOUGAINVILLEA GLAURA (T. M.).—We do not think the plant will flower in June. Being large it may do so if you have secured a good growth, and now expose it fully to light and keep it dry for a fortnight; but if it is now growing freely we hardly expect you will see it flower before August, if then. Secure a good growth, expose that growth to the full sun, give abundance of air, preserve a dry atmosphere, and give no water at the root so long as the leaves do not flag. Bottom heat is not necessary. The temperature may safely be 55° at night, and 70° by day without sun, and from 80° to 85° with sun and abundance of air.

STEPHANOTIS FLORIBUNDA (J. D.).—Stephanotis floribunda would not succeed trained over wire basketwork in a sitting-room. It is a stove plant. We would employ *Ipomoea hederifolia*, which is not so common as it deserves to be.

SELECT VARIETATED IVIES (Idem).—It is hard to tell which are the best two variegated Ivies, as taste differs considerably. *Hedera helix marginata argentea* is a fine silver-margined sort, and *Hedera helix aurea maculata*, a golden one. Two others equally good are *H. helix alba lutescens*, and *H. helix minor lutea*. We prefer the small-leaved sorts, two of them are *Cullisii* and *palmata aurea*.

STRIKING ROSE CUTTINGS (Idem).—The proper time to make Rose cuttings is directly after the flowering is past. The wood is then ripe, and the cuttings root freely and safely if put in before the shoots have commenced to grow.

TREATMENT OF RHODODENDRONS AFTER FLOWERING (Agnes).—The flower trusses as they fade should all be broken off between the finger and thumb. In this way the plants will not be weakened by the production of seed, and will bloom better in the following year. Give the plants thorough waterings in dry weather, and mulch the surface of the beds with the mowings of the lawn to the depth of 2 or 3 inches. All this should be attended to at once.

HARDINESS OF ILLICUM RELIGIOSUM (F. G.).—It is not hardy except in a warm situation in the south of England. A wall with a southern aspect and protection in severe weather would probably suit it.

STRIKING BANKSIA AND GRUVILLEA CUTTINGS (Idem).—Cuttings of these will succeed without bottom heat if covered with a bell-glass and kept close and shaded, and in a house where there is a temperature of 70°.

DURATION OF CLIANTHUS DAMPieri (Idem).—This *Clianthus* is the same with you as with us—viz., a biennial. It is generally accepted as a perennial, but it does not succeed with us from cuttings, nor thrive well after flowering once.

TULIP TREE BLEEDING (A. F.).—As the bark has the appearance of being burnt, we should think the tree had received a blow, or that the bark has been otherwise damaged, hence the bleeding. If the scar were caused by canker there would not be any oozing out of the sap. We do not think it will destroy the tree, but we would at once cut out the damaged portion of the bark quite into the quick, apply Thomson's styptic to the whole of the wound, and continue the application until the bleeding stopped, then cover the wound with grafting wax made of Burgundy pitch, 1 lb.; common pitch, ½ lb.; beeswax, 3 ozs.; and mutton suet, ½ oz., melted and put on with a brush while warm. It should be made to cover the edges of the bark, and should be repeated at intervals so as to stop any cracks.

WATERING STRAWBERRIES WITH LIQUID MANURE (K. F. A.).—It is of great benefit, and may be given once or twice a week after the blossoming is over until the crop is gathered, more especially if the weather be dry.

RIVINA LEVIS (F. D.).—This is a dwarf-growing shrub of no great merit as a flowering plant, but attractive by its orange berries. It is not so good as *R. humilis*; the latter has white flowers, the former pale pink flowers. It is of very easy culture, requiring a compost of light turfy loam two-thirds, and one-third leaf mould, with a free admixture of sharp sand. It succeeds in a cool stove, having a light and airy situation. It is not worth a place in a small collection unless grown for a particular purpose, or for its berries, which are pretty on a well-grown plant. It is readily increased by seeds in a hotbed.

REMOVING FRUIT TREES IN SEPTEMBER (H. O.).—You may safely remove all the trees and bushes you name at the end of September, taking care in removing to preserve as much of the roots as possible, and not shaking off more of the soil than that which falls away readily. Any adhering should be retained, and the roots ought to be protected as much as possible from sun and air. Plant again without delay, and give a good watering.

PROPAGATING WHITETHORN (Idem).—It is raised from seed. The haws should be gathered and put into a pit the same as Potatoes, only in a thinner layer, and covered with soil. They remain thus a year and are then sown in beds, November being a good time. The seeds germinate in spring. Thorns do not come well from cuttings. The seed does not vegetate until the second year.

PEAR-TREE BLOSSOMS NOT SETTING (Idem).—The flowers may have been destroyed by frost. If not, we think top-dressing with manure or rich compost, and giving thorough supplies of liquid manure in dry weather would assist setting.

SPROUTING BROCCOLI (A Subscriber).—The Purple Dwarf and Tall Sprouting Broccoli supplied by the firm you name are the sorts recommended in our number of April 23rd.

PANSY (Viola).—The flower you enclosed was very shrivelled, but not so much so as to prevent our discerning the colours. They are not unusual, and run too much into each other.

MUSHROOMS TOO THICK (—).—We have several times been obliged to use less strong manure, as the Mushrooms became too thick to be easily cooked. We presume that is what you mean by having the Mushrooms nearly all pith. If too thick to fry cut them in slices and they will answer very well, but will not look so well as thinner Mushrooms with plenty of pink laminae or gills beneath. Use more litter with your droppings and manure, and the Mushrooms will be thinner. We see no particular spot on the Cucumber leaf, except scorched spots made by the sun striking on the leaf when still damp. You may have the disease called "spot," but we did not perceive it. Give air early, and leave it on all night at present.

FLOWER GARDEN PLANTING (R. G. H.).—The finest bed of *Coleus* we ever saw was at Woburn, and it was edged with *Cineraria maritima*. We saw the same bed edged with Mrs. Pollock *Pelargonium*, fine, but not equal to the former, for the *Cineraria* made such a chaste finish. Your Cloth of Gold *Pelargonium*, and *Lobelia* banded between it and the *Cerastium* outside, would do well; but so far as we can judge, nothing equals the *Cineraria*, or the white-leaved *Centaurea* next the *Coleus*; but, of course, it is well to try different plants.

BARBE DE CAPUCIN (Old Subscriber).—This, the blanched leaves of Chicory, may be produced in many different ways, all that is requisite being to keep the roots in a dark place with a temperature of from 50° to 60°. Seed may be sown from April to July, and the culture may be the same as for Endive. The French, according to Thompson's "Gardener's Assistant," adopt the following modes of treatment—"The seed is sown thinly in April or May. In November or December, one or several beds of light sandy soil, or well-decomposed dung, about 2 feet in width, and 3 inches thick, are formed in a cellar. On these is placed a row of Chicory roots laid on their side, with the crowns outwards; next comes another layer of earth of the same thickness as before; then another row of roots, and so on. The mild and equal temperature of the cellar, and the want of light, soon occasion the production of blanched leaves, which are cut as soon as they have attained a sufficient size. Water must be given as required, if the soil used is too dry. Near Paris, a more expeditious method is pursued; beds of hot dung are made up, and the roots of chicory, tied up in bundles, are placed in an upright position upon the beds, and watered from time to time, so as to keep them moist. Another method of blanching without taking up the roots, consists in sowing in drills from 6 to 8 inches asunder, and covering the Chicory in February with 4 or 5 inches thick of earth, or with double that thickness of leaves. In three weeks or a month afterwards, according to the season, it pushes, and as soon as it appears above the additional soil or leaves, it is cut over by the original level of the ground. In this way the leaves are very white and tender. Another mode of blanching consists in

boring holes in a cask with an auger, in rows 3 inches asunder, and filling it up with alternate layers of sand and roots, with the crowns protruding through the holes. The cask is then placed in a dark cellar, and the sand is then moistened if it becomes too dry. In this way several cuttings of blanched leaves may be obtained till the roots are exhausted. This method is sometimes adopted on board of ship."

ERECTING A PINE PIT, &c. (A. Francis).—We must give you the same modified answer as we gave to another correspondent in page 192. To make the most of such a house, 30 by 12 feet, you might have the front wall 4 feet high, and the back wall 9 feet high, and a path of 3 feet at back, with shelves against the back wall. The bed would occupy the whole front, 2 feet high in front, and 2½ feet behind. What would be more convenient would be to have a path 2½ feet wide all round, and a bed of 7 feet wide in the middle, then the front wall from the floor would be 6 feet, and the back wall 11 feet high. The first plan would afford most room for the Pines, but you could not get at them so well; but by sinking 2 feet as you have done, your front wall would only be 2 feet above the ground level, so that by tilting the sash you could easily reach the plants in front. For a fixed roof it will be best to have the bed in the middle of the house. For such a house we would advise you to have hot water instead of flues, and the simplest plan would be to take three flows for top heat and return them under the bed for bottom heat.

TORREYA GRANDIS (T. C.).—This is a Taxod or Yew-like tree, and perfectly hardy, but of slow growth. It would be interesting to know what soil it succeeds best in, and whether it has been proved hardy everywhere.

POTTING AND DIVIDING MAIDENHAIR FERNS (M. H.).—The best time to pot them is when they are beginning to grow; the ball may then be reduced to any extent necessary to get it into a smaller pot, or if the plants are large they may be divided at the time of repotting. March is in general the best time to divide the plants; but this operation may be performed at any time if a good quantity of soil be preserved with each division. It is not advisable to pot Ferns in the autumn.

BIRD'S-NEST FERN BLACKENED (Idem).—Your plant is not kept sufficiently warm. Give more heat and avoid syringing over the fronds; it is impatient of water on them whilst in a young state, and condensed moisture frequently causes their disfigurement. Keep the plant near the glass, but shaded from bright sun, and maintain a brisk heat of 55° at night and 75° to 80° by day, with plenty of moisture, but not over the fronds. Afford a moderate amount of air, but avoid cold currents.

MAKING A WOODEN ROOF WATERPROOF (A Constant Reader).—We presume the boards forming the roof overlap each other to some extent, and in that case they will only need to have two coats of boiling pitch and coal tar, 1 lb. of common pitch being added to every gallon of coal tar. Apply with a brush and sprinkle the roof lightly with dry sharp sand, and the wood must be dry, otherwise the pitch and tar will not adhere. Unless the wood be dry and well seasoned it will crack and let in the wet, therefore such roofs are generally covered with the felts made for the purpose.

APHELANDRA PORTEANA CULTURE (Titmouse).—This plant requires a stove temperature, and that may be from 55° to 60° at night in winter, and from 65° to 70° by day; in summer the temperature should be from 60° to 65° at night, and from 75° to 80° by day, and higher with sun and air.

A position near the glass is essential, likewise a fair amount of ventilation. It succeeds in a compost of one-third turfy sandy peat, two-thirds fibrous loam, and a free admixture of silver sand and pieces of charcoal from the size of a pen up to that of a hazel nut. Provide good drainage, remove all the old soil parting readily from the roots, and use a pot rather small for the size of the plant. The potting should take place in March, and a moist heat with a close atmosphere should be maintained until the plants become re-established. Water sparingly until the roots are working freely in the fresh soil, then water more freely, but be careful not to over-water at any time, and do not give any until it is required, at the same time do not allow the foliage to flag from the want of water. If bottom heat is at command the plant will be much benefited by being plunged in it for some time after repotting. If the plant grow well shift it into a larger pot in June. When the plant flowers it should be well supplied with water until the bloom is past, then keep it dry, and afford a season of rest, cutting the plant down, and when the new shoots are a few inches long repeat. If the plant do not flower be careful not to saturate the soil with water, but give no more in winter than is sufficient to keep it in a healthy state, but dry rather than wet. Afford abundance of light and air.

LESCHEAULTIA CULTURE (Idem).—A cool airy greenhouse, and a position near the glass without shade are requisite. Use a compost of fibrous sandy peat with about one-sixth of silver sand, and the same proportion of charcoal broken, and not larger than a hazel nut. Good drainage should be given, and the collar of the plant ought to be kept rather high in the centre of the pot. In potting be careful not to injure the roots, and remove no more of the old soil than that not occupied with the roots. The size of the ball will determine the size of the pot to be used, which should only admit of a little soil being added all round the ball. Pot rather firmly, but not very tightly. Water sparingly until the plant has recovered from the potting, and then give more copious supplies, but avoid heavy waterings. If the plant is young it may be potted in June, the first potting taking place in March; but if an old plant the time of potting will be regulated by the time of flowering, the plant being rested for awhile. Cut in any irregular growths before repotting. Young plants should have all irregular growths stopped up to July, when stopping should be discontinued. From June to October the plant will do better in a frame or pit than in a greenhouse, the pot being set on coal ashes, and abundance of air given, especially at night. Be careful not to over-water in winter, and keep the reverse of a moist, close atmosphere, affording a position near the glass and plenty of side room. It will be sufficient if frost be excluded.

GRAVEL ON WALKS NOT SETTING (Idem).—Your gravel is too loose from its being free from clay or loam. We do not know of anything so likely to make it bind as to sprinkle it with some loamy sand, and after the first heavy rain roll well with a heavy iron roller. Roll frequently whenever the weather is wet. We think a good rolling would make it firm.

NAMES OF PLANTS (T. J. L.).—We cannot identify plants from their leaves only; we must have flowers. (*J. T. B.*)—*Thalictrum alpinum* (Alpine Meadow Rue). (*J. E. P.*)—*Orchis morio*. (*E. G. R. F.*)—1, *Saponaria ocymoides*; 2, *Saxifraga aizoon*; 3, *Garden Phlox*; 4, *Euphorbia cyparissias*; 5, *Geranium pratense*; 6, *Potentilla geranioides*; 7, *Cerastium grandiflorum*; 8, *Saxifraga hypnoides*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending May 19th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

GAME FOWLS.

ADVERTING again to the two articles on Game fowls in the number of the 23rd of April, the writer of the first of these seems to hint that I prefer a feathery bird with a broomy tail, whereas, on the contrary, I advocate a short, close, hard, and scant feather, both in body and in tail. A great many good cockers' birds, with the open or spread tails carried high have the very hardest and shortest feather, and good feather is not at all confined to the birds with the drooping, falling, Malay-like tails. The true type of the old English cocker's Game fowl is best seen in and near Manchester, Wolverhampton, and London, at which places the birds are of a different type from our large, heavy exhibition birds, being smaller, harder, and of greater endurance. These birds have, in general, neat short tails, carried well up and open or spread; the sickle feathers with a short curve, and not nearly straight, as in some exhibition strains. The extreme type in the latter birds puts one rather in mind of the Malays. I maintain that the very best

birds are to be bred from the best cockers' strains just named, and not from the large, heavy birds.

The present type of our exhibition birds is one made of late years expressly for exhibition, and unlike the old style of bird in their increased size and weight; and great attention is paid in breeding them to very scant feather and to the form of tail, which latter point is the least important one in a fighting bird, so long as the tail is not feathery or broomy, with a lot of curved "side streamers" in addition to the "leaders," which is very bad, as every judge well knows, and none better than I do myself as an old breeder.

I have already stated that the "whiptailed" are the favourites at exhibitions, being considered neater birds; but cups and prizes at exhibitions are not in all cases a guarantee of thorough gameness, though some exhibitors seem to fancy that they are. The form of tail that I prefer is not so very essentially different from the usual form of tail in prize birds, but I like tails more open, carried higher, and more sickled than the extreme exhibition type of the whip tail. I well know that many whiptailed birds are good and fast birds; but still I am convinced that, as a general rule, "a drooping tail shows a drooping spirit" in a Game fowl, and such tails have the feathers falling together too much, and do not show the proper shape of the

tail. I like to see the whole of the tail boldly shown out, and not concealed by its falling together in feather, as if half the feathers were plucked out, or wet with rain, or as if the bird were cowed. Exhibitors will, however, of course, keep to their own tastes as to tails, and I shall also retain that which I prefer as having a more thoroughly English appearance.

As to the yellow-skinned, willow and yellow-legged exhibition strains, every one must allow them to be the handsomest birds of all as to colour, and the only birds that possess the true "golden-tinged red" plumage; but beauty of colour is not gameness, and the white-skinned birds possess a superior share of endurance and courage to the yellow-skinned, which are all too soft in their nature, as the old cockers well knew. I have already stated elsewhere that the yellow-legged Piles, if red-eyed, are both good and quick birds, and are undoubtedly the handsomest Piles of all; but they are known not to be equal to white-legged Piles, when the latter are well bred, in either courage or endurance. Again, some exhibitors fancy that their willow-legged Black-breasted Reds are first-class fighting birds; they may become so if crossed with Brown Reds and other good colours for the pit; but when pure bred very few willow-legged Black-breasted Reds are real hard cockers' birds, and cockers seldom breed this colour at all. In and round Manchester, Wolverhampton, and London you will seldom see any but blackish-legged, dark-combed Brown Reds and Dark Greys, and white-legged Black-breasted Reds with the light wheaten hens. These are the true cockers' birds, are all white-skinned, and seldom have the drooping Malay type of tail at all, but have open tails. Pure-bred willow-legged Black-breasted Reds are in general inferior in courage to all Game fowls, except to the yellow-skinned sorts with yellow eyes, which are the worst Game fowls; these willow-legged Black-breasted Reds being much inferior to the Brown Reds in courage, and also to Dark Greys, Piles (white legs), good Ginger Reds, good Red Duns (white legs), and to good Whites (red eyes, white legs), and also to the blackish, carp brown, and white-legged birds of their own colour. The blue-legged breeds of Game fowl, though white-skinned, are inferior in general to yellow-skinned exhibition birds, and stand about the last, or nearly so; but there are exceptions to all these rules, and some strains of all colours prove good at times. Red-eyed blue-legged Red Duns and Duckwing Greys are often very good quick hard birds, and I think Westmoreland has some very good blue-legged Game fowls.

To the names of breeders which I gave before, I add, to show the type of exhibition birds that I admire most, the following—viz., Mr. Fletcher's Brown Reds, Piles, and Duckwings; Mr. Charles Challoner's Brown Reds, Piles, and Duckwings; Mr. Harry Adams's Brown Reds and Piles (not now an exhibitor); Mr. Aykroyd's Brown Reds and Duckwings.

I have already stated that I like the blackish-legged dark-combed Brown Reds of these strains, and the white-legged Piles better than the yellow-legged for gameness; also that I think Mr. Statter's the best Brown Reds of all, and Mr. Brierley's and Sir St. George Gore's the best Black-breasted Reds. Such as these are the style of birds that I would award prizes to, and in addition to these I might name Mr. Burgess's Game fowls, also Mr. Billing's, and Mr. A. B. Dya's Brown Reds, though I have not heard quite so much of the birds of the last-named exhibitors as of those of the others that I have mentioned before.

As to Game cocks breaking out of their pens and fighting, it is so common an occurrence that it is scarcely worth notice, and penning always inclines them to be fierce and quarrelsome when near each other. If good quick birds they would, of course, kill one another in a few minutes, instead of injuring each other, as two farmyard cocks would do, or two great Malay cocks. The cockers' strains at the places I have mentioned are the true pure-bred Game fowls, and not the great heavy half-bred Malay things, that one may often notice at some of our exhibitions.

I think a Black-breasted Red cock, perhaps of Sir St. George Gore's strain, which took a first prize, was about the best bird at the last Birmingham Exhibition. All will easily admit that the red-combed red-faced strains of Game fowls possess far more beauty than the gipsy-combed, smoky-faced breeds, but the latter are well known to be harder and gamer, and will stand more steel than any red-combed birds. Besides this, gipsy combs and faces are the proper and original type in Brown Reds, Dark Greys, Dark Birchens, and some Black Game fowls. For beauty of colour I have always preferred the red-eyed red-combed strains, more especially Black-breasted Reds, and

Piles, with yellow (1) and willow (2) legs, both red-eyed. As to the beauty of tails, all broomy side-feathering in them is very bad-looking indeed, as all fanciers of Game fowls know, and drooping wings in Game fowls would be ridiculous. I should have said before, that willow-legged Duckwings have in general also proved gamer than willow-legged Black-breasted Reds.

I quite agree with "YORKSHIRE" as to my remarks on Game fowls being rather opposed to modern exhibition ideas, and being as such rather "old-fashioned," but I cannot see that they are in the least prejudiced. The present style of exhibition birds on the average I consider to be decidedly inferior both in gameness and quickness, also in endurance, to the old style of bird, and I do not think they are so "deep game" as the average of the best old cockers' birds. Cock-fighting reached its zenith about 1825 or 1826, and birds have been less game I fancy ever since 1832. Well-matured progression in breeding is all very well, but by crossing different colours together I think breeders rather retrograde, and obtain mongrel mixtures, though I highly approve of crossing different strains of the Game colour, which is the way to approach perfection.

The willow-legged red-combed Brown Reds are, of course, finer in colour than the old true bred gipsy-combed blackish-legged breed, but for courage and endurance are inferior, though fast birds at times, and are too soft in flesh. The darker Brown Red hens are the better, as long as the dark brown colour is perfectly distinct from any Black; and the more gipsy the comb and face, the more perfect in blood are such hens, and the cocks fight best. The old Shropshire Reds, I have heard, were the best birds of their time in all qualities, and were quick and not slow, though not so quick as the Cheshire Piles were. Crossing them with Black-breasted Reds and Duckwings made them slower, though redder in colour; the cross with the Cheshire Pile (white legs) made them quicker and redder in colour, and lighter also, and gave them the white nails. Undue size and legginess clearly result from the very objectionable Malay cross, which is more particularly observable in some of the strains of the large Nottinghamshire Black-breasted Reds, with long willow legs.

The articles in THE COTTAGE GARDENER in 1857, almost entirely refer to exhibition birds, and to beauty of colour, and not to gameness, or to the old style of bird, and the yellow and willow-legged breeds, undoubtedly, stand first of all for beauty of colour, and almost exclusively possess the true "golden-tinged red colour" in their Red breeds; but beauty of colour is not what the old cockers required.

The articles contributed by me since September 18th, 1866, tend to recall to recollection the older and gamer style of bird, and refer less to the now well-known exhibition-type of bird about which it is scarcely worth while to write very fully. No doubt the majority of exhibitors would vote for the whip tails, not so the cockers I think, of the old style at all events. I dislike the Malay cross, which I am sure has been most freely used to produce our larger and leggier type of present exhibition birds. This style may suit exhibitors, but most cockers. I think, much dislike it, and I cordially dislike the slightest approach to Malay blood or type, though, of course, no cocker at all, but merely an "old-fashioned fancier" of Game fowls of the gamest type.—NEWMARKET.

We have another communication from "NEWMARKET," in reply to "YORKSHIRE" and Mr. Goodall, but the essence of the reply is, that he abides by his opinions expressed in our columns. We must decline inserting more upon the subject.—ED.

POULTRY SHOWS—COMMITTEES—RULES.

As the Marylebone Cricket Club has its acknowledged rules, and is the authority upon that game, might not Birmingham be made the "head centre" of the poultry world, and have, and issue rules to be adopted and followed by all poultry clubs and committees in the county and country towns throughout England?

Secondly. Of any poultry club, I would suggest that no exhibitor should be a member of the committee. If this were generally carried out we should not hear any remark about unfairness or selfish interest.

Thirdly. I would further suggest, that unless a certain amount of subscriptions can be obtained no cups should be offered, but money prizes only, and these prizes in each and every class of poultry should be equal.

Fourthly. As much as possible one show should avoid clash-

ing with, or being held too near, another in the neighbourhood—to wit, Newmarket, July 1st; Stowmarket, July 3rd; Dewsbury, August 19th; Whitworth and Rochdale on the same day.

Fifthly. The date for entries to close should be limited to fourteen days prior to the day of exhibition. Some lists give as much as thirty days, others only seven. This is an irregularity that admits of alteration.

Sixthly. I would admit poultry only to be exhibited. I will here ask, What is poultry? Any dictionary replies, Domestic fowls bred and fed for the table. What is a Pigeon? A gallinaceous fowl of the genus *Columba*; therefore, admissible to poultry shows. To these two varieties, then, poultry shows ought to confine themselves.—GALLUS.

HULL AND EAST RIDING POULTRY EXHIBITION.

THE entries for this Show consisted of 350 pens, and the character of the specimens in almost every class was such as is very rarely met with. A very remarkable feature was (the time of year being taken into consideration), that scarcely a dozen empty pens could be found. The condition of the birds, too, was excellent. The only drawback to the general appearance of the Exhibition arose from the peculiar construction of the building, which prevented the light being equally dispersed, and consequently some of the bottom rows of pens were placed to serious disadvantage for careful inspection. The Committee appeared most desirous to do everything they possibly could for the well-being of the birds, and as the weather was remarkably favourable, the Meeting proved most successful.

Perhaps it would be difficult to call to mind any show in which the Game classes abounded with so many first-rate specimens as the one just closed at Hull, and we can say that never were Game fowls shown throughout in such unexceptionable condition—in fact, most of the principal breeders of Game had specially reserved their strength to secure the very excellent silver cups that the Hull Committee had appointed as chief prizes. So faultless was the condition of the specimens, that we are informed of the first nine Game cocks that were "handed," every one on this point proved faultless. It was quite evident that the owners, well knowing how much depended on this point, and how certain they were to meet with the most severe competition, had done all that the most careful management could do to insure success; consequently, those poultry amateurs who neglected to attend the Hull Show have lost such a treat in Game fowls as even a long course of years may not again supply. *Spanish* were excellent, and for the season they were shown in unusually good feather. The *Grey Dordans* and *Cochin-China* classes were alike good. A pen of Partridge-coloured *Cochins*, winners of the marble bust of Vesta, were especially so. The *Brahmas* and Golden-spangled *Hamburghs* were placed in so imperfect a light, that they were difficult to distinguish, still it was evident there were many specimens of great merit. The Pencilled *Hamburghs* were such as are only rarely to be seen, even in this district, where these varieties are most carefully cultivated. "The Variety class" was most interesting, and there was a good entry as to numbers. Game *Bantams* were in full force, and seemed one of the most attractive to visitors. The Black *Bantams* at Hull were very numerous and especially good.

The *Aylesbury Ducks* were represented by giant specimens from the yards of those eminent breeders and exhibitors, Mrs. Mary Seamons and Mr. J. K. Fowler, both of Aylesbury, and the keenest competition, as might be expected, ensued. "The variety class" of Ducks embraced *Mandarins*, *Bahamas*, *Pintails*, *Carolinians*, and other choice varieties.

The *Pigeons* were especially meritorious, and the *Rabbits* were considered of unusually high merit.

The interest manifested in the Hull Show was made evident by the fact that many exhibitors were present from places as distant as London and Bristol.

The Judges of Poultry were Mr. H. Adams, of Beverley, Edward Hewitt, Esq., of Birmingham; and for Pigeons and Rabbits, Mr. E. Hutton, of Leeds. A list of their awards appeared in last week's number.

EPWORTH POULTRY SHOW.

THE third annual Exhibition of Poultry, Pigeons, Cage Birds, Rabbits, &c., was held at Epworth on the 8th of May. The Poultry and Pigeons were not so numerous as last year, but on the whole the quality was better. The show of Spangled *Hamburghs* was very good, but the Pencilled were very inferior birds. *Spanish* were shown in very good condition. *Game Bantams* were first-class, as also *Bantams* in the "Any other variety" class. There was a splendid show of Rabbits, Mr. Wagstaff, of Thorne, exhibiting some ten weeks old, and having ears 20½ inches long. Cage Birds were shown in considerable numbers. The day was delightful, and the attendance of visitors good.

Mr. H. Beldon officiated as Judge for Poultry and Pigeons; Mr. J. Spinks, Gainsborough, and Mr. J. Hammond, Epworth, for Rabbits; and Mr. T. H. Capes, and Mr. S. H. Hudson, Epworth, for Cage Birds.

The following are the awards:—

SPANISH.—First, J. Thresh, Bradford. Second, T. C. & E. Newbitt, Epworth. Highly Commended, W. Bearpark, Ainderby Steeple.

DORKINGS.—First, A. M. Aspinall, Althorp. Second, J. Boyes, Epworth.

GAME.—First and Second, F. Sales, Crowle.

COCHINS.—Prize, J. H. Dawes, Birmingham.

HAMBURGHS (Spangled).—First, S. & R. Ashton, Mottram. Second and Third, T. C. & E. Newbitt. Highly Commended, W. Bearpark; J. F. Loversidge, Newark.

HAMBURGHS (Pencilled).—Second, W. Benson, North Wheatley.

GAME BANTAMS.—First and Medal for best pen of Poultry in the Show, E. Toder, Little Carlton. Second, T. C. Harrison, Hull. Third, E. Toder.

BANTAMS (Any variety except Game).—First, T. Burgess, Brighstone (Pekin). Second, S. & R. Ashton (Black). Highly Commended, T. C. Harrison, Hull (Silver-faced).

ANY OTHER VARIETY.—First, S. S. Mossop, Long Sutton (Buff Polish). Second, Mrs. Cross, Briggs (Creve Coeur). Third, C. Addey, Epworth (Dark Brahmas). Highly Commended, G. W. Boothby, Louth (Gold Polish).

ANY VARIETY.—Cock.—First and Second, F. Sales (Game). Highly Commended, Mrs. Cross. Commended, S. & R. Ashton. Hen.—First, J. Thresh. Second, S. & R. Ashton. Third, T. C. & E. Newbitt. Commended, Mrs. Cross, Appleby; A. M. Aspinall; J. Seadmore, Epworth.

DUCKS (Any variety).—First, T. C. Harrison, Hull (Carolina). Second, A. M. Aspinall (Rouen). Highly Commended, S. & R. Ashton (Carolina); R. Brown, Belton (White Muscovy).

PIGEONS.

CARRIERS.—First, J. Hawley, Bingley. Second, H. Yardley, Birmingham.

PORTERS.—First and Second, C. Addey, Epworth. Highly Commended, J. Hawley; F. Key, Beverley; T. C. & E. Newbitt. Commended, H. Yardley.

TUMBLERS (Any variety).—First, F. Key (Almonds). Second, J. Thompson, Bingley (Yellow Mottled). Highly Commended, J. Hawley; H. Dundas, Epworth; C. Grivil, jun., Thorne; H. Yardley.

JACOBS.—First and Medal for best pen of Pigeons in the Show, T. C. & E. Newbitt. Second, J. Thompson. Highly Commended, C. Addey.

TURBITS.—First, J. T. Lishman, Gillingham, Bradford. Second, J. Thompson. Third, R. Wilson, Thirsk. Commended, F. Key; J. Thompson.

BARBS.—First, H. Yardley. Second, R. Siddal, Sheffield. Highly Commended, Rev. H. C. Russell, Doncaster.

FANTAILS.—First, J. Hawley. Second and Commended, T. C. & E. Newbitt.

TRUMPETERS.—First, J. Hawley. Second, T. C. & E. Newbitt. Commended, R. W. Bell, Hull.

ANY OTHER VARIETY.—First, R. Wilson, Thirsk. Second, J. T. Lishman. Commended, H. Yardley.

SELLING CLASS.—First, T. C. & E. Newbitt. Second, J. Thompson. Highly Commended, J. Hawley; H. Burnip, Epworth.

CAGE BIRDS.

CANARY (Yellow or Buff).—First and Second, Rev. H. C. Russell. Highly Commended, Rev. H. C. Russell; T. Maynard.

CANARY (Marked or Mule).—First and Highly Commended, Rev. H. C. Russell. Second, T. W. Dawson, Epworth. Commended, J. Wagstaff, Thorne.

GOLDFINCH.—First, R. Jackson, Epworth. Second, Rev. H. C. Russell.

LINNET.—First, Rev. H. C. Russell. Second, E. Glew, Epworth.

Highly Commended, T. Maynard, G. Batty, Epworth; J. Wagstaff.

ANY OTHER VARIETY.—First and Second, Rev. H. C. Russell (Waxwing and Starling). Third, Miss Read, Epworth (Parrot). Highly Commended, Rev. H. C. Russell (Siskin).

RABBITS.—First, A. H. Easton, Hull. Second, C. Grivil, jun., Thorne.

Rack.—First, J. Wagstaff. Second, A. H. Easton. Highly Commended,

C. Grivil, jun.; F. Roberts, Thorne. Commended C. Rayson, Prestwich.

Doe.—First and Second, F. Roberts. Highly Commended, A. H. Easton.

J. Wagstaff. Commended, C. Rayson. *Extra Stock* (Ten weeks old),

length of Ears 20½ inches).—Highly Commended, W. B. Hudson, Epworth.

RABBIT-JUDGING.

BEING a Rabbit-fancier, and in the habit of attending exhibitions, I am not surprised at many of the exhibitors being dissatisfied with the manner in which Rabbits are judged. In the first place, too often men are appointed to judge who do not understand them, and the results are the greatest dissatisfaction and confusion, and often the downfall of what otherwise might be flourishing exhibitions.

Rabbits, to be judged properly, require measuring and weighing if length of ear and weight are required; but if they are judged for all properties, length, breadth, and carriage of ear should be considered; also boldness of the eye, shape, colour, and weight. If Rabbits were judged on these points there would be more entries, an increase of exhibitions, and general satisfaction would be secured. Let committees attend to this, and they will find it advantageous. I would also suggest that judges' names should not be inserted in the catalogues previous to the exhibitions.—A FANCIER OF TWENTY-FOUR YEARS STANDING.

MALFORMED CHICKEN.—A chicken was found with four feet, four wings, and one head. Unfortunately it was dead when found, and must have been so for some days. It was a *Cochin-China*. It was found in the grass run amongst the sand, and my last chickens here hatched a week ago. It is in a good state of preservation in a bottle in spirits, and any reader of

"our Journal" or the Editors may have it for a museum.—
HENRY ENSOR.

PACKING EGGS.

A MONTH ago I purchased from Mr. J. Fletcher, Stoneclough, near Manchester, a sitting of fifteen Game eggs, and which were sent from Mr. Fletcher's runs, South Staffordshire. These, after their arrival, were put under an ordinary-sized Black Red Game hen, and on Wednesday last I had thirteen chickens from this clutch. Two of the eggs were unimpregnated. Today (Saturday), one of the chickens has died, but all the others are strong birds. I may mention that the eggs were packed in a small tea chest, having some straw in the bottom, then the eggs were put on this, some chopped hay covered and separated them from chance of collision, and after the eggs were carefully packed in this manner, the box was filled with straw, and the lid tied down firmly. Seeing that the parcel had a journey by railway of about 250 miles, and then the rumbling through the streets before delivery, I think the system of packing must be effectual.—BLACK RED.

[We shall be glad to hear from you.—EDS.]

HOW TO BREED PURE LIGURIAN QUEENS.

As many of the readers of "our Journal" may not be in a position to purchase the discovery of Mr. Koehler, I think they might in the meantime try the plan of an apiarian friend of mine for preventing his Ligurians from crossing. It is this. As soon as a young queen is hatched out in a nucleus box a number of pure Ligurian drones are selected for her companions, and confined along with her in the box for two or three days. Then, on the afternoon of a fine day, when all other drones in the apiary have gone to rest and the queen is judged ready to take her wedding flight, the hive is opened. As might be expected, the queen and her companions immediately avail themselves of their liberty, and a pure breed is secured. Should the first tour prove unsuccessful, the hive is again shut up, and not opened until the following afternoon.—
M. J., Lockerbie.

[The plan above described is well worth trying, and although I find myself precluded by my promise of secrecy from declaring how far it resembles Mr. Koehler's process, I may state that I have written to Mr. de Romein enclosing a copy of "M. J.'s" communication, and expressing my regret at being compelled to decline receiving further subscriptions.—T. W. WOODBURY ("A DEVONSHIRE BEE-KEEPER"), Mount Radford, Exeter.]

TEMPORARY SUPPORT OF COMBS.

In reference to your note appended to remarks on frame hives by "J. J. S.," I have to commend the method, at which he hints, of using indiarubber bands for the temporary support of combs placed in frames, having myself adopted it for two summers with much success. Common tape, of a suitable width, may also be used for the same purpose. It is tied tightly over the top bar, and when unloosed may be pulled up and removed at any time without disturbing the frame.—
J. LOWE.

ADDING QUEENS.

PLEASE give me advice as to the following plans:—1st, Place a Ligurian queen and brood comb in the centre of a hive, putting it in place of a black stock. 2nd, The same as the above, only the comb to be empty.

Will the returning bees be likely in both cases to receive the solitary queen as their own?—C. A. J.

[The returning bees would in either of the supposed cases be nearly certain to destroy the strange queen if exposed without protection to their tender mercies. The use of a queen cage might render success possible, although by no means certain.]

OUR LETTER BOX.

BOOKS (*Omega*).—"Bee-keeping for the Many" will suit you. You can have it free by post from our office, if you enclose six postage stamps with your address.

PIGEON BOOK (*A. V. D. M.*).—We believe Mr. Brent's "Pigeon Book" to be on the whole the best and most useful work of its kind ever published. It can be had from our office, free by post, if you enclose twenty stamps with your address.

HENS LAYING SOFT EGGS (*B. C.*).—There is some mistake in your feeding. We are followers of Nature, and therefore laugh at burnt oyster shells as poultry food. We call it food, because there is no doubt the shell is formed from that which is eaten. It cannot, however, be properly done unless the body is in a healthy state. Mortar and old ceilings, bricklayers' rubbish, &c., are very good for forming shell. The hens must also have green food and some whole corn, as the husk contains lime. If your birds are enjoying a good grass run, we can only advise a dose of castor oil all round. If they are in confinement give them plenty of lettuce, and some large sods of growing grass, cut with plenty of earth. If they are in a pen put a barrowload of earth in a heap, and let them search it over. They will often see medicine where it is hidden from us.

HEN BROODY (*E. C. N.*).—Do not torment her any more; her longing for the honours of maternity will soon disappear, and she will lay again. When she is again broody let her sit. We always think it is cruel to prevent it, and we are sure nothing is gained by it.

FATTENING SPRING CHICKENS (*Miss J.*).—Put up your spring chickens at once. They should have been put up before, and will never again be so valuable as at the present time. Every day will help to diminish the value of spring chickens. You may grow any shrub or climber not poisonous in your aviary; you cannot help the birds eating them. We do not think the ants will do any harm.

VARIOUS (*R. J. W.*).—If the Dorking cock have sufficient merit to make it desirable to keep him, do so by all means, even under the circumstances you name, but for this year only. Brahmas' eggs are not as a rule longer in hatching than others. The extra time is often caused by the eggs being kept so dry; the chickens cannot get out, and many die imprisoned in the shell that, with the least assistance, would have made their way into the world. Another cause is, that hens sometimes get to the sitting nests, and lay a day or two after the other hen began sitting. The Ducks' eggs were "all behind," but we should attribute it to the same cause as the delay in the other case. It cannot be too strongly impressed on all amateurs and others, that regular and successful hatching cannot be looked for unless the eggs are regularly and thoroughly wetted.

GROWTH OF BRAHMA CHICKENS (*G. N.*).—Your Brahmas are growing very well, and if you keep them at the present rate they will leave nothing to desire in the way of size. We have some of the same age, and the pullets are larger than the cocks. It is positive nonsense to talk of keeping pullets from laying with a view to improving them for exhibition, because it cannot be done.

BRAHMA COCK (*B. P. C.*).—The cock will not or should not be disqualified.

FODDER (*Quiz*).—All cattle, horses, and sheep eat white clover. Cows will not eat buttercups, notwithstanding the vulgar idea that they make the butter yellow. Buttercups flourish where the soil is rich and moist. The grass there is also abundant and nourishing, and it is the rich herbage which imparts the colour.

LITERARY (*J. B. B.*).—The attempt was made, and occasioned a heavy loss to the able conductors. A sufficient number of subscribers cannot be obtained.

HULL AND EAST RIDING POULTRY SHOW.—The second prize for Black Bantams was awarded to Messrs. Tonkin & Tuckey, Norfolk House, Gloucester Street, Bristol.

FOOD FOR PIGEONS (*Fantail*).—The Pigeon is a granivorous bird, and therefore must be fed on grain. Other food may be used as additions, but not as substitutes.

AMERICAN COLLATERAL PLAN (*A Fifeshire Bee-keeper*).—An ordinary straw skep (empty) is placed in front of the stock when the bees begin to get busy in May or June, and in good seasons a second skep is placed in front, and by taking the backmost skeps away after the bees have taken to those in front, a good supply of honey is obtained. The objection to this plan is that the bee-keeper obtains none but dark-coloured honey in old combs, whilst there is great risk of so large a proportion of drone combs being built in the added hive as to preclude the possibility of prosperity for the future.

MR. KOEHLER'S DISCOVERY.—Amongst those German apiarians whose testimony to the success of the Koehler process has come under my notice, none is so well known to English readers as the Baron von Berlepsch, whose evidence on the point is most conclusive. Writing under date of the 27th of November last, the Baron declares that he has tested the discovery at six different times, and that on every occasion it has proved successful.—A DEVONSHIRE BEE-KEEPER.

FOOD FOR A SQUIRREL (*Poplar*).—Give your Squirrel bread soaked in milk fresh every day; also nuts, apples, and any other kind of fruit. It would not be safe to place a Squirrel in an aviary with Canaries.

SCIENTIFIC WONDER (*T. H. P.*).—We have not seen it, and therefore can give no opinion.

BUTTER BECOMING RANK (*Quirymahl*).—We do not think the buttercups are the cause, for cows avoid eating them, and they exist in quantity in most of the best pastures we have; but there are other weeds that sometimes affect the milk, one of the worst being a sort of bulbous plant, called ramps or ramson, a near ally to the garden onion or garlic, which grows in moist shady places. We have also known much damage done by allowing the cows to eat the waste cabbage and other greens thrown out of gardens at this season, and in the autumn some (but not all) cows partake, to their injury, of horse chestnuts. Many other causes tend to render milk ill-flavoured. We are, however, promised further information on this head.

POULTRY MARKET.—MAY 20.

POULTRY is still very scarce, but there are signs of a greater supply of small chickens. They will, doubtless, now come in more abundantly.

From observations taken near London during the last forty-one years, the average day temperature of the week is 68.2°; and its night temperature 44.5°. The greatest heat was 91°, on the 28th, 1847; and the lowest cold 25°, on the 29th, 1865. The greatest fall of rain was 0.97 inch.

BEET AS A BEDDING PLANT.

WITH Mr. Robson's Hertfordshire friend I quite agree as to the comparative merits of Beet as a dark-foliaged plant. I have grown the variety known as Barrett's Crimson Beet for the last ten years, and can always obtain it so genuine from the seedsman that every plant looks as if turned out of the same mould, and I have rarely ever known one run to seed. It can be sown so early as to give a longer season of effect than either Coleus, Iresine, or Amaranthus, and it certainly is, taking one season with another, the most effective plant of the whole. Its lustrous dark-crimson leaf, with just a shade of bronze playing over it, is alike beautiful in sunshine and in rain.

I have also grown Dell's Beet, which is, if anything, a shade darker, but lacks the bronzy lustre of Barrett's. Dell's is more dwarf and pointed in the leaf, as well as less recurved than Barrett's. Let any one plant a bed of Centaurea, put a single line of Beet round it, and finish with the chaste and graceful *Dactylis glomerata* or *Polemonium caeruleum variegatum*, and he will have a bed very difficult to be excelled. These Beets, whatever prejudice may exist against them as stray vegetables in the flower garden, are most effective, and are within the reach of the million, who cannot grow the tender dark-foliaged plants.

The Iresine did beautifully here last year, planted in almost dung, and well supplied with water. In dry poor soil it is dingy and shabby. A series of vases placed at the back of a border and planted with Centaurea, having a line of Iresine connecting and encircling the vases and hiding them, so that the Centaurea appeared to rest on the Iresine, was very much admired. I think those who have heavy rich soil will find the Iresine well worth growing, especially in wet localities.—D. THOMSON.

P.S.—I may remark that Beet does much the best when sown where it is to remain in rich soil about the last week in April, and if well through the ground at the ordinary bedding season it soon makes good its appearance among its compeers, and long outlasts them in autumn.

STANDARD NOSEGAY PELARGONIUMS FOR WINTER BLOOMING.

Few subjects of recent introduction are more beautiful than some of the Nosegay Pelargoniums, and when grown as standards or half-standards I question if there is anything more valuable for the winter decoration of the conservatory, and the supply of flowers which they afford for cutting is surprising. Having a large conservatory to make gay in winter I have usually grown a selection from Mr. Beaton's and other varieties to flower from October to May, and nothing could better answer the purpose.

In adopting the standard form of training I have not been guided so much by the vigorous habit of growth which these Pelargoniums possess as by the noble and ornamental appearance for conservatory decoration which

this form presents; for though the dwarf broad specimens usually seen at the metropolitan exhibitions are fine examples of the cultivator's skill, yet I am of opinion that the length of time and trouble required to grow such specimens, and the inconvenience in arranging that form to advantage in a miscellaneous collection of plants as compared to the standard, are against its being adopted by the majority of gardeners for the above purpose. The standard plant also produces larger trusses, finer flowers, and of greater substance than the dwarf.

Feeling sure that the merits of this section of Pelargoniums entitle them to a much more extended cultivation than they now receive, I will give a list of the varieties I have found most suitable, with a few remarks on their culture. When this appears in print it will be time to procure such varieties as Duchess, Amy Hogg, Glow-worm, Excellent, Orange Nosegay, Black Dwarf, Magenta Queen, Salamander, Pillar of Beauty, Searlet Gem, Madame Rudersdorff, Cybister, Dr. Lindley, The Clipper, Princess Lichtenstein, and Madame Chardine.

Presuming these to be small plants in 3-inch pots, shift them at once into 6-inch pots. Drain the pots well, and use a rich soil composed of one-half heavy turfy loam, the remainder leaf mould, rotten manure, and sand in equal proportions. After potting water well, and keep the plants close for a few days, either in a frame or pit without artificial heat. Select the strongest shoot, and train it to one stake, taking off all others with flower buds as they appear. As the plants become established more air must be given, and in three weeks after potting they will be sufficiently rooted to be shifted into 9-inch pots, in which they may be allowed to bloom. Use the same sort of soil as before, but coarser. They may now be plunged up to the rim of the pot in half-decayed leaf mould or old tan in a sheltered but sunny spot where the water can drain easily from them. By the last week in August take off the tip of every plant, which will cause them to break at the top, allow two, three, or four shoots to remain, according to the strength of the plant, and when these are about 4 inches long, take the tip out of each of these. When they have again broken into growth, which will be towards the middle of October, they may be taken to the conservatory, where they will grow rapidly and flower freely the whole winter. On some of the weaker-growing sorts it may be necessary to thin-out the flower trusses, or they will exhaust themselves. In February give a rich top-dressing, and a liberal application of manure water twice a-week will be of service to them. About six trusses of different varieties will fill a large flower stand or vase, and when mixed with *Adiantum* (Maiden-hair Fern), they are very ornamental in the drawing-room at Christmas.—T. REEBO, *Hackhurst*.

FRUITING STRAWBERRIES FROM THE PREVIOUS YEAR'S RUNNERS.

THE fruiting of a Strawberry plant from runners of the previous year is, I think, an element in the estimate of the comparative value of different sorts, second only to flavour and size. Perhaps the results comprehended in the following

ing table, compiled for my own guidance in selection, may be of service to others. It is only of value, of course, in relation to such seasons as the past. The soil is a sandy loam, 15 inches deep, with just sufficient clay to insure its cracking very slightly in dry weather when the surface has not been previously stirred with the cultivator. The subsoil is clay.

With the exception of Dr. Hogg Strawberry, which I did not remove till spring, they were all transplanted in balls in the month of September last year. Had this been done in the middle of August the results would have been much more favourable, both as to frequency of bloom and strength of plant.—FRUIT-EATER.

INSECTS.

(Continued from page 357.)

THE green *aphis* on Peach, Plum, and other fruit trees, on Roses, and all kinds of trees, shrubs, and plants in the open air, is best overcome by dusting them with tobacco powder; and now that we have preparations of tobacco duty free, the expense is not a serious obstacle. Tobacco has long been known to horticulturists as a powerful agent in the destruction of insect life, but the heavy duty on that of foreign or colonial growth, and the almost total prohibition of growing it in this country, prevented horticulturists from using it extensively, although the best, safest, and most easily applicable remedy for insect enemies.

In applying tobacco powder in the open air, the tree, shrub, or other plant should be lightly sprinkled with enough water to make it wet, and the parts affected with *aphis* should be dusted with the tobacco powder by means of a distributor, which is made of indiarubber in the form of a wine decanter or water bottle, only smaller, and having a broad bottom on which it stands well. It has a moveable brass nozzle, or jet, with seven holes in it, answering to the stopper of the water bottle. The way to use the distributor is to fill the indiarubber flask about half full of the powder, using a tin funnel to prevent waste, then to replace the jet or nozzle, and on pressing the flask the powder will be forced out through the holes in a cloud of dust, which may be directed against the parts infested, and particularly the under sides of the leaves. The tobacco powder will destroy all the fly it touches and does not injure the plant. A calm day is best for dusting plants, for the wind does not blow away or divert the course of the powder, and the plants damped remain longer moist. The operation should be performed in the evening or late in the afternoon. It is not necessary for the destruction of green fly to have the plants wet, only the powder adheres better; and acting to some extent as a decoction, its effects are extended to parts not easily reached by dusting, and any danger of injury to the plant is lessened. Although the powder is not injurious to the foliage when put on whilst dry, yet when it is so applied it is well to give within six hours afterwards a slight wetting with water from a syringe. In forty-eight hours the trees or plants should have a good syringing so as to thoroughly clean the foliage. The powder is as applicable to plants in-doors as in the open air, only for plants and fruit trees under glass I consider fumiga-

tion more cleanly; but there are instances where fumigation cannot be practised, then dusting with tobacco powder will be an effectual means of freeing the plants of insects of the *aphis* family. The tobacco powder and distributor here referred to, and which I employ for freeing plants of green fly, are those of Mr. Pooley.

The tobacco powder may be employed upon trees in blossom, it does not do them the least harm, but the flowers and foliage should be dry, and a light dusting given.

Mr. Pooley has also invented a compound called tobacco soap. This is for those preferring to syringe their plants; 2 ozs. should be dissolved in a gallon of soft water, and with that strained through a hair sieve the trees or plants should be syringed, thoroughly wetting the parts infested with green fly, which the tobacco soap destroys. My experience of it is limited to trees and plants with smooth leaves, such as the Peach and Rose, and I cannot, therefore, say what its effects would be on such plants as *Pelargoniums*, *Calceolarias*, and others having soft, hairy, succulent leaves, and I may, therefore, whilst doing full justice to Mr. Pooley's invention, ask the readers of the *Journal* to exercise caution, especially as the green *aphis* is easily destroyed on such plants by fumigation with tobacco, and dusting with tobacco powder.

There is not, so far as I am aware, any means of preventing the attacks of green fly. The best natural destroyer is water. The plants cannot be too well syringed, and syringing should, therefore, be extensively practised. Some birds are great devourers of green fly. They should be protected.

Black Fly or Aphis.—This is smaller, shorter, and less common than the green *aphis*, its attacks being chiefly confined to the Cherry, hence its name, *Aphis cerasi*. It is of a bright black, and next to the blue *aphis* is the most difficult to destroy of the *aphis* family. The trees should be syringed, and dusted with tobacco powder, forcing it well under the leaves. In forty-eight hours they may be well syringed, and if any insects remain dust with tobacco powder as before. A syringing with a solution of tobacco soap, 3 ozs. to the gallon of water, will also destroy it. A decoction of tobacco, 8 ozs. to the gallon, is an effectual destroyer of this pest.

Brown Peach Aphis.—This very much resembles the black *aphis*, only its colour is dark brown; it is very troublesome on the young shoots and buds, both when the Peach and Nectarine is leafless and in foliage. The most eligible method of destruction for plants under glass is fumigation with tobacco, but it is of little use to fumigate unless the house can be filled with smoke, and it can be retained round the trees. Do not syringe the trees the following day, but keep close (without injuring the trees), and the next evening but one after the fumigation examine them, and if the insects are dead give a thorough syringing; if some are alive repeat the fumigation, syringing forcibly the following evening.

Dusting with tobacco powder will also free the trees of this pest, previously syringing them, but not so as to force off the aphides, for in that case they only find their way back again, and are out of harm's way for a time at least. For the destruction of aphides the tobacco powder must come in contact with them, for it only destroys those it touches. For destroying this *aphis* in winter, or when the trees are leafless, nothing answers so well as dressing them with a composition formed by mixing boiling water with tobacco powder until it is of the consistency of thin paint, which should be applied with a brush drawn upwards so as not to dislocate the flower buds.

Blue Plum Aphis.—This resembles the green fly, but is flatter and of a bluish hue. Of the *aphis* family it is the most difficult to destroy, for it causes the leaves to curl and fold over, thereby shielding it from outward attack. The best means is to force tobacco powder into the lodgment of the insect on the under side of the leaves and points of the shoots with a distributor, having previously made the tree wet. The following evening give a thorough syringing with a solution of soft soap at the rate of 2 ozs. to the gallon of water, or the trees may in the first instance be syringed with a solution of tobacco soap, 3 ozs. to the gallon of soft water, forcing it well into the curled portions of the leaves from their under sides, making the parts quite wet with the solution. The tree should have a good syringing with clear water in the following evening.

There are many species of *aphis* besides those named, but the preceding are the principal. All are destroyed by dusting with tobacco powder, the trees being previously wetted or dusted after a shower.

It must not be supposed that the tobacco powder will free a tree of aphides at the first application, for there may be some

of them which it does not reach, and in that case it is absurd to expect them to be destroyed, for they breed very fast. Actual contact is needed, and then one application is as effectual as half a dozen. A good look-out must, therefore, be kept, and remedial measures at once adopted, and if one application fail another must be given. There is no species of aphid that tobacco will not kill, and after using many remedies considered the most effective, I have arrived at the conclusion that they must all give way to tobacco in the form of a powder, in smoke, or as an infusion. Other remedies I have discarded, because I have prepared for me, from duty-free tobacco, a cheaper, a simpler, and a more effectual remedy.—G. ABNEY.

(To be continued.)

MELON CULTURE.

In the number for May 7th, page 346, "R. F." stated that he was perplexed as to the cause of his Melon plants in two lights losing their leaves; and having in my own practice experienced the same evil, I will endeavour to describe how it takes place, and the means by which I prevented it.

The pit in which we grow Melons is very similar to that referred to by "R. F.," save that it is heated by a brick flue instead of by hot-water pipes. In the inside wall of the hot-air chamber over which the beds are made is a slide, and on opening this hot air will pass from the chamber into the atmosphere of the pit. There are also ventilators in the roof.

Early in spring about six years ago I observed some red spider attacking the plants, which are trained on a trellis; and in order to check its progress the plants were syringed on the under side of the foliage when closing the pit at night, and having occasionally let rather too much hot air escape from the chamber while the plants were wet, I found the leaves perish in just the same way as "R. F." has described. Since that time care has always been taken to have the plants dry before closing the pit, especially on cold frosty nights, when we have to raise the temperature a little by fire heat; but at other times one of the ventilators in the roof is left open to allow of the escape of any superabundant heat and moisture. Ever since this precaution has been adopted excellent crops of Melons have been produced, the plants being clothed with large healthy clean leaves to the very roots, with not a brown spot on them.

Now these precautions, like many other valuable lessons, were derived from observing a natural occurrence: for on a certain day early in spring, about 2 P.M., a heavy snowstorm occurred, which, lasting only half an hour, was succeeded by bright sunshine; and the foliage of deciduous trees being then barely expanded, and consequently rather tender, the sudden sunshine proved too strong for some Damson trees in the open garden. The foliage on the south-western side of these was very much scalded, and next day had the very same appearance as the damaged Melon plants in the pit.—H. HALL, *Gardener to W. Dickens, Esq., Cherrington.*

WISTARIA SINENSIS.

Not remembering to have seen this glorious old climber on any but southern aspects, I fancy few people are aware how well it is adapted for northern exposures.

I have a plant about 30 feet by 30 feet on the north-east front wall of my dwelling-house, now, May 18th, about in perfection. It seems to me the colder have the following advantages over the warmer aspects for this plant. The blooming season is quite a fortnight or three weeks later, the buds are consequently not so liable to injury by frost, the flowers retain their colour, and remain very much longer in beauty, and, above all, the plant is clothed with its charming foliage at the same time with the blossom, which is not the case when it is grown on the warmer aspects.—JOHN INGRAM, *Huntingdon Nurseries.*

[We have seen the Wistaria doing well on east and west aspects.—Eds.]

THE FLOWER SERMON.—According to custom, the Rev. Dr. Whittemore will deliver a sermon on "Flowers," on the evening of Whit-Tuesday; but this year he will preach at the church of St. Catherine Cree, Leadenhall Street, and not at St. James's, Aldgate, as hitherto. The musical portion of the service will be undertaken by fifty members of the St. Paul's Special Evening Service Choir. As each member of the con-

gregation usually carries at this service a bouquet of flowers, the effect is most pleasing, and the service is rendered especially interesting.—(*City Press.*)

SPRING FLOWERS AT NUNEHAM PARK.

"AND when those flowers unfold their bloom 'may I bethere to see.'" That was a wish I expressed last November in page 405. On the 17th of April my very good friend Mr. Stewart wrote me, "Our spring garden will be in its beauty by Thursday week; can you run over and see what we are doing?" I and two friends readily obeyed the summons, reached Nuneham, and much we marvelled and admired to see the common flowers of our childhood so cherished and so prominently shown forth.

We saw in a circle sixteen large csetheons, having their fields consisting of two beds of *Alyssum saxatile* and *Arabis albidia*, two of *Silene pendula*, three of *Myosotis alba*, five of *M. sylvatica*, one of *Phlox frondosa*, one of *P. prostrata*, and two of *Cliveden Blue Pansy*, broadly and alternately bordered with *Cerastium tomentosum* and the double pink *Aucuba-leaved Daisy*. The general effect was certainly most striking. I had the pleasure of seeing these beds in a blaze of beauty last autumn when furnished with their summer bedders, and now in May they are certainly more brilliant. Eight months in flower, and for the other four the soil covered with green and variegated foliage! At the end of May Mr. Stewart will take the first safe opportunity—but there will be no hurry, for the beds are gay—to plant out his *Pelargoniums*, &c.; and then the present occupants of the beds will be divided and planted in back borders and out-of-the-way nooks and corners, or, if seed be required from any of the plants, they will be left intact and planted somewhere out of sight to mature it. I do not know if it is intended to let the *Daisy* and *Cerastium* remain for edging the beds during the summer, but they would be appropriate for the purpose; the *Daisy*, however, wherever it may be, must be kept in moist soil. Mr. Stewart informed me last autumn that he thought of dispensing with *Cerastium tomentosum*, as it would not stand the shears here; but however that may be, it looks exceedingly well and neat at the present time. I observed also that the *Roses* around were "breaking" strongly and healthily.

We now proceed to "Mason's garden," and are confronted by a group of round beds, five in number, having their centres occupied with vases on pedestals, which are surrounded with *Myosotis sylvatica* and *M. alba*, *Trentham Blue Pansy*, and the *Aucuba-leaved Daisy*. Plants of *Dielytra spectabilis*, much injured by a destructive frost, occupy the vases above. In the round Cupid bed I observed that his dart pointed to a border of *Stachys lanata*, and under the protection of his weapon were *Phlox frondosa*, *Heartsease*, and blue and white *Forget-me-nots*. Upon the greensward *Magnolia purpurea* and *Soulangeana* were in fine bloom, and *Magnolia conspicua* was about to follow. To the right, like the principal jewel in a crown, the arrangement on the site of the old orangery was in a full blaze with large scarlet *Pelargoniums* in pots, and other plants; and trained on the back trellis and in bloom was that sweet *Rose Gloire de Dijon*, ever the first to welcome us in the open air. The parallelogram beds in front of the above are occupied by ottomans of varieties of *Tulips*, having *Viola cornuta* just coming into bloom for a carpet, bordered with *Cerastium tomentosum*. I conclude the last two will be permanent, or, if not, they should be.

On passing away from here, under a magnificent weeping *Pine*, *Abies pendula*, endowed with two leaders high in the air, which must long before its natural time prove the destruction of the tree—a most unfortunate neglect—we notice on a memorial pedestal to the planner of this part of these fine grounds, the inscription—"George Simon, Earl Harcourt, Consecrates this Cenotaph to the Memory of his Friend, the Rev. William Mason."

Passing some fine clumps of *Rhododendrons* well knotted with bursting blossom buds, with *Rhododendron Cunninghamii* in full flower, and many new hybrids freshly introduced, we are once more arrested by "Mr. Harcourt's bed," in shape something resembling the letter X, with an elongated waist, which fits into a cosy nook of sward. *Liliums* and *Gladioluses* bordered with *Vinca elegantissima* are springing up in it for the summer decoration, and the present field of colour being *Myosotis sylvatica*, *M. alba*, and the *Aucuba-leaved Daisy*.

Then we wander to the north terrace garden. The effect required to be seen; no written description could depict its

beauties, and I thought it more "telling" than the more geometrical garden which we afterwards saw on the south terrace. An irregular triangle I think I may term the groundwork of this plan, and twenty-nine variously shaped or placed beds are formed to fit it. A fine standard Holly occupies a position near the eastern limb, and five handsome vases on pedestals are made to arrange themselves as symmetrically as possible in the centres of as many beds. I will give a general description of the planting; and should I fail in some instances as to truth of detail, Mr. Stewart can use a pen as well as a spade, and I hope he will be good enough to correct the mistakes. I ask my readers to conceive a few beds to be planted singly, others in pairs, and some in groups of three of the same varieties of flowers—viz., small opportune beds with Daisies and Pansies; triangular and shield-shaped beds with centres of yellow Wallflowers and of *Alyssum saxatile* bordered with *Myosotis sylvatica* and *M. alba*—remarkably striking were those beds whose fields were planted with *Alyssum saxatile* and bordered with the *Myosotis*; entire beds of the latter in *Myosotis sylvatica* and *alba*, and also of both bordered with yellow Wallflowers, and the reverse. A bed bordered with *Silene pendula*, having a carpet of *Alyssum saxatile*, was much admired. Two beds of *Polyanthus* and Blue and Yellow Cliveden Pansies, bordered with the Aucuba-leaved Daisy and *Phlox frondosa*, were long pondered over.

The vase beds had for carpeting *Aubrietia deltoidea* and Blue and Yellow Cliveden Pansies, the latter good and true to colour; but truth compels me to state that the Blue Cliveden Pansy, as I saw it here, was, with the exception of one instance, a misnomer. This one instance was where it had a position quite in the shade. In a dry position and in the sun it becomes anything but blue; but in the bed, bordered with the Aucuba-leaved Daisy, running parallel with and near to the north wing of the mansion, it was a true blue thing of beauty. The Aucuba-leaved Daisy also was more at home here; and from this spot as we stood in the shade, whilst the sun was shining upon the design, the flowers and the surrounding fresh-bursting verdure, including the play of the ground, and light and shadow, on this a really old-fashioned May day, was a sight to see and to be remembered. The *Mimulus* family takes rank along a narrow border immediately flanking the house, *Myosotis* along the east, whilst scarlet Stocks occupy the other narrow border running their length for the outsides of the plan. We then emerged on the front terrace, the groundwork of which is plain gravel. The blossoms of the fine *Wistaria sinensis*, growing against the outside of the bend of the mansion called the corridor, have fortunately withstood the frost. Mr. Stewart attributed this to the corridor being heated inside. We now arrive at the south terrace.

Plenty of enthusiasm remained even yet for the spring flowers in this symmetrical arrangement, consisting of twenty-eight beds, each nodding to another, and every flower bed having its brother. We begin with a crescent of Cliveden Blue and Yellow Pansies, then a vase on a pedestal, followed by a large bed, something in the shape of a thick-waisted hour-glass, planted with Young's Blood-red Wallflower, introduced here this season. It is a dark beauty, and is bordered with *Myosotis alba*, then follow four parallelogram beds; that to the right hand or outside occupied with *Myosotis sylvatica*, centred with *Alyssum saxatile*, longitudinally followed by another bordered with *Myosotis alba*, centred with *M. sylvatica*. The fellow beds immediately on their left are bordered with the Aucuba-leaved Daisy; one centred with La Candeur Tulip, and the other, which was lately centred with Hyacinths, was temporarily filled with new sports of Daisies. The Hyacinths I afterwards saw in the frame ground, the pots in which they were plunged being placed on their sides. I could easily judge that they had blossomed exceedingly well. Now follow two hour-glass beds crosswise, having centres filled with yellow Wallflowers, bordered individually with *Myosotis sylvatica* and *M. alba*, and so conclude the quarterings of the design. A handsome escalop vase on a pedestal is here interposed, and there is a vase to match it on the opposite side.

The only departure from a similarity of planting in the four quarters is in the parallelogram beds containing the Tulips. Opposite that containing La Candeur Tulip, Tournesol appears; opposite Tournesol in the lower quarter as we proceed is *Rex rubrorum*, and I can affirm that finer flowers of their kind were never bloomed in old England. In order to make them blossom together Mr. Stewart plants *Rex rubrorum* and Tournesol 3 inches deeper in the soil than La Candeur, otherwise the latter would appear blooming alone. *Dielytra spectabilis*,

which occupied the six vases, was severely injured by the frosts. Blue earthenware barrel seats interpose also in position along each flank of the plan, and for my part I thought they distracted the eye from the flowers. I threatened you with the arboretum when I came to Nuneham again, but again time would not allow me to visit it.—UPWARDS AND ONWARDS.

LATE BROCCOLI—DISEASED MUSHROOMS.

I HAVE forwarded to you some specimens of Cattell's Eclipse Broccoli, in order to show you the value of this variety for late spring use. The largest heads are the produce from seed sown in the third week in May of last year, the next size are from seed sown in the first week in June, and the smallest are from seed sown in the last week in June. By these successional sowings I shall be able, without difficulty, to send Broccoli to table until Cauliflowers come in from hand-lights. I know of several large gardens where Broccoli has been used up a fortnight ago, therefore in the present trying season for this class of vegetables I consider the sort I send you invaluable. I cut the same sort last year until the 20th of June.

I also enclose specimens of Fungi that came up in my Mushroom bed, spawned five weeks since. Can you tell me what they are? and are they eatable?—THOMAS RECORD, *Lillesden Gardens*.

[The Broccoli was surpassingly fine, firm, compact, and white. The specimen from seed sown in May weighed, when prepared for boiling, 3 lbs. 2 ozs., and the flower was 2 feet 2 inches in circumference. The Mushrooms are the true species, but virulently attacked and diseased by the parasitical Fungus mentioned at a meeting of the Royal Horticultural Society a few weeks ago. This parasite is believed to render the Mushroom unwholesome, if not actually poisonous.—EDS.]

CRYSTAL PALACE SHOW.—MAY 23.

THIS was the finest Exhibition without any doubt that I ever remember to have seen at the Palace, and there were some older hands than myself who endorsed my opinion by saying that it was the best ever seen there by any one. The delightful rain which at last had come to refresh the thirsty ground would have damped the hopes of an attendance in any other place; but the Palace folks are independent to a great degree of weather, the coolness of the air added greatly to the enjoyment of the Show, and the flowers greatly benefited by it. I never remember to have seen so few indifferent collections, while in some classes the plants were in advance of anything I had seen; notably was this the case in Roses and Pelargoniums.

In the class for ten Roses in pots not larger than 13 inches across, the contest was so close that it was impossible to say to which of the two collections—those of Mr. Charles Turner and Mr. W. Paul—the first prize was to be awarded, and the Judges at last cut the Gordian knot by making them both equal. Mr. Turner's collection comprised *Celine Forestier*, very fine, *Anna Alexieff*, General Jacquemint, John Hopper, *Souvenir de Malmaison*, *Souvenir d'un Ami*, Charles Lawson, Victor Verdier, *Vicomte Vigier*, and *Comtesse C. de Chabrilant*. Mr. W. Paul's were *Caroline de Sansal*, *Anna Alexieff*, General Jacquemint, *Baronne Prevost*, *Celine Forestier*, *Senateur Vaise*, *Paul Perras*, *Juno*, *Souvenir d'un Ami*, a grand plant, and *Madame Willermoz*. Messrs. Paul & Son were third with a nice collection, and Messrs. Lane & Son fourth.

In the class for twelve Roses Messrs. Paul & Son were first with beautiful plants (in my estimation plants in this class are far prettier than the larger ones), of *Alba Rosca*, *Camille Bernardin*, *Catherine Guillot*, *Souvenir d'un Ami*, *Celine Forestier*, *Mons. Noman*, *Antoine Ducher*, bearing out all I have said of it; *Madame Margottin*, beautiful; *Paul Verdier*, *Madame Willermoz*, and *Marie Baumann*, fine. Mr. Charles Turner was second with nearly equal plants of *General Jacquemint*, *Souvenir d'un Ami*, *Camille Bernardin*, *Madame Fillion*, beautiful, *Madame Margottin*, *Madame Emme Appert*, *Mille*, *Annie Wood*, beautiful, *Victor Verdier*, *Mons. Plaisance*, and *Comtesse de Chabrilant*. Mr. W. Paul was third.

Of Pelargoniums admirable collections were shown both in the amateurs' class and by growers for sale. In the former Mr. Nye, gardener to E. Foster, Esq., and Mr. Ward, gardener to F. G. Wilkins, Esq., were equal first. The former had *Marion*, *Patroness*, *Belle of the Ball*, *Royalty*, *Etna*, *Miss Burdett Connt's*, *Mille*, *Patti*, *Desdemona*, *Conqueror*, and *Garibaldi*. Mr. Ward had fine plants which resembled one very much of those of Mr. Bailey, of Shurdloes; the kinds being *Patroness*, *Sir Colin Campbell*, *Pericles*, *Celeste*, *Lilacina*, *Rose Celestial*, *Mille*, *Patti*, *Desdemona*, *Etna*, and *Empress Eugenie*. Mr. Turner and Mr. Fraser as usual ran one another very closely, the former being first with *Spotted Gem*, *Lilacina*, *Desdemona*, *Beacon*, *Pericles*, *Royal Bride*, *Rose Celestial*, *Fair Rosamond*, *Mille*, *Patti*, and *Exemple*. Mr. Fraser's plants were *Celeste*, *Empress Eugenie*, *Lilacina*, *Jewess*, *Belle of the Ball*, *Desdemona*, *Coast Guard*, curious and delicate shade of lilac; *Favourite*, *Regina Formosa*, and *Beacon*,

These gentlemen again showed in Fancies plants which were admirably bloomed, and contained the usual kinds—Countess of Craven, Acme, Roi des Fantaisies, &c. In the amateurs' class Mr. Donald was first; and Mr. Weir, gardener to Mrs. Hodgson, Hampstead, was second.

Seedling Pelargoniums in both the Zonal and Greenhouse sections were shown in considerable numbers, especially in the former. The principal exhibitors were Messrs. Downie, Laird, & Laing in the Gold and Bronze sections. They evidently have the finest strain of this class, which promises to be so effective for bedding purposes. They received first-class certificates for Magnificent, Mrs. Lewis Lloyd, Miss Maynard, Black Knight, Beauty of Kent, Stanstead Beauty, and Mrs. F. Hepper.

Messrs. F. & A. Smith showed a fine collection of their tricolor-leaved varieties, comprising Jetty Lacy, L'Empereur, Prince of Wales, Princess of Wales, Louisa Smith, &c. Mr. Mann, of Brentwood, showed his fine Zonal Lord Derby, which fully sustains its character, and along with it The Baron (Nosegay), and other varieties. Mr. Turner had some beautiful Fancies, among which were Belle of the Season, light and very bright; Leotard, in the way of Countess of Craven, but larger and brighter; Princess Teck, white with bright spots, a most profuse bloomer. These all received first-class certificates. Amongst the large-flowered varieties, Troubadour (Foster), a beautiful soft flower in the way of Emperor, received a first-class certificate. Mr. Wiggins, gardener to W. Beck, Esq., Isleworth, had Rosalind, which received a second-class certificate. Imperial (Hoyler), a fine dark flower, had a second-class certificate; and Lord Ronald, light rose, a first-class certificate. There were many other very good flowers, which will doubtless be seen in better condition as the season advances.—D., *Deal*.

Of stove and greenhouse plants in flower there was a magnificent exhibition, but as regards the kinds of plants shown not the slightest difference from former years. In point of perfection in growth, however, the specimens were for the most part all that could be desired. Mr. Peed, gardener to Mrs. Tredwell, Lower Norwood, who took the first prize in the class for sixteen, had *Aerophyllum venosum* in fine condition; a large plant of *Dracophyllum gracile*, with charming heads of white flowers; a very large Erica Cavendishii, Erica ventricosa magnifica, Eriostemon baxifolium and nerifolium, Epacris miniata splendens, Francisca confertiflora, two Azaleas, Tetratheca eriofolia, Aphelexes, Allamanda cathartica, Polygala acuminata, and Chorozema varium nanum. Mr. Donald, gardener to J. G. Barclay, Esq., Leyton, came second with another very fine collection, containing fine examples of Clerodendron Thomsoni Balfourii, Pimelea Hendersoni, Adenandra fragrans, Polygala acuminata, Stephanotis floribunda hardly sufficiently advanced, Statice imbricata, Rhychospermum jasminoides, Boronia tetrandra, Dracophyllum gracile, and very large specimens of Eriostemon linearifolium and Epacris grandiflora. Mr. Kemp, gardener to the Duke of Northumberland, Albany Park, Guildford, was third, and had among others a plant of Leschenaultia biloba major, of which the intense blue flowers were very conspicuous; the showy scarlet Erica westphalingia, and Allamanda grandiflora, not large but very fresh. Mr. G. Wheeler, gardener to Sir F. H. Goldsmid, Bart., Regent's Park, was fourth.

In the nurserymen's class for ten Mr. Williams, of Holloway, took the first position with a remarkably fine specimen of *Dracophyllum gracile*, which, measured across its curved head, could be little if at all less than 6 feet over; Clerodendron Balfourii; Ixora salicifolia, but not equal to one exhibited some years ago at the Regent's Park; Rhychospermum jasminoides, an Aphelexis, and Phorocoma prolifera, the latter not sufficiently advanced. Mrs. Glendinning & Sons, of the Chiswick Nursery, were second with very good specimens of *Aerophyllum venosum*, Pimelea spectabilis, a balloon-trained Kennedyia mophylla, Stephanotis floribunda, Heaths, Azaleas, and an Aphelexis. Mr. Baxendine was third, and Mr. Rhodes, Sydenham Park Nursery, fourth.

In the corresponding class for amateurs Mr. Peed took the first prize with a splendid specimen of Allamanda grandiflora, Azalea Coronata, a fine mass of rosy crimson flowers; *Aerophyllum venosum*, the white-flowered Erica tortuliflora, Francisca calycina with flowers nearly 4 inches in diameter, and splendid examples of Ixora coccinea and Clerodendron Balfourii. Mr. J. Wheeler, gardener to J. Philpott, Esq., Stamford Hill, Mr. Wilkie, Oak Lodge, Kensington, and Mr. Kemp, were respectively second, third, and fourth. The plants which they exhibited were mostly the same as those already named, with the exception of Coleonema rubra, Boronia serrulata, and Bougainvillea glabra, which formed a change from the ordinary run of the plants exhibited.

In the class for six plants, Mr. Ward, gardener to F. G. Wilkins, Esq., Leyton; Mr. Carr, gardener to P. L. Hinds, Esq., Byfleet; and Mr. Wilkie, took prizes in the order in which they are named; whilst equal fourth prizes were awarded to Mr. Woodward, gardener to Mrs. Torr, Ewell; and Mr. J. Wheeler, Stamford Hill. Among the plants exhibited in this class were several very good specimens of Clerodendron Balfourii, Stephanotis floribunda, Dracophyllum gracile, Genetylis tulipifera and fuchsoides, Heaths, Aphelexes, Chorozemas, and Epacris.

Of mixed collections of fine-foliaged and flowering plants, the successful exhibitors were Mr. Williams and Mr. Young, gardener to W. H. Stone, Esq., M.P., Havant, who were severally first and second;

Mr. Peed and Mr. Tanton, Epsom, to whom equal third prizes were awarded; and Mr. Gell, gardener to Mrs. Beaufoy, South Lambeth, who was fourth. Mr. Williams contributed the Variegated New Zealand Flax, with fine, boldly-striped foliage, the Variegated Aloe-leaved Yucca, a magnificent specimen of Croton angustifolium, but not so beautiful in colour as when exhibited by him last year; C. variegatum; a very large and fine Latania borbonica; Cordyline indivisa with a thick stem; and of plants in flower a fine specimen of Clerodendron Thomsoni, Rhychospermum jasminoides, and others. Mr. Young sent a broad-leaved Theophrasta, Sphaerogyne latifolia, a very fine specimen of Dracana terminalis, Cycas revoluta, a Zamia, besides, among flowering plants, a good Aerophyllum and Aphelexis. Mr. Tanton had in his collection a beautiful specimen of Allamanda grandiflora, Epacris Eclipse, in fine bloom; Pandanus elegantissimus, Dracana Cooperi, and a very fine Cyperus alternifolius variegatus; and in that from Mr. Peed, Sphaerogyne latifolia was in fine condition, besides which we noticed a very large and fine specimen of Gymnogramma chrysophylla, Crotons, and the variegated Ananassa.

Heaths were numerous shown, and many of the specimens were very fine, though in kind very nearly the same as in previous years. In the class for ten Messrs. Jackson, of Kingston, were first, and had Ventricosa coccinea minor, a fine lushy specimen in beautiful bloom; Depressa multiflora, Beaumontiana, white, tinged with blue; a large lushy plant of Cavendishii, the pretty waxy white Perspicua nana, Tricolor Wilsoni, and Candidissima. In the collection of Mr. Rhodes, who was second, were fine specimens of Ventricosa coccinea minor, Tortuliflora, Cavendishii, Esquisite, not however in a sufficiently advanced state of bloom, Profusa, and Eximia superba. Mr. Williams, who was third, also contributed some good specimens, and from Messrs. F. & A. Smith came a collection to which a fourth prize was awarded. In the amateurs' class for eight Mr. Peed sent among others fine examples of Profusa, Eximia, Perspicua nana, and Esquisite, taking the first place in the prize list, and from Mr. Ward, who was second, Candidissima and Fairrienna were both very pretty. The third and fourth prizes went to Mr. J. Wheeler and Mr. Kemp, the former showing Alberti nana, a fine buff, and in this instance so high-coloured as almost to be orange. The prizes for six plants went to Mr. Ward, Mr. Peed, Mr. G. Wheeler, and Mr. Carr, who each exhibited well-grown plants in good bloom.

Azaleas, as a whole, were not the magnificent pyramids of bloom such as Mr. Turner and Messrs. Veitch used to exhibit, and it is only such specimens that can be shown to advantage in the transept of the Crystal Palace, for the great height of the building has a dwarfing effect to the eye, making what in reality is high look small, although Mr. Wilkinson does his best to remedy this by arranging the plants as near the galleries as possible. Mrs. Glendinning & Sons had the best eight in the nurserymen's class, showing well-bloomed large plants of Murrayana, Coronata, Distinction, Iveryana, Alba lutescens, Enallie, Optima, and Extrane, the last very full of bloom; and Mr. Williams was second with a nice group of pyramidal closely-trained plants. The best eight in the amateurs' class came from Mr. Carson, gardener to W. R. G. Farmer, Esq., Chesham; Mr. Penny, gardener to H. H. Gibbs, Esq., Mr. Gell, and Mr. G. Wheeler being the other successful competitors. For six Mr. Penny was first with well-grown plants of Criterion, Napoleon, Bride of Abydos, Halford, Iveryana, and Duke of Devonshire. Mr. G. Wheeler, who was second, furnished a densely bloomed pyramid of Iveryana; Mr. Wilkie was third, and equal fourth prize were awarded to Mr. J. Wheeler and Mr. Woodward. In the nurserymen's class for six Mr. Turner and Messrs. Lane took equal first prizes. The former had Comte d'Hainaut, salmon rose; Etoile de Gand and Variegata superba worked together; Beauty of Reigate, Louise Van Baden, Madame C. Verschaffelt, Mars, and Belle Gantoise, delicate pink with a crimson blotch. Messrs. Lane sent Advance with large rose-coloured flowers with a crimson blotch, Variegata, Semiduplex maculata, Latentia, Chelsoia, and Magnificent.

Of Rhododendrons, in pots, the only exhibition came from Messrs. Lane & Son, who had a first prize for well-bloomed plants of Ernest Jones, white, with a lemon blotch; Prince Albert, chocolate maroon, Atroragineum, and several varieties with flowers of different shades of blue.

Orchids were not very numerous shown, but were so attractive to the visitors in the afternoon that it was only by dint of great patience and much maneuvering that they could be approached. Mr. Penny, who was first for twenty, had a fine example of the beautiful Odontoglossum Alexandre, O. Pescatorei, which it very closely resembles, and naviu majus, richly speckled; Oncidium sarcodes, one of the handsomest Oncids exhibited, O. crispum, Saccolabium curvifolium, Phalaenopsis grandiflora, Cypripedium barbatum superbum and villosum, Lelia cinnabarina, always very effective by its colour, especially when the specimen is fine; Calanthe vestita, Vanda tricolor superba, and others. Mr. Gedney, gardener to the Rev. W. Ellis, Hoddesdon, was second with an interesting collection, in which were the pretty Chysis Linnaeana, Vanda teres, Vanda suavis, Calanthe massee grandiflora, Cypripedium Lowii, villosum, and Stonei; a finely-coloured Cattleya citrina, C. superba, and Chysis bracteata. In the nurserymen's class for ten, Mr. Williams, who took the first prize, had Cattleya citrina with eleven flowers, fine Ardisia, Saccolabium, Odontoglossum citrosanum, and Cypripedium. Mr. Bull, who was second, had a good Trichopilia tortilis, Cattleya citrina, and Cypripedium Lowii. For twelve Orchids, Mr. Wilson, gardener to W. Marshall, Esq.,

Enfield, was first with a remarkably fine collection, in which were *Cypripedium caudatum* with fifteen flowers, and *C. villosum* with thirteen, *Lelia grandis* conspicuous by its nankeen flowers, *Dendrobium nobile*, *D. densiflorum album* with fine spikes of its white and orange flowers, *Eriopsis rubralibon*, *Odontoglossum luteo-purpureum*, and *O. citrosanum*. Mr. Young, who was second, had in his collection the brilliant orange-scarlet-flowered *Epidendrum vitellinum*, some excellent *Oncidium*s, *Arides*, and *Odontoglossum*s. Mr. Peed was third, and Mr. Burnett, gardener to W. Terry, Esq., Fulham, fourth.

New plants were shown in considerable number by Messrs. Veitch, Mr. Bull, Mr. Williams, and Mr. Wimssett, but nearly all of them have been noticed in previous reports. First-class certificates were awarded to Messrs. Veitch for *Colens Saundersii*, *Scottii*, *Batemanii*, and *Bausei*; *Alocasia Jenningsii*, *Dracena Macleanii* with very dark reddish olive leaves, *Dracena regina* with large leaves margined with pale yellow, *Dracena Moorei* and *Chelsoni*, *Retinospora filicoides*, and *Francisea calycina major*. Mr. Bull had similar awards for *Cibotium regale*, with the stem covered with brownish yellow down like a chignon, *Enecephalartos gracilis*, and *Colens Beauty*; Mr. Williams for *Cibotium spectabile*, *Zamia Ghellinckii*, and *Cocos Weddelliana*; and Mr. Wimssett for *Colens Marshallii*.

Among miscellaneous subjects, Messrs. Carter & Co. exhibited at the end of the Palace next the late tropical department a mixed collection of plants, consisting of Orchids, stove and greenhouse plants, and various subjects with ornamental foliage, including *Echeveria sanguinea* with reddish chocolate-coloured leaves, and *E. metallica* with pinkish mealy-looking foliage. The whole being very neatly arranged, formed a very attractive termination to that end of the Show. Messrs. Paul & Son contributed fine boxfuls of cut Roses; Mr. Turner a collection of Roses in pots, Azaleas, and *Lilium auratum*; Mr. Bartlett, of Hammersmith, *Hoteia japonica*, and standard *Fuchsias*; Messrs. Ponsford, Brixton, a collection of hardy Ferns; Mrs. Glendinning & Sons, excellent pans of *Anacochilis*; Messrs. Walking, Perkins, Wimssett, F. & A. Smith, Downie & Co., and Mr. Paul Variegated Zonal Pelargoniums; Messrs. Downie & Co., and Mr. Bragg, Pansy blooms; Mr. Gardener, Eaiting Park, Stratford-on-Avon, *Elrue Nectarines* and Royal George Peaches, and Mr. Schater, gardener to the Earl of Pembroke, three dishes of Cherries.

ROYAL BOTANIC SOCIETY'S SHOW.

MAY 27TH AND 28TH.

THE first Show which this Society has held during the present year opened yesterday, and will be continued to-day. It is our pleasing duty to record, that though a two-days exhibition, and, therefore, some exhibitors who would otherwise have come forward may not have done so, it fully maintains the high reputation which the Society's shows have established in former years. The great exhibition tent presents as usual a lovely scene, in which magnificent flowering plants, bold and lofty fine-foliaged plants, and graceful Ferns alternately catch the eye. Mr. Turner, of Slough, sends Azaleas, which for their size and perfection have probably never been equalled. These consist of *Illustris nova*, magnificent, scarlet; *Variegata*, Optima, Holfordi, rosy purple; *Gledanesii*, Sir Charles Napier, and *Iveryana*. From amidst the densely-set flowers which these specimens present, peep forth the light green leaves just often enough to relieve the mass of colour which the flowers present, and to enhance instead of diminishing their effect. The same exhibitor sends in a collection of smaller plants, *Duc de Nassau* and *Juliana*, the one bright rosy purple, the other a well-known scarlet, and each very fine. Mrs. Glendinning and Sons and others also send fine specimens.

The Roses furnished by Mr. Turner, Mr. W. Paul, and Messrs. Paul & Son include plants of *Anna Alexieff*, *Junio*, *Souvenir d'un Ami*, *Madame Willermoz*, *Compe d'Hebe*, and *Lonise Odier*, such as have rarely been seen before.

Of fine-foliaged plants, Mr. Fairbairn, gardener to the Duke of Northumberland, Sion, has a superb collection, in which we particularly noticed a very large specimen of the *Coccol Palm* (*Cocos nucifera*), and *Alocasia metallica* and *Anthurium acule* are remarkable for the size and fine condition of their leaves. Mr. Williams has fine collections of ornamental-foliaged plants, Ferns, flowering plants, and all these mixed, and in one of them a *Dicksonia antarctica*, which cannot be less than 8 feet in height from the ground to the top of the black trunk, at least 10 inches in diameter, from which spring its graceful fronds. The collections of stove and greenhouse plants in flower are numerous and good. Of Orchids there are several fine collections, especially one from Mr. Wilson, gardener to W. Marshall, Esq., and another from Mr. Gedney, gardener to the Rev. W. Ellis. Pelargoniums, both Show and Fancy, are excellent, and new plants are well represented in collections from Messrs. Veitch and Mr. Bull, besides which there are numerous new florists' flowers.

REPOTTING THE AURICULA EARLY.

To those who have their fresh soil ready for use my recommendation is, after the middle of July arrives lose no time in commencing repotting; get that part of the business finished before July is out. The old notion is that August is quite soon enough to repot, and in my time I have neglected and have

known others neglect potting till the end of August or beginning of September. Now that is the old system, silly as it is old, like many other bygone notions; practice and common sense teach differently. The Auricula, like many other kinds of plants, requires proper treatment at the proper time; the benefit of potting early I found out years ago, and I know other parties who have taken my advice in that matter can testify to its truthfulness. Neglect the plants till the middle and latter end of August, the old mould gets dry and finished up; the plants suffer; the fresh fibrous roots, which they ought now to be pushing, are drying off in consequence; while if planted early, while vegetation is going on, the new, fresh, and wholesome soil encourages and stimulates, as it were, new life in the plants, and while the growing season is on, they are establishing themselves, and being made fit for declining autumn and coming winter. — JOHN HERWORTH, *Huddersfield* (in *The Gardener*).

VISITS TO GARDENS PUBLIC AND PRIVATE.

MR. SAMPSON'S NURSERY, NEAR YEOVIL.

I do not know, even in the pleasantest parts of the west of England, a more pleasant-looking or prettier-situated town than the town of Yeovil. I had visited it some years ago; but being in the neighbourhood during my recent visit to Sherborne, and having heard much of the establishment of Mr. Sampson, especially in its manufacturing of bedding plants, I determined to drive over and see it; and a charming drive it was, the hilliness of the road, which made it unpleasant to the driver and the horse, making it all the more interesting for those who were driven. The town itself looks clean and thriving, and is situated on rising ground, standing up in the middle of a rich and fertile valley. Mr. Sampson's nursery is situated outside of the town at about a mile distance, while his own residence, where he has some more ground, is further off.

One is struck in visiting such establishments as these, in what one may, without giving offence, I hope, call out-of-the-way places, with the great increase in the interest in things horticultural that has taken place within the last few years; and with all the faults of the bedding-out system, great as they are, it must be credited, I think, with a good deal of this. Everybody must do a little like his neighbours—must have his or her bedding Pelargoniums, Verbenas, Calceolarias, &c.; but everybody has not the means of growing them, and hence must apply to some neighbouring establishment, and very often, indeed, to one afar off for the means of gratifying his taste. So when Mr. Sampson took this nursery there was but one house—that, indeed, a large one—while he has now several, has added a long show house for the purpose of displaying the plants when in bloom, and has myriads of bedding plants in all stages of growth and size; while in order to enable him to carry out the system he has adopted in full favour, he has secured the valuable services of Mr. Peter Drummond, one of those enterprising and clever Scotchmen to whom we owe so much in horticulture.

This long show house is arranged in a novel and effective manner. The stage on which the plants are placed is not elevated, at least not more than a foot from the ground. This platform is made of bricks, and the interior filled in with gravel, &c. The plants stand on this, are thus kept cool, and are below the level of the eye, and the whole mass of verdure and flowers can thus be seen without any interruption. Azaleas, Camellias, and Cinerarias at the time of my visit had just gone out of bloom, and Calceolarias, Pelargoniums, &c., were just coming in in full force, and would soon make the house lively; but the bedding-out plants formed the chief feature of the establishment, and to them mainly the old house was allotted, while in a new propagating house their manufacture was still going on. All the newest and best varieties of the various plants used were here to be seen. Immense numbers of Mrs. Pollock made one end of the house gay, and Verbenas of the best and most approved kinds were to be seen in thousands. Mr. Sampson also possesses a very excellent bedding Lobelia, which for size and sturdiness of growth is far superior to any that I have seen, although I have not seen the new Lobelias of this year, about which so much is said—viz., *Trentham Blue*, &c. Like most of our growers, Mr. Sampson has something to say to variegated Pelargoniums, grows all the best of the tricolor kinds, and is essaying something in the seedling way himself, especially in the gold and bronze section.

Among the noticeable plants in the houses were three or

four of the largest specimens of *Cereus truncatus* that I have ever seen, and every season these magnificent plants show hundreds of blooms, and are a perfect sheet of flower. They have been offered, I believe, by Mr. Sampson to H.R.H. the Prince of Wales for Sandringham. They would not be out of place in the finest collection in the kingdom.

The out-door department displays the same vigour and

energy that characterised the in-door department, and although not extensive, was well arranged. Roses are in some degree attended to, and will ultimately have a larger share of Mr. Sampson's attention. My visit was necessarily a very hurried one, and not at the best time to see an establishment like this. Later in the season I may hope to see it again.—D., Deal.

ROSE-BUDDING IN JUNE.

Being a great lover of Roses, and knowing that the pages of your Journal are scanned by many thousands of those who also delight in cultivating this lovely flower, I send you a short account of a method of budding in June which I have invariably found successful.

In October I select and plant what stocks I require, and when in the spring they commence growing I pinch or rub off all the shoots except two, three, or four, according to the strength of the stock; those remaining I allow to grow to their utmost extent.

I ascertain the time they are ready for budding by rubbing off some of the thorns, and if these are easily detached I know the stocks are in the right condition. I then cut the shoots back, leaving on them three or four buds to the stock. In the

shoot to be budded I make a T cut (as shown in *fig. 1* at *a*), just through the bark, being careful not to injure either the wood or bark, insert the point of the handle of the budding knife gently into and along each side of the longitudinal cut (*fig. 1*), detaching the bark from the wood to allow of the insertion of the bud, for which it is now ready. Obtain the bud by choosing one which appears to be the fullest from a branch or shoot of the Rose to be propagated. Cut it off, as shown in *fig. 2*, take the wood out of it carefully, so as not to pull out the heart of the bud, insert it in the T cut under the bark, *fig. 3* (in *fig. 4* I have shown a large bud with the wood in *a*, the wood in course of removal at *a'*, the wood taken out, the heart of the bud being left, and to which the arrow points, at *a''*), push it close up, as in *fig. 5*, and tie firmly with wool

or ball lamp cotton, as in *fig. 6*. As the original buds in the shoots in which the bud of the required Rose has been inserted keep pushing I pinch them all off, in order to throw as much vigour as possible into the inserted bud, and am careful that no other shoots grow from the stock. When the inserted buds have grown the length shown in *fig. 7* I remove the tie. As I prefer to have blooms as soon as possible, I permit the inserted bud to grow as long as it will, and am often rewarded with flowers the same season. In the following April I cut back

this shoot, leaving only on it three or four good buds, as shown in *fig. 8*.

As many amateurs may not be aware of the foregoing plan, I have been induced to send you such an explanation of it as I trust will enable them to try it for themselves, and thus "steal a march," or rather a season, on their trees. Floriculturists are, I am aware, too busy at the indicated time, but this is not written for experts, but beginners.—T. J. S., Twickenham.

WORK FOR THE WEEK.

KITCHEN GARDEN.

KEEP this department free from weeds; one good weeding is better than three hoeings and rakings. Indeed, except for covering seeds or gathering off stones, the rake should not be much used in the kitchen garden. *Asparagus* will be much improved if the beds do not become dry till the berries begin to change colour in the autumn. *Lucks* are a very useful vegetable in winter, and this is about the best time to plant them out from the seed beds. *Onions* are often injured by being left too long in the seed bed, or too close together in the rows. Thin, sow, and plant succession crops as their different states indicate.

FRUIT GARDEN.

You cannot pay too much attention to thinning, stopping, and training the summer growths of fruit trees. Fig trees should have the points of the shoots that are rampant pinched out. This will cause the young fruit to swell better, and will have a tendency to render the shoots more fruitful. In making a fresh plantation, secure a dry situation, and keep the plant growing from one stem, as the sucker-like appearance which Fig trees generally present is a great drawback to their proper management. Vines in favourable situations should have the fruitful shoots shortened to an eye beyond the bunch, and these shoots so thinned that the Vines will be able to perfect the bunches.

FLOWER GARDEN.

All the China, Tea-scented, and Bourbon Roses that have been forced since last Christmas will now be on the decline, and should be well pruned back, and all the weaker shoots cut out entirely. There are many of them so free-blooming as to continue in flower for months, but it would be bad management to let them do so, as there will be no want of Roses for the next six weeks. If these plants were now repotted, shaking away the greater portion of the soil from their roots, and placed in a shady situation for about two months, pinching out what flower buds they make during that time, they would be in a fine condition for autumn use in the conservatory. Large plants of Sweet Briars that have also been forced throughout the winter, should now be entirely cut down to the surface of the pots and set in a shaded place. It will not answer to prune Briars that have been forced, like other Roses. They become so hard in the wood by being constantly deprived of their foliage, that nothing short of cutting down will bring them about again, but by this system the same plants will do for years and answer better than young ones. The very gayest bed on the lawn in autumn might be made by the following high-coloured Roses, which are of nearly the same tints of scarlet and crimson. Suppose the bed to be a circle, place *Gloire de Rosomone* in the centre, and tie it up to a stake, it being of a half-climbing nature; then a circle of *Cramoisie éblouissante* and *Cramoisie supérieure*, then *Henry V.* and *Saint Pierre*; the next circle of *Fabvier*, and the last, next to the grass, of *Psyche*, which is a Bourbon, but differs little from the rest in foliage. This is about the time to plant these out, and any Rose-grower can furnish a large bed of them for a few shillings, as they are all cheap varieties; indeed, their cheapness and their high colours are the reason for pointing them out. As we are at length likely to have a good soaking rain, it will not be necessary this week to do more than direct attention to former calendars, and urge the necessity of bringing the work up as soon as possible. Where the grass on lawns is much burned by the hot weather, it will assist it much in recovering its verdant hue to dress either with liquid manure, or some artificial manure considerably mixed with light sandy soil. A little lawn Grass and Dutch Clover seed thrown on previously to covering with soil will do much good, especially on spring-laid turf where soil to fill up the cracks is indispensable. Mow, roll, and sweep lawns and walks, and keep every thing and every place as clean as possible. Annuals may now be advantageously thinned, and the thinnings if not too large may be used for filling up gaps in the borders. Seedling *Auriculas* must be shaded from the glare of the midday sun, and especially watch the attacks of green fly, which usually secretes itself in the heart of the plant, and multiplies very fast in hot weather. Remove the insects as they appear. Place two or three flat oyster shells on the surface of the soil in the large pots; it prevents evaporation, and also saves the roots from being washed bare in watering them. *Polyanthuses* are very subject to the attacks of red spider; to keep these pests down shade the plants, and if in a bed keep the soil moist around them. Break off the capsules of *Tulips* to

strengthen the roots. The bulbs on the offset beds will soon be ready to take up should dry weather set in. Use every means before recommended to keep your *Carnations* and *Picotees* free from green fly. If the insects become numerous the bloom will suffer severely. Tie-up diligently and top-dress with some very rotten manure. Pinks do not appear so liable to the attacks of the green fly as the before-mentioned flowers. Water seedlings, and pull up those which are single or have serrated leaves. They are not only worthless, but their removal will benefit those which remain. Continue to put in cuttings of *Pansies*. Those slipped nearest the root succeed best, the thinner they are the better; strong shoots seldom make good plants. The stakes ought to be put to *Dahlias* without delay, and the plants will be better of a mulching of rotten manure.

GREENHOUSE AND CONSERVATORY.

New conservatories, where a collection of climbers has been planted this spring, should now be kept as hot as a stove, and as damp as water can make them day and night; it is bad policy to use the common routine for such a house the first season. We often hear of large conservatories becoming too hot and injuring the plants in summer, but it is the want of moisture in the atmosphere and not the heat which causes the mischief. All spare places and under the stages in any conservatory should now scarcely ever be dry. Plants in flower here must be constantly shaded while the sun is strong upon the glass. Ladies when viewing the large *Pelargoniums* at the metropolitan shows are often heard to say how much they would like to have some of their own plants trained in the same way. Nothing is easier if there are plenty of plants of each sort to be so trained. When the plants are just coming into flower put four or five of them into one large pot, keeping the best side of the plants outwards, and with a little training a specimen of any ordinary size can be made at once; and if the soil is good the plants will flower in this way much longer. Keep the greenhouse moist by frequent syringing; turn the plants round from time to time, that they may not become one-sided; and allow them to have plenty of room on all sides, which is the grand secret in growing these plants to perfection. The flower buds of such young plants as are intended to become specimens ought to be picked off in order to encourage their growth. There is nothing more general or more difficult to manage than attempts at growing and flowering these plants in the same house; but then they cannot by any possibility be grown to anything like perfection. House plants in our climate must have large portions of water thrown over or amongst them, to keep up a moist atmosphere while they are growing, and flowers will not stand this with impunity.

STOVE.

Clerodendrons, *Vineas*, and other stove plants intended to flower in the conservatory through the summer should now be removed to the coldest part of the house. There is hardly a stove plant which may not be thus inured in summer to flower in the conservatory. Most of the *Orchids* are well suited for this purpose, and as few ladies can endure the close heat of the stoves, unless the inmates of these houses are so managed their beauty is in a great measure lost.—W. KEANE.

DOINGS OF THE LAST WEEK.

We continued in the daily expectation of rain, which did not come until Friday and Saturday, when we were quite prepared for it. We well cleaned a second tank in good time, and should have been vexed if the pure soft rains had become mixed with what had remained for the greater part of eighteen months, with frequent additions from every shower. In the very dry days of the first part of the week, ending on the 23rd inst., two things struck our attention—first, the boldness with which all crops that had been surface-stirred or mulched met the heat and drought; and, secondly, the rapidity with which *Lettuces*, *Cabbages*, *Cauliflowers*, &c., grew in the latter warmer days of the week, when not assisted at all in the way of watering. The genial warmth made all the difference, the warm nights as well as the warm days. The sun was quite as hot in the earlier days of the week, but the air was drier, and more parching, and the nights much colder. All our smaller crops, as *Onions*, *Carrots*, *Farnips*, &c., had a good hoeing with the Dutch hoe, so as to leave the surface loose and clean.

Box Edging.—We shall not yet be able to do anything to ours, but from this to the middle of June is a good time for cutting it in rather freely, when that work is done only once in the season. After this time there will be little risk of frost

blackening the young growth, and the lines will look tolerably neat for the year; but, of course, not so well as those nipped several times in the season. Box will always have its admirers, just as anything that grows is to many more interesting than the inert thing that is made; but tiles and even slate make very neat edgings, and, requiring no annual labour to keep them right, they are ultimately much more economical than Box, and afford nothing like the same refuge and hiding place for vermin. Young straight Box edgings are best clipped square on the top, then a line strained tight in the centre, and the sides cut square or pointed to it. Edgings which are stronger and better established are often cut with the scythe. A good workman who can command alike a firm wrist and a good eye, will leave work behind him that would rival that of the best clipper, and with much less labour.

Sea-kale.—That which we planted out suffered from the dryness, and the best plants with bold and good crowns suffered much more than those set, which consisted merely of bits of roots with no perceptible bud, being merely pieces of the ends of roots from 4 to 6 or 7 inches in length. These, planted with merely the upper end about level with the surface, have thrown out several buds, green and flourishing, whilst many of the good plants with prominent buds do not look so flourishing as when put out, and will require this rain or a watering to give them their due advantage. In the case of the plants, they were growing a little before being planted, and the transplanting gave them a check, which we ought to have counteracted by two or three waterings in the dry weather, but these we could ill afford to give. The pieces of roots without visible buds had nothing to do but secure the moisture in the earth to preserve their vitality, and hence the warm weather, when it caused the latent buds near the surface to break, induced also the lower part to put out fibres to keep up a supply of sap to the expanding buds. This affords a proof that it is often best to move plants and trees when in a state of comparative repose, and that when moved in a growing state there should be as little check as possible involved in the moving. Had we done justice to these plants with buds, they would have been as much before these pieces of roots now as we have no doubt they will be a few weeks hence.

As the cutting season is now over, all the plants should be dressed and cleared gradually of their flower heads, except the plants intended to be left for bearing seed, and these should not be forced next season. We use the word gradually intentionally, as these flower heads make a delightful vegetable cooked in the usual way, and thus afford a change for a week or two. When this use is not approved of, then the heads may be cut off, and taken to the rubbish heap at once. Our Cauli-flowers are coming in nicely, but in the occasional break between them and Broccoli a basketful of Sea-kale flower-heads makes a good change at the hall table at least; and we have heard the most refined gentlemen speak highly of the dish, just boiled as a woman in a cottage would do, using boiling soft water, and a pinch of soda in the water.

One fact more. Against the convictions of our experience we planted out a number of the roots we had taken up to force first. These, however plump and fresh they look, seldom do well when planted out again. A good many thus treated have rotted away. In the dryness we would not have been surprised if they had shrivelled up a little, but they rotted. Now the plants thus taken up for forcing are useless afterwards in proportion to the earliness and the crops taken from them. Plants that yield later gatherings in spring, and are cut only once, do not suffer in the same way from being taken up. There is a simple way in which we can be independent of all such early-forced plants, even if we do not give ourselves the trouble to raise plants from seed, and there is generally a little trouble involved in this, first from rats, &c., purloining the seed, and then from birds and turnip fly making inroads among the young seedlings. In taking up plants to force in mild hot-beds, Mushroom beds, &c., the size of the head or top when we cut it for table will generally be in proportion to the thickness of the root, and the prominence and size of the bud or buds at its point, and but little in proportion to the length of the root. These tuber-like roots may be dug up with their rootlets to a length of from 12 to 18 or more inches, but we have always found that 6 or 8 inches in pots or beds just yielded as good gatherings as if the roots were double the length; nay, though we would not at present recommend the practice, yet we have found large roots of 3 and 4 inches in length yielded as good produce in such circumstances as longer ones. Supposing you took for forcing roots of from 6 to 10 inches in length, what a

quantity of the smaller roots, and even larger ones from a quarter to half an inch in diameter, would thus be cut off; and each of these cut into 6 or 8-inch lengths, and laid thickly along the ground in a trench, with the points out, and a little short litter over them during the winter, would be just suitable to plant out in well-prepared ground next spring, and the strongest might be forced in the first winter, and the weakest in the second. We are the more particular on this matter, because we know there are so many who consider Sea-kale to be a desirable luxury, but think that it is beyond their means, and we wish to show that any one may have it who can devote a few rods of the garden to grow it in summer, and that without mounds of fermenting dung in the garden in the winter.

Vegetable Marrows and Ridge Cucumbers.—Filled the trench and replaced the earth as alluded to lately, and the soil having become so warm by being exposed when dug out, we set some hand-lights on and planted at once, contrary to our general custom in such cases, which is to wait until the earth is warmed. In warm places there is little necessity for this care, but the old plan of producing a little heat below the ridge is good, and the heat can be easily supplied where there are stumps of winter stuff to be disposed of, a little long litter to be had, and mowings from the lawn to mingle with it. The litter neutralises and retains the heat from the grass, which otherwise would be too violent and evanescent.

Cucumbers.—Moved cuttings, seedlings, &c., from a couple of two-light frames over a mild hotbed, formed much as above stated, forked over the upper and sweetest portion of the bed, added a ridge of littersy manure and leaves all round so as to elevate the frame when put on, leaving a trench in the centre for the soil, and as that soil had been exposed to the sun of the previous hot days and well warmed, we turned out the strong plants at once, as the produce may be desirable, and we can dispense sooner with the early bed if we like. That two-light bed has borne wonderfully and almost exhausted itself, but on cutting most of the fruit, removing the older leaves, and giving it comparative rest for eight days, it is now breaking afresh with vigorous fruitful shoots.

Melons.—What we have said above about warmed soil, we would have put in operation with Melons in cold pits, but in one case we wanted the room for Beans, which we wished to turn out of a vinery, and in the other we could not raise at the time the bedding plants growing in the soil. The practice we intended following, and which we have followed successfully years ago, we may mention for the benefit of those who have a pit or frame that will now be emptied of the bedding plants, and who have no dung heap to afford the means for obtaining artificial heat beneath the soil for Melons. In such a May as this success would have been certain. We used to get the soil in the place fresh and rather stiff and not at all fine, and just a little rotten dung or leaf mould in it. This when it had remained for a day or two with the glasses shut, and exposed to the sun, would be turned over, and the operation repeated several times until the soil was well warmed throughout, the warming being accelerated by covering up the glass at night. With such treatment, and husbanding sun heat, Melon plants turned out in the end of May and the beginning of June with no artificial heat, yielded good returns early in autumn. We have planted out strong plants over slight hotbeds because we had the chance to do so, and in a dull season they will be more sure than if they had no artificial heat.

FRUIT GARDEN.

The rains will beat all our watering as respects Strawberries, and, in fact, these were tolerably well before the rains came, except the Black Prince, which showed signs of a little suffering, and which hitherto has been much valued for jam and other preserving purposes. We hope to litter a good many of our borders and quarters on Monday, and thus keep the moisture in and the fruit clean. A considerable amount of trouble is now requisite to keep up a good regular supply of Strawberries from under glass. We do not expect much from the open ground for three weeks. The earliest-forced ones planted out are beginning to show the flower buds, and will come in useful when the general crop is gone.

Orchard House.—Removed the earliest Peas, and the second and third will follow ere long, as the first-transplanted ones of the taller kinds out of doors are now coming in. Had the houses emptied of most of the flowering plants that stood beneath the trees in pots; and as these pots wanted much watering during the last three weeks, the mulching has almost disappeared, and must be replenished if possible next week. It is of no consequence if this mulching of rotten dung, &c., is

placed considerably above the rim of the pot if two things be insisted on, otherwise there will be risk of danger. First, in watering, the waterer must avoid jetting the water into what would soon be a hole close to the stem of the plant—a practice which, besides having a tendency to leave the outside soil unwetted, has ruined more tender plants than perhaps any other bad practice. The petting-high of hair-rooted plants might never have been so general if the waterer would have kept water from dashing against the stem, or rather collar of the plant. In the case of these mulched orchard trees let the water be poured over the whole of the surface, and more particularly be directed to the circumference rather than to the centre. Secondly, never be satisfied with the mere surface appearance, or even ringing the pots if partly plunged, but examine, with a finger or the point of a stick, a few inches below the mulching; otherwise you may have a moist surface and great dryness of the roots an inch or two beneath the surface. When used to it you can tell when a plant is in danger from this cause as you pass along; but until that aptitude is learned from observation there must be no disdaining to examine the state of the soil, which is better in every way than an indiscriminate pouring from the water pail. The mulching lessens the frequency of watering, and prevents hardening the surface soil too much, but it likewise conceals defects as to too much or too little moisture that can scarcely be found at first without such particular manual examination.

In other houses the work was much the same as in the previous week. We keep the late vinery warmer now, as the Grapes are coming into bloom. In a week or so we will keep the first orchard house closer and shut up sooner for the same purpose.

ORNAMENTAL DEPARTMENT.

Our work here has been heavy, consisting of rolling, mowing, clearing the lawn of Daisies with the knife, and digging and preparing beds and borders for planting. We remember the 22nd of May last year, and how we escaped by a little patience. The rain will cause the ground to work beautifully, and most likely we will turn a good many plants out next week before this is read. To beginners we may say, if we have much rain and the soil is at all heavy and stiff, avoid planting out when the surface soil is wet and claggy. If you do, you will repent it during the season. It will be months before such claggy soil becomes kindly. It is in every way better to wait until the surface has become rather dry. Of course our advice does not apply to small beds, where one can plant without even setting a foot on the bed. We know that the advice in many quarters is "Choose a rainy day to plant in." We say, on the contrary, On all stiff heavy soil that will run together when pressed wet, and not be easily disintegrated when dried, plant when the surface is rather dry, either before rain is expected or after it has come. In such a condition of the soil the work can be better, more quickly, and more comfortably performed.

Our second golden rule would be, Give time and care to the planting. When we did much more flower gardening than now, we one year could have boasted how very quickly we turned the whole out. We would never wish to have the power to make such a beast again. Of course, in rain or in sunshine a slit for a plant is soon made, the roots slipped in and the earth squeezed against them. It will be generally true economy to make first a hole or a trench, and give the roots full justice in having well-pulverised soil around them, without leaving the mark of a foot on the ground.

Our third rule would be, Water to moisten just a little beyond the roots, resurface with the drier soil, and avoid surface-watering, unless in some great emergency. The first watering will serve the plant for a considerable time; and if it shows a little distress, and you are sure there is moisture enough at the roots, give it a little help by shading, or wetting the foliage, merely to arrest a rapid perspiration—too rapid for the roots in their new quarters at once to meet.

American Plants.—In answer to "PUZZLED," who has a bed of Azaleas that looks as if dry, and which no watering seems to improve, Try what mulching will do; but before being satisfied with that raise a plant or two, and examine the ball carefully, as for orchard-house trees in pots. We once helped to make a valuable bed all right that seemed going beyond hope of recovery. The plants had been turned out of large pots into a bed of heath soil and sandy fibrous loam. On examination at the roots it was found that the plants had been turned out of pots with the balls dry, and all the barrels of water lavished on the bed had passed the balls like raindrops from the wing of a duck. The plants were lifted, their balls put standing in a tub of water for ten minutes after any air-bell had ceased to appear;

they were then replanted, and bloomed and grew beautifully the same season, and, as far as we know, ever afterwards. In raised beds, even established plants can scarcely have enough of moisture without mulching.—R. F.

COVENT GARDEN MARKET.—MAY 27.

A STEADY supply and a rather better demand for superior goods have been experienced during the past week. Strawberries from the open air in the western counties are now plentiful, there have also been large consignments from France with the other usual produce. Good early Peas from Kent and elsewhere are now in, as are also early Ash-leaf Potatoes.

TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

JOURNAL OF HORTICULTURE PRIZES (An Intending Exhibitor).—The first considerations with the Judges in awarding our prizes at the Royal Horticultural Society's Exhibition at Leicester, on the 16th of July next, will be the excellence of the fruits and the taste with which they are arranged. The exhibitors must find their own dishes. Seven dishes of fruit better grown and better arranged would be entitled to a prize in preference to any larger number deficient in these qualifications. There are no stipulations as to "points." The Judges will award the prizes to the collections which in their opinion are of the fruits best cultivated and most tastefully set upon the table.

LEICESTER SHOW (W. Williams).—Apply to Mr. Eyles, Royal Horticultural Society, South Kensington, London, W., and he will furnish you with every information.

PETERBOROUGH EXHIBITION (Harry Porter).—The wording of the schedule is so indefinite as to the classes you mention, that we cannot advise you. You had better consult the Committee.

FOWLS' DUNG AS A MANURE FOR ROSES (A Subscriber).—"You are in error in supposing that chickens' dung, old or new, solid or liquid, on the surface or next to the roots, killed your Roses. Roses planted this spring, if not properly planted and carefully attended to, and watered both over the foliage and roots, would probably die or suffer greatly. Fresh cow dung, solid or liquified, is admirable for almost all kinds of plants, especially for Hollyhocks and Dahlias. It is cool, does not contain much uric acid, and I never knew it injure anything to which it was applied. You had better mulch your freshly-planted Roses, kill the aphides, cut off the leaves spotted with orange and other fungus, thin out leaves where they are tangled, syringe the trees well, and apply water copiously to the roots. Honeydew is more abundant than I ever knew it before; it is a viscid secretion from the tree, of which insects are fond, but of which they are not the cause. It must be washed off, as it stops the pores of the leaves. Roses open here abnormally with green centres. Take them off at once.—W. F. RADCLIFFE, *Oxford Fitzpaine.*" A liquid manure made of 1 lb. of fowls' dung to each gallon of water would be the proportions we should employ, and give it once a week; and the same might be applied to ordinary bedding plants and culinary vegetables; for the latter 2 lbs. to the gallon would not be too much.

BLIGHTED ROSE TREES (C. D., Godalming).—"As far as I can judge of the smashed leaves sent, the blight appears to be mildew—white fungus. If you have only a few plants so affected you may on the first appearance rub it off with your finger and thumb. Some Rose-growers use sulphur

of the two kinds, black sulphur is the better. I use for Roses 2 ozs. of blue vitriol dissolved in hot water and then mixed with a stable bucketful of cold water. I know not how it may act on the leaves of other plants. When a tree is hopelessly mildewed I cut off the branches and leaves. I have thus treated a second time this season a tree of *Triomphe de Reines*, 12 feet high. With regard to inducing the seedling Hybrid Perpetual to bloom, do not attempt it if the plant is weak. If it is strong take off the points of the shoots and side branches. W. F. RADCLIFFE."

GRAPE *Nottinghamensis*.—The Muscat Eschodra is the same as White Muscat of Alexandria. We consider Schiras a very excellent early Grape. Is yours the true one? We cannot discern what look your third question refers to.

PEARS DESTROYED BY INSECTS. (W. S.)—The beetle-like insect which destroys your orchard-house Pears by eating through their stalks, is the *Cureulio macularis*, or Spotted Weevil. It conceals itself in the soil during the day, and feeds at night. Your best remedy is to shake each tree over a white sheet at night, and destroy the insects which fall upon it. If this be repeated on two or three successive nights you will exterminate the marauders.

EARLY PEA.—Mr. G. Edgerton, Strawberry Hill, has enclosed us (May 20th) some pods of Dickson's First and Best early Pea, and says he finds it about a week earlier than Sangster's No. 1, and several other varieties, sown January 20th in pots, and planted out on the first favourable opportunity.

WIREWORMS (*Agelias*).—We do not know of anything that will destroy wireworms without causing injury to the crop. If, when you sow Peas, &c., you were to give a good dressing of soil, and were to point it in where the rows are to be, it would in a great measure drive the wireworms away from the Peas. You might also make a number of holes along the sides of the rows of Peas, drop into each a potato, and cover it with soil. These may be examined twice or thrice a week, and the wireworms destroyed. It is well to thrust a stick through each potato, for it will serve both as a mark and a handle by which to pull the bunts up for examination.

CALANTHE VESTITA (S.).—The young growths of the present year will form the silvery bulbs of next year, and from their base will proceed flowers this or next year if they be properly nurtured. The present silvery bulbs will die away after they have flowered, or when new growths have been produced by them; but they may not die for some time after the new bulbs are formed. It is not likely they will flower in autumn, or that new growths will proceed from them next season. It is quite unusual.

CELOGYNE CRISTATA WEAKLY (*Idem*).—We think your plant is weak, and that last year's growth was very poor; but according to your description it is progressing favourably, and will, with encouragement, produce a better growth and bulb this season.

DENDROBIUM NOBILE LEAVES BROWN (*Idem*).—The leaves turn brown and rapidly decay from their being kept in too cool an atmosphere, and from being too much watered over. Give more heat and maintain a moist atmosphere, avoiding the wetting of the leaves to such an extent as to cause water to hang upon them.

PLUMS NOT SWELLING (K. K.).—We can only suppose that your tree has suffered like many others from frost, and that we believe has been the cause of the fruit falling shortly after setting. We have not a heavy crop on our standard, bush, and pyramid trees, although they gave great promise. On trees against walls we have a splendid crop of Plums, and the fruit is larger than we remember to have seen it in May.

BUDDING PLUM TREES (T. T. S.).—Plum trees are best budded; indeed, grafting Plums is not general. The best time to bud is as soon after the middle of June as the bark parts readily from the wood. All budding is done in the same manner as for the Rose, only Plums are budded about 6 inches from the ground and on the side of the main stem.

BUDDING ROSES (*Old Subscriber, Ireland*).—There is no pamphlet on Rose budding, but you will find full particulars in Rivers's "Rose Amateur's Guide," published by the Messrs. Longman. Thomson's styptic is not necessary for budding Roses, but it may be used for the purpose, and is thought by some to be an advantageous application. It may be procured of any seedsman.

THINNING NECTARINES (D. W.).—You should reduce the five hundred Nectarines on a tree 15 feet by 6 feet, to half that number; but if your tree is not very vigorous, we would not have more than two Nectarines per square foot, or 150, and if weak we would reduce the number to 150.

CROP FOR A VINE (*Idem*).—Your Vine with three rods will certainly bring to maturity twenty-four bunches, better than a Vine with the same number of bunches on a single rod; but you must bear in mind that the size of the bunches has much to do with the quantity that may be left on a Vine. If you have large bunches on the Vine with three rods, then you must not expect them to arrive at the same degree of perfection as if less bunches were on the Vine with a single rod. If you have large bunches you must allow fewer of them to remain than were the bunches smaller, for a Vine with but eight bunches may give a greater weight of Grapes than one with twenty-four bunches upon it.

BOILERS (*Imitator*).—Your boiler may be a very good one. One characteristic we contend for is simplicity, and we are also of opinion that the setting and the management are more important than the mere form of the boiler. Most boilers that need no brickwork, unless supplied with an air-tight jacket, waste heat much more than if set in brickwork, for what is absorbed by the brickwork will be radiated back again. Boilers without brickwork are chiefly useful in small places, and where moving the boiler and all appurtenances is a matter for consideration. A large boiler on that principle we do not look upon as economical so far as heating is concerned. (*Anxious Inquirer*).—We think that water tubes are not so good for firebricks as iron bars where inferior fuel is used. Your obtaining so high a temperature so easily at one time, and the difficulty of getting the water warm at another time, show that there is something different in the management. If one course of management will so easily heat the water, we can see no reason why that should not be done again if the same draught is secured, and most furnaces require cleaning out, to clear out clinkers, &c. By the management of the furnace bars, a brisk or a slow combustion can be obtained. In the one case keep them open for air, in the other keep them comparatively close to exclude much air. We prefer a little small coal to mix with coke in lighting, and the

little extra smoke is counterbalanced by the quickness of ignition. If this is not allowed small broken coke should be kept on purpose for lighting. If you become fireman because your young men cannot manage the fires, there will soon be something else they cannot do.

CUTTINGS OF GOLDEN CHAIN PELARGONIUM (C. P.).—There are two periods for striking Golden Chain first, in July and August, in sandy soil in the open air; and in February, March, and onwards, in a hotbed. We cannot say why your *Musros* mis after showing do not grow, but we would reduce the temperature of the house to from 50 to 60, seldom above 55, and see that the soil do not want for requisite moisture.

ROSE TREE WITH PENDULOUS BRANCHES (P. S.).—No Rose except a drooping or weeping one will long endure having the principal branches drooping down. If you have not irretrievably injured the *Solfaterre* Rose, pruning it and allowing the shoots to grow upwards, or at least not below the horizontal, will give it a chance of recovery. If you wish to cover to the pot with such a Rose, you must not have a standard, but shoots as low as the rim of the pot.

FLOWER BEDS (*Jackman*).—We neither exactly know what you aim at, nor the position of the beds. The following would look well in the beds, each 10 feet in diameter, and each having four bands and a centre—thus, first bed, 1st row, Venus's Looking-glass and Virginian Stock; 2, *Silene pendula*; 3, Yellow Hawkweed; 4, Blue Branching Larkspur; 5, Prince's Feather. Second bed—1, Yellow Heart-ease; 2, Blue Nemophila; 3, White Candytuft; 4, Lobel's Catchfly; 5, *Delphinium formosum*. Third bed—1, Purple and blue Heart-ease; 2, Tom Thumb Yellow Tropaeolum; 3, Purple Jacobaea; 4, White and Blue Branching Larkspur; 5, Lobel's bleeding.

PEACHES FALLING (*Old Subscriber*).—Want of ripeness of wood, owing to the strong growth, is, no doubt, one of the reasons why your fruit buds fall and do not set. Try what less watering will do; if that do not give firmer wood, and root-pruning in winter is so ineffectual, try lifting and replanting the trees in the first days of October. We do not like such root-pruning in summer, but we have done a little to over-vigorous trees with advantage. See "Doings of the Last Week" of May 21st, on thinning buds, &c. Watering with guano, or with lime and soot water, will scald the ants from your houses. Sugar and arsenic mixed together in a saucer, and a saucer put over it, with a thin slip of wood between the two, to leave room for the ants and for nothing larger to enter, will soon put an end to those which partake of such a dainty.

PEACHES, &c., IN ORCHARD HOUSE (W. H. Doughty).—See the previous reply, and we also refer you to "Doings of the Last Week" in last week's Journal as to thinning buds and fruit. We think two circumstances are against you—the smoke of the town to which you are so near, and the using old kitchen garden soil for your orchard house, especially after so well securing drainage, &c. Meanwhile we do not see anything wrong in the colour of the foliage, and a little soot water would help to make it darker. As the trees grow so well and strongly they cannot be much hurt by the soil, though we would prefer it fresher, but our own trees are just in the old border. However, as the bushes do best, it shows the soil is not so much at fault as free growth, and if these pyramids were ours, and we could not ripen them, we would lift and replant in October. The size of the wood does not look as if they were too luxuriant, and it strikes us that your soil may be rather dry in winter and spring before the bloom opens. Try what a little more moisture will do. The specimen shoot of *Nectarine* sent seemed to indicate that the fruit had too much exposure to the full sun, and the small fruit showed the tree was also making a selection for itself. Try a thinning early in spring of the buds that cluster thickly; but above all, see that the soil is moderately moist before the buds begin to swell; and to hasten the maturation of the wood give little water, and a dryish atmosphere after you gather the fruit.

GRUB, &c. (*Answer*).—How to get rid of the "grub" that is eating up your *Cerastium* plants, is a question difficult to answer, not knowing what insect your mean by "grub." If it is the larva of the cockchafer that has eaten up the roots below the surface, then we can advise no better plan than to take the *Cerastium* up, examine every bit carefully to see that there is no fat grub concealed in it, remove the soil to the depth of a foot, and add fresh before planting. Before doing so try what a strong watering of lime and soot would do. Birds are our best friends for thinning these marauders, and, as they remain in the larva state fully three years, the destruction they do to crops, to potatoes, and even to such ornamental plants as *Cerastium*, is very great indeed. The wireworm is even a worse larva if possible, as it exists in that state some five years, but a little for scattered on the ground and to the ground will generally send it off, and when present among crops, Potatoes and Carrots may be inserted in the soil as traps, and be examined every morning. The Musk plant will make a good bordering for bedding Pelargoniums and other things, but unless well watered it will die down early in the autumn. The herbaceous plant enclosed is *Arabis alba variegata*. The variegated *Vinca* makes a good edging plant.

WHITE BLOTCH ON PEACHES (*Idem*).—We think you must have had a little mildew on the Peaches last season, and that has increased this season. The blotches on the fruit are either the result of mildew, or of the sunstroke when the fruit was wet, and little or no air admitted to the house. We think it is mildew, and in that case would dust the parts with sulphur, dash sulphur paint on any open parts of the wall, give more air, and keep the atmosphere drier.

PRUNING LAURENTS (W. H. D.).—The Laurents may be pruned in winter, but better still in spring, before the buds break, but when they show signs of moving. If for timber and planted rather thickly they will need no pruning, and if for picturesque ornament they will merely need a little regulating, and that will often be as well let alone.

GOLDEN FEVERFEW (*Idem*).—The Golden Feverfew makes a good bedding plant, and will do best as an edging. It bears nipping or cutting to any height well.

ANTS (M. A. E.).—Ants do harm in greenhouses and beehouses, especially where fruit is grown. A little sugar and arsenic, either dry or in a liquid state, will tempt them. Cover it over to keep animals getting to it, leaving an opening, say of one-eighth of an inch for the ants to enter. We have also put honey and water in a pot, and then the honey stuck on their legs and trapped them by hundreds. Watering their haunts with guano or other ammoniacal water will expel them. A gentleman lately

told us that ants kept down the green fly in his houses, but we do not believe it. The artful busy ants treat a fat green fly much as we treat a milch cow, and in either case, fly or cow, are too valuable to be destroyed by those who are nourished by either.—R. F.

EUCODONOPSIS NAGELIODES (A. Y.).—The following description of this was given in "The Gardeners' Year-Book," for 1867:—"A beautiful dwarf stove perennial with the habit of a Gloxinia, the leaves cordate ovate, deep green, and the ventricose flowers rose colour, dotted in the manner of a Tydaea, and deflexed from the top of a stalk supporting them above the leaves. It is a hybrid between Eucodonia Ehrenbergii and Nagelia zebrina splendens."

ACTION OF NAPHTHALINE ON INSECTS.—The son of the late distinguished

Professor Pelouze, M. Eugène Pelouze, has found that naphthaline prevents plants from being attacked by insects. It neither kills the plants nor the insects, but scares the latter away. A very small quantity suffices. —(Scientific Review.) A correspondent (J. Tate), wishes to know how the naphthaline is applied.

AGRICUS FIMENTARIS (Mrs. C.).—It was a Coprinus, although called as above in the letter read at the meeting. A correct drawing of Scilla verna has been published, and a copy will be sent to you gratis if you send your address to our office.

NAMES OF PLANTS (F. C.).—*Crataegus crus-galli*. (H. N. L.).—The plant you enclosed is not *Viola cornuta*. Of *V. auricula* we never heard. We cannot determine the name of a plant from the leaves alone. (M. H. A.).—*Euonymus latifolius*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending May 26th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

CHICKENS DYING IN THE SHELLS.

In the early days of advertising, before small men and new establishments started by making their merits known in half-a-sheet, or, at least, a column of the *Times*, there was a pertinacious advertiser who addressed all England, of every sex and station, by giving them to understand that sooner or later they must do so, but in the meantime the advertiser asked of every Briton this question—"Do you bruise your oats yet?"

Everybody does not keep poultry, everybody will not, but many people do. We are beset with letters asking why chickens die in the shell instead of emerging from it; why hens do not bring their chickens off punctually. We answer all their questions with another: Do you moisten your eggs yet? If you do not, there is the cure for all your troubles, the solution of all your difficulties.

Partridges, Pheasants, and Grouse seem to be more successful at hatching than our domestic fowls that have all known "means and appliances" to boot. The truth is, their eggs are thoroughly wetted twice every day. At morning and evening the hens leave their eggs to feed: they go in among the damp grass covered with dew, and come back wetted through, especially on the breast that is immediately in contact with the eggs. The hen does not even shake herself before she sits on them. Every egg is well soaked, and the moisture penetrating to the membrane lining the inside of the shell keeps it soft; whereas, especially in this dry and hot weather, if the hen is merely taken off her eggs for half an hour, and they are not moistened, the membrane becomes as dark and tough as india-rubber. The chickens cannot get out. For a full week before hatching time when the hen leaves her eggs, dip your hand in water, withdraw it while streaming, and wring it over the eggs.

A popular writer says, "We are all more or less remiss in turning our respective mangles;" and this hatching season, as usual, many who have neglected a few simple rules are unsuccessful, make a trouble and disappointment of what is really very easy and amusing, and blame anything but their own mismanagement.

I always avoid heavy Dorkings and Cochins as sitters, so have no losses through their awkwardness, and make my hens as tame and manageable as possible.

This has been an excellent season, especially with eggs from a distance—as an instance, thirteen Golden-spangled Hamburgs from Mr. W. A. Hyde, Hurst, near Ashton-under-Lyne, distance two hundred miles, produced eleven uncommonly strong chickens. The hen sat on a turf, with very little straw, was attended to daily, and after the second week, the weather being very dry, had her breast wetted, and actually went on the eggs dripping. This facilitates the escape of the chickens from

the shell, and adds materially to their strength; so does a constant change of food. Spratt's Prairie beef meal is excellent in this way. Should any have indigestion and fever, a pill composed of camphor and aloes, from a quarter to half a grain of each ingredient, according to the size of the patient, is very effective, and may be repeated with safety night and morning until the excessive thirst is removed.—HENRICUS.

THIS SEASON'S HATCHING—TREATMENT OF HEN.

In reply to M. G. Hastilow and "VERITAS" I add a few notes on the above subjects, first giving my own hatching experience.

When hatched.	No. set.	No. hatched.	When hatched.	No. set.	No. hatched.
Feb.	7	0	April 16	19	9
Feb.	9	0	April 25*	12	6
Feb.	9	0	April 25+	12	2
March 1	10	7	May 2	10	8
March 21*	10	3	May 9*	10	6
March 26	10	4	May 11*	13	11
April 13	10	6			

All the eggs were Brahmas. Those marked (+) were sent me, and the nest marked (*) was bought, which may account for the unusually bad result! The first three sittings each contained from four to six birds dead at about a week old, proving that the eggs were chilled, the others being clear; and the subsequent hatches till the warm weather set in also contained several eggs added at different dates.

I can assure Mr. Hastilow that my friend who lost ten broods of Cochins is too veteran an exhibitor and old a hand to make the mistake he supposes, of setting too many eggs, of which he quite correctly states the inevitable result, unless we do as the "successful old dame" "Y. B. A. Z." alludes to, but whom I agree with him in not copying, who sets her eggs in hot weather, when they will almost hatch themselves, and, of course, need little care. At such seasons we poor amateurs ourselves have little to complain of, and often like her hatch every egg. And, by the way, my last brood of eleven would have been thirteen had I taken a little more care, for there were healthy live chicks in the other two eggs; but when half hatched they got tucked into empty shells and stifled—not uncommon in a large brood, and always fatal if not discovered and remedied in time.

With regard to failure in early hatches, I cannot do better than quote a paragraph from a Scotch friend and brother fancier, who every now and then writes me a long letter, which I never read without pleasure, and very seldom without profit. The other day, commenting on the success of a nest from me which hatched very well compared with two sittings of his own set the same day, which almost totally failed, though all the eggs were good, he said, "I am sure this was how it happened. The two hens did not dust themselves well, and when finally lifted off the nests were as full of vermin as they could possibly be. Now a hen in such a case keeps pecking at herself all day

and night at intervals, and some of the eggs get chilled. Again, I often go at night to see the sitting hens, and with a young hen it is quite common to find one or more eggs out from under her, even if she has only seven or eight eggs. As they all come outside in turn, this must do much to spoil the whole brood."

The last remark I can corroborate from my own experience. If the hen be not too heavy the fault can be guarded against by making rather a deep hollow in the nest, which keeps the eggs together; but a large hen often breaks eggs in a nest so made.

And now in reply to the kindly request of "VERITAS," that I would give my own views upon his courteous communication, I must frankly admit "that 'Nemo' does not attend to his sitting hens so well as he might." It is, alas, too true; but when I inform him that my hobby has to be ridden within the precincts of a small town garden, and that my business avocations require my presence every morning by 6 A.M., he will understand that this arises "from circumstances over which I have no control." That I am not ignorant of the plan he recommends may, perhaps, be proved by the fact that in a work on poultry, which most readers of "our Journal" know to be written by me, I have given, from "Poules et Oufs" (a sort of compendium of "Le Poultry"), not only a description of the process, but the very engravings (by permission) with which it is illustrated; still I do not think the French system adapted to this country for several reasons. In the first place, in our climate the hens would become infested with vermin if only allowed to dust themselves now and then, and the eggs get chilled, as my friend describes, unless, as the French do, an apartment is set apart for the process, and kept warm. Further, except in cold weather, I incline to the opinion that half an hour's absence is better for the eggs than a very short period. I may be singular in this notion; but when the weather gets warm I have never found that a very close sitter brought such good broods as one which remained off a fair time (possibly my Scotch friend again!) In the early days of incubators the eggs were kept heated without any intermission; but although this seems to answer perfectly in Egypt, I believe that here a periodic cooling is found important to success. But, lastly and chiefly, I altogether differ from "VERITAS" in his opinion, that chickens thus hatched are stronger than those produced on the ground. It is necessary, to have any success at all, that the eggs be damped, and by adopting this precaution chicks may be hatched on a shelf with no difficulty; but my experience is, that apart from all question of moisture, there is something in the ground itself (by ground I mean real earth), which gives a vigour to the broods nothing else can impart. "VERITAS" confesses to having lost many. It will be seen I have had a tolerable number, and scarcely any have died, whilst those few are nearly all accidents, or from one brood, whose mother from the first stood up all day instead of brooding them as she should do.

Another objection is, that very many hens are not quiet enough to be put back in their nests by hand. Cochins and some Dorkings will do so, but with many you would find your bird all "alive and kicking," to the damage of the egg shells. On the whole, therefore, while I believe that for very early broods, with quiet hens, some such plan as "VERITAS" describes may be adopted with advantage where possible, I far prefer the natural method of giving the hen a small run and leaving her to herself in ordinary seasons. The run should be small, and she should be alone in it; with these conditions and a proper nest I believe that the average result will surpass that of any other treatment, if the number of chicks actually reared to maturity are, as they should be, taken into the account.

With regard to packing, the last eggs I hatched and which, so far as they themselves were concerned, it will be seen were, without exception, fertile and vigorous, came to me from Lancashire and were thus packed. Each egg was wrapped in paper and then enveloped in a wisp of hay. Thus guarded they were bedded rather loosely but steadily in a small flat-topped hamper, a layer of hay about 2 inches deep being placed over and under them. Hay was also padded between the eggs and the sides of the basket. This is a first-rate method, if anything superior to bran, as described by me the other day, but I would use either according to the journey, weather, and other circumstances.—NEMO.

P.S.—I cannot exactly give reasons, but I have a very strong impression that, entirely apart from temperature, an east wind has a very prejudicial or at least retarding influence upon

hatching. Can any of your readers either confirm or contradict this from their own experience?

ON POULTRY SHOWS IN GENERAL AND ONE IN PARTICULAR.

ONE of the main objects in securing prosperity to poultry shows, is to inspire the exhibitors with confidence; but not often is that taken into consideration. The question naturally arises, How can it be effected? and my object is to answer that question.

I object to any of the members of the committee showing their own specimens for competition. As a general rule, and where practicable, the committeemen are chosen from those taking an interest in the breeding and rearing of fancy poultry, &c., which is not what I object to, only (except in rare cases) they generally study their own interests before that of the show, and in some cases even make their office a means of furthering the object they have in view. Now, I ask, would it not be wiser, if for that once, the committee, or rather intending exhibitors on the committee, would withhold their specimens from exhibition? Perhaps there may be some who think, that in excluding the committee I have taken too wide a range. Well, then, in illustrating my case, I will only object to secretaries showing for competition. They, at least, ought never to do so (and one having the interest of the show at heart would not), and for these reasons: They know every entry, and can either enter their own specimens or not, according to pleasure, or, what is more probable, their chance of obtaining a prize. In illustration I beg to submit the following:—Suppose a secretary is awarded a medal or other prize, with a pair of birds of far inferior merit to others exhibiting for that same prize, what is the inference many would draw? Again, suppose three prizes are advertised for award to a certain class, the first and second are given, but the third is withheld (not for want of merit, as the specimens are highly commended), and given to a single hen belonging to the secretary, what is the inference drawn? Another case, and I have done. Suppose the judge is a dealer, amongst the exhibitors there may be one or more of his customers—say, for instance, the secretary is. The judge recognises his birds, and awards them prizes. What, I ask, again, would be the inference many would draw?—CAROLINA DUCK.

BREEDING PILE GAME FOWLS.

I QUITE dissent from "NEWMARKET'S" views on the breeding of Piles, and other cross-breeds. He describes the old celebrated Cheshire Piles as white-legged, white skinned birds. I happened to have the acquaintance of the late Mr. Ashley, who was the originator of these birds, and, in fact, bred almost all the Cheshire Piles, and I am very intimately acquainted with his son, the present Mr. R. Ashley, who, I think, breeds as many and as good birds as any man in England, often supplying Mr. Fletcher, Mr. Brierley, and others, who are not, with the exception of Mr. Akroyd, breeders, but buy and show, and do not breed. Well, the late Mr. Ashley bred these Piles from white-legged Black Reds and White Game. They were but very few in number, and as they were not found so good as desired, although fair birds, they were crossed with willow-legged Black Reds, thereby giving the yellow leg and yellow skin. This breed is considered the original Cheshire Pile.

"NEWMARKET" says that the white-legged white-skinned birds are good, if well bred. This only puts them in the same position as any well-bred bird, and if not well bred it is not a good bird. I would ask, Where are now the Cheshire Pile, and the Lemon Pile of Lord Derby? neither, I believe, to be compared with the present Blood Piles for beauty or courage, for show or pit purposes. These remarks are gathered from upwards of fifty years' experience in breeding Piles.

I also take exception to "NEWMARKET'S" remarks on Greys being bred from Brown Reds. Greys bred from or crossed with Brown Reds have nothing to recommend them but their fighting qualities, being the ugliest Game birds I know. They are mottle-breasted, "toad-bellied," both defects entirely destroying their chance of prizes. But while entirely dissenting from "NEWMARKET" in the above particulars, I think his general description of Game fowls is correct, as, for instance, that Brown Reds should have the gipsy face, the hens having a brown-marbled, or laced body; but where are the judges that would give prizes to hens not having "rook bodies?"

Black Reds should have clean red faces, but if we are to "improve on Nature," and give our Brown Reds the clean red face, shall we not also give them the shape, and looseness and softness of feather of the Black Red, instead of the beautiful symmetry, closeness and hardness of feather, so essential to the Brown Red? If we cross breeds like Black Reds and Brown Reds, how are we to get one peculiarity without another?

I should have liked to have had my say on tails, but am afraid I am occupying too much space.—CHANTICLEER, *Nantwich*.

LIGHT VERSUS DARK BRAHMA POOTRAS.

IF any of our noted breeders of Dark Brahmas intend accepting my challenge they must do so before June be out, as I consider they have had quite time enough to think about it, if they intend to meet me. "Nemo" was quite right in questioning my additional conditions; and in reply, I beg to state I do not wish any concessions from the "Standard of Excellence," simply the additions thereto as mentioned in my challenge. My reasons for such shall be given at some future time.—F. CROOK, *Vine Cottage, Forest Hill*.

CANKER AND ROUP IN PIGEONS.

HAVING read the whole of the correspondence upon these subjects in your Journal, I felt inclined to send you a brief outline of my experience in the matter during the last two months, hoping that it may bring forward some one who can throw more light upon the matter, for we appear still to be in the dark both as to cause and remedy.

The roup first made its appearance in my loft in the beginning of March. It showed itself about the same time in two young Carriers and one young Dragon, all in separate nests. The old birds at that time were healthy; the young birds died, but not before two of the old ones had taken it. From that time to the present it has continued spreading. I have tried Mr. Heath's and Mr. Rose's remedies; the effect was beneficial in some cases, in others the birds died under the treatment. After losing several of my best birds I tried Baily's roup pills; the effect so far has been good, but as the time is short I cannot speak positively upon it. Certainly I have not lost one bird since, although I had some bad cases that I tried them upon.

After carefully watching the effect of the disease for several weeks I am surprised that any experienced fancier should say roup is not contagious. The cases brought forward do not prove it to my satisfaction. I have several cases in which one bird is very much affected with the disease, but the mate is in perfect health; but I have more cases the reverse of that. I will give you one instance. I have a Short-faced Kite hen that took the roup in March. She was mated to an Almond cock; he caught it of the hen and died. I then put to her another cock bird that was in perfect health, and he caught the disease and died. She has partially recovered. I could state several other cases which to me demonstrate that roup is highly contagious. Who would say that the small pox is not contagious? and yet how frequently it attacks only one individual in a large family!

The canker I care but little about; if taken in time I find it easily cured, although I have generally found that when one young one in the nest is attacked, the other takes it unless the remedy is applied promptly.

Being an amateur I read with interest the articles on matching for colour, &c., and have been waiting to see some of the promises fulfilled in the shape of other letters upon similar points. There is a great want felt by amateurs which I am sure could be well supplied by your able correspondents. We read often enough what we should not do, but we want to know what we should do. We have heard what is a bad match for Black Pouters, but no one has said what is the best. A few practical letters like Mr. Simpson's would do much to improve the various strains of birds. I hope we shall see them, but above all I would like to see every letter written in a good spirit. I think if we differ in opinion we should still display the spirit of friendship.—J. WREN, *Lowestoft*.

P.S.—I have found that all the young ones died that were affected by the roup. No remedy that I could try would save them, and the disease generally assumed a different form in the old birds which died from what it did in those which recovered.

STAVELEY POULTRY SHOW.—The Committee of the Staveley Poultry Show have just issued the prize schedule of their first

Exhibition. We hope it will prove a success. Six silver cups are comprised in the schedule, besides a considerable amount of money prizes. The Committee on their prize sheets state the names of the two gentlemen engaged as Judges.

A GUIDE TO CANARY-BREEDING.—No. 6.

AS I stated at the commencement of these brief articles, I have not attempted a learned disquisition on Canaries. I have tried to make them what they profess to be, and what I wish the Editors of the Journal had entitled them, "Au A B C Guide," with due emphasis on the A B C. I am somewhat sorry that I have provoked no discussion, but I infer from this that the matter I have adduced has been so very elementary as, perhaps, to leave but little room for any. When I have inserted my paper-knife week after week into the uncut folios of the Journal, always commencing at the "Poultry, Bee, and Household Chronicle," as I have no doubt those genial souls the "WILTSHIRE RECTOR" and "D., *Deal*," do at the other end, I have often admired the plucky manner in which "NEW-MARKET" and his opponents buckle on their spurs and fight on behalf of their combative *protégés*. Pigeons, too, can evoke columns of spirited discussion; while the "DEVONSHIRE BEE-KEEPER" and other apirians have a friendly bout now and then, enriching our stock of knowledge from their own well-stored hives. "D., *Deal*," who is equally at home among roses, camellias, and potatoes, will relate his experience, and tell us the names of a score of approved sorts of either, with a detailed statistical account of their merits or faults. Each and every pursuit which may be supposed to find a home in the country gentleman's house has its niche in your Journal, and friends who maintain all shades of opinion. But excepting a solitary query now and then, one hears but little *pro* or *con*. respecting a fancy which numbers its supporters by the thousand. I thought that the proposition which emanated from Polefield Hall, and which was supported by Mr. Warren, of Southampton, and myself, would have met with a ready response; and that your columns would, week after week, have teemed with articles from enthusiastic correspondents, till the subject was thoroughly ventilated, and something like an all-England association formed, with its complete schedule and standard of excellence. Granted that breeders are too fully occupied with their birds just now to pay much attention to these matters, but I hope that before the autumn shows commence some definite conclusion will be arrived at touching certain points which the liberal extension of prize schedules is beginning to develope. The value of a perfect cap in a Lizard; what constitutes the difference between marking and variegation in Norwich and other classes; whether Ticked and Variegated Belgians should be shown in the same class; the proper classification of Crested Norwich, &c., are questions of interest which I should like to see discussed.

In drawing these articles to a close, I will just add a word or two on running one cock with two or more hens, which it is sometimes advisable to do. The *modus operandi* is either to keep him in a separate cage, and introduce him to the hens when they evince a disposition to nest, and then leave the rest to the good breeding and feeding qualities of the hens, or to single out one, the best, as his mate, and confine him with her till she lays her first egg, when he can be introduced to a second. By the time she has built and laid, the first will have chipped, when he can be returned to his first love to assist in family duties. I have seen two hens in one cage each attending to her own nest, and each receiving attentions from the cock without showing any symptoms of jealousy, and it is not uncommon in such a case to find either hen assisting the other in feeding. Polygamy is tolerated among Canaries as among other domesticated feathered tribes, and the cock will be found faithful to all his loves, even after a very prolonged absence.

I may at a future date, as occasion may suggest, request the favour of a corner in these columns in advocating the claims of the Canary. Few hobbies pay their working expenses better, and Mr. Bedwell's observation, which I quoted some time ago, showing that the sale lists of our exhibitions prove it to be as remunerative as "breeding pelargoniums or bees" is very true. No one can spend an hour in a breeding-room without learning lessons of kindness, gentleness, and affection. I spend many an hour there with my children—no greater treat to one than to dispatch him with my basket to the fields for the daily supply of green food, and no greater pleasure to

another than to allow her to tidy the room, while a third is too young to do much else than purloin my egg, build houses with the sand, upset the water, and other amusements. Still, who can resist the gentle tap at the door, and "Papa, may Jacky come in and help?"—W. A. BLAKSTON, *Secretary, North of England Ornithological Association.*

HINTS ON CANARY-BREEDING.

I AM very successful in breeding Canaries, but I like them to look pretty as well as comfortable. I take away the two ugly boxes meant for nests, and also the wires, as I like only a pair of birds in each cage. I next arrange little branches of pretty evergreens in the place of the boxes (avoiding Box, for its smell is very unpleasant), and then a handful of hay. Afterwards I hang up the nest bags sold for birds, and add fresh moss and white feathers. I like to see the birds building.

I always open the cage door, and give the hen the option of bathing whilst she is sitting by placing a glass dish on the top of the cage. I take the opportunity of cleaning the cage whilst she is out. They always are ready to go in again when everything is ready for them; and if the plan of the evergreens is once tried I am sure the two square boxes would never be used again.—AN OLD HEN.

FECUNDITY OF THE QUEEN BEE.

I SEE in the report of the May meeting of the Entomological Society, which appeared in page 361 of "our Journal," that Mr. Desborough stated that "a single queen had produced at many as 108,000 eggs, which would be about 20,000 a-year." There can be little doubt that Mr. Desborough has arrived at this ridiculously low estimate of the breeding powers of the queen bee by observing one in a unicomb hive, where her fecundity has been thwarted and rendered of no avail by the very limited number of breeding cells which she has had at her disposal. Dzierzon gives four years as the average duration of life in the queen bee, and considers that during that period an especially prolific queen may lay more than 1,000,000 eggs. No one who is acquainted with the internal economy of a strongstock will consider this an over-estimate. It is nothing unusual to see from 15,000 to 20,000 cells occupied by brood during certainly three months of the year, and when we add to this period the spring and autumn months, during which breeding takes place, first in an increasing ratio until it reaches the culminating point which I have indicated above, and afterwards decreasing, until in October or November it entirely ceases, and consider that during this protracted period the tenants of the brood cells are renewed every three weeks, we may form some idea of the enormous fecundity of the queen bee.—A DEVONSHIRE BEE-KEEPER.

NEW BOOK.

Profitable Bee-keeping on Improved Principles, Chiefly Designed for the Use of Cottagers. By the Rev. P. V. M. FILLEUL, M.A. London: Christian Knowledge Society.

This is a reprint of a series of papers on profitable bee-keeping from the pen of the Rev. P. V. M. Filleul, better known to the readers of this Journal first as the "COUNTRY CURATE," and more recently as "B. & W.," which appeared last year in the "People's Magazine."

The highest praise which we can award to this little brochure is to say that it is eminently practical and worthy of its accomplished author, in whose words we may state that "if the reader will only be careful to follow its instructions, he will find bee-keeping far more sure, not more troublesome, and much more profitable than he has yet found it." We extract the following description of the wooden hive recommended by Mr. Filleul:—"One of the best hives that can be made is a common good-sized bucket without a handle, and with the bottom knocked out. It will last almost for ever, which cannot be said of any sort of straw hive. In this respect it will be found much cheaper in the end. Turn it up on a bench or stool with its broadest end uppermost, and cover it with a flat round board, and you have a most excellent bee hive. Any cooper would make these without a bottom cheaper than a bucket. The board at the top must have a 2-inch hole in the middle of it, and must lie so close upon the hive that the bees

shall find no crack or crevice by which to creep in or out. At the same time it is better not to fasten this top to the hive, as the bees very soon fasten it down for themselves. It is well, however, to place a flat stone or thick slate upon it, with a brick or two to prevent it from curling or warping, and the whole should be covered over with an earthenware pan to shoot off the rain. The hole in the top board can be stopped up with a bung, or covered over with a piece of slate. A hive of this shape can easily be made of straw, but in this case it is better to work the round of straw both at top and bottom on a hoop of stout wood, such as coopers use. These hoops will preserve the straw much longer, and make the hive sit well on its stand, and the wooden board on its top.

"The use of this hive is great, for, in the first place, it is very convenient for putting a cap on in the honey season; but its advantage will chiefly appear in the end of summer at the time of the honey harvest. One of the greatest objections to the common hive is the impossibility of taking away the honey without destroying a quantity of comb, which would be of value to the bees another year—much more valuable than the wax to be got from them would be to the bee-master. Not only so; there is often an immense quantity of brood (or young unhatched bees), destroyed, which if preserved would add greatly to the prosperity of the hive another year, as these young bees will live till spring. Now, this hive with a flat and moveable top will remedy both these evils; for, after getting rid of the old bees, you may remove the top board by passing a knife with a thin blade completely under it all round, so as to separate the combs from it. Then the comb which contains the honey can be easily cut out without injuring the lower part of the combs at all, especially if there are sticks in the middle of the hive to support them."

WIDTH OF ENTRANCE TO SUPERS.

I AM putting supers on my Woodbury hives. Can you inform me the best way to prevent the queen entering? I had a large quantity of honey spoiled last year from this cause. I have this year tried wires three-sixteenths of an inch apart, which appear to answer very well, with the exception of one, in which I used brass wires, I think a little closer. The bees entered the super, but in the course of two days I found about two thousand dead, apparently all young bees. Should you think the entrance too narrow for them to return, or were they poisoned by the brass?—S. THORNE.

[We think the brass wires must have been rather too close together, as we do not believe the bees to have been poisoned by them. We should be glad if others would afford us the benefit of their experience upon the point with regard to which information is sought by our correspondent, as we are not ourselves qualified by experience to offer an opinion upon it.]

SILKWORMS.—We are informed by Mr. L. Harman, of Catton, near Norwich, that he has 200,000 silkworms, consisting of mulberry breeds, producing yellow, white, and green silk, and our readers may embrace the opportunity of making experiments in silkworm-rearing if they apply to him during the next fortnight.

SILKWORM-REARING IN ENGLAND.—No. 10.

AN ounce of silkworms' eggs, numbering between forty and fifty thousand, having been hatched, it is necessary to follow a good system of management in order to rear the worms. I shall premise all the worms to have come forth from the eggs on the same day, although in reality they may have done so on four consecutive days, and that they occupy four sheets of paper or calico, if the latter be used, of the dimensions already named. By judicious management the majority of the worms may be brought to spin together, or within a couple of days of each other—viz., by placing the first hatched on the lower stages, and the last on the higher ones. The higher the position the warmer, and the worms so placed will eat more voraciously than those lower down, and, consequently, will grow faster. However, their arriving at maturity on three or four consecutive days is of no particular consequence, but where many are kept it is advantageous, for the work of attending to them is better divided.

To rear the worms, from 1500 to 2000 lbs. weight of mulberry

leaves are required. The precise quantity it is impossible to fix, as it varies much according to quality and other circumstances. I will not say it is always necessary to weigh the leaves, for any person will soon understand by the consumption what quantity to supply. With regard to the surface the worms should occupy, between every two there should always be at least the space of a third. The more they are at liberty to crawl about, the purer is the air around them, and, consequently, the greater is the chance of their growing strong and healthy. This is one of the important points in silkworm-rearing. When worms are placed on a sheet of paper, its surface should never be even half filled with them, so that plenty of room may be allowed for their growth.

The First Period and Sleep.—The first period, up to the first sleep, lasts about six days, during which time the worms are to be fed every five hours. They will consume from 12 to 15 lbs. of clean, fresh, finely-cut leaves, which are to be lightly dropped over them. On the first day a few ounces will be enough, on the second 2 or 3 lbs. will be required, and the quantity must be gradually increased on the third and fourth days, the worms requiring more food, but their demands diminish sensibly on the fifth and sixth days, because their dormant state is at hand.

On the morning of the fifth day it is desirable to shift the young worms to clean sheets of paper, forming two parts of one, by dividing the insects. Many persons leave this operation until after the sleep, but I consider this early cleanliness goes far in establishing the future health of the silkworms. They will occupy, by the time the first sleep comes on, about 20 feet of space.

The operation of removing them to the fresh sheets of paper is executed by giving the worms their first meal of whole leaves, or leaves merely torn up the middle. The leaves are to be laid over them, stalk upwards, and by these they are lifted away as soon as filled by the worms, and put where required. The worms remaining, because they did not go on the leaves, must be again covered with leaves, and afterwards any left can be lifted away by some portion of the old leaves.

This first sleep lasts about two days, after which the worms cast their skins, and are soon again in want of food. During the sleep keep the temperature at 70°, whatever slight fall may at other times have occurred. Do not, now the worms are small, attempt to touch them, for they are easily crushed; indeed, great care is requisite even when large, otherwise they seem to suffer. In feeding, distribute the cut leaves equally to the worms, so that all may have the chance of eating without loss of time, otherwise their sleeps cannot come on together, which will make it necessary to continue feeding those which are later.

The Second Period and Sleep.—The second period like the first lasts about six days, during which time the worms will eat about 40 lbs. of cut leaves. On the first and second days they will require 10 lbs. or 12 lbs.; on the third and fourth, about 20 lbs.; on the fourth and fifth, 10 lbs. By the time this sleep comes on they will occupy 35 or 40 feet of space, or nearly one entire stage, if allowed plenty of room. No papers should be allowed to become too full of worms without dividing these, which operation will generally be found necessary the day after the first sleep, and again on the fifth day before the second sleep. On each of such divisions the insects are transferred to fresh papers as before described, and the refuse, dirt, &c., removed.

The meals should be repeated every five hours. It is customary on the Continent to give the last meal plentifully at 11 p.m., and the first in the morning as soon as sufficiently light for one to see, which would be about 4 or half-past 4 a.m. As the worms go into their sleep give frequent light meals to those which are backward, to push them along. Inequality among them arises from neglecting this, and not keeping them in a space proportioned to their growth. It often happens, even with every care, that some of the first to sleep, awake and shoot their skins before others on the same paper begin to sleep. In this case light meals must be continued frequently until all take their sleep. Then immediately remove the forward worms upon whole leaves, or leaves attached to the young shoots, to other papers, leaving the sleeping ones until they again become active, and can be transferred to another paper by themselves. There is a method much adopted to maintain equality, by observing when all are asleep, and then starving the most forward on waking, even for twenty hours, to await the later ones. I condemn this as unnatural, for al-

though they do not die in consequence of going without food even for several days, they must suffer. I do not, however, think any ill effect follows confining this starving to intervals of eight hours from meal to meal.—L. HARMAN, JUN.

OUR LETTER BOX.

WHITE DORKINGS (White Dorking).—It is said that the original Dorking was a white fowl. There is no proof of it. A Mr. Evelyn is said to have introduced them into Surrey. They are excellent birds, second only to the Grey of the same breed. Their colour has hindered their being more numerous kept. They are beautiful in a clean atmosphere, but they show smoke; they will not do in towns. An average bird of the breed will cost 25s. They may have double or single combs, but a pen must not be composed of both, and it is advisable to have all the birds in a yard either with double or single combs. The rules for them are the same as for the Grey. They must be well made, have five claws, white legs, and square bodies, and be of large size. We have seen them almost as large as the Grey. Combs are no test of purity.

DEATH AMONG GREY DORKINGS (F. S.).—We are at a loss even to guess the cause of the death of your Dorkings. They have all the advantages of locality, and your feeding seems judicious. Give them camphor and wormwood in their water. If they have it not, provide them and the hen with plenty of dust for the necessary dust bath. If the hen is not confined, confine her; do not let her drag the chickens about, as hens often do in rain and dew till they perish. Are they fed at daybreak? If not that will account for the death of some of them. They must have food as soon as they are able to see it. Failing that they perish.

WEAK FEET IN CHICKENS (A Constant Reader).—What do you call the stump of the leg? Do they walk or rest on their knees? If they do, they are suffering from general debility, and can only be restored by generous diet, such as chopped cooked meat, boiled egg, ground oats, wormwood, and bread and ale. If they walk on the ball of the foot that may generally be traced to bad flooring of the poultry house, such as stone, wood, or brick. If you have such remove it.

FEEDING RABBITS (A. T.).—Tame Rabbits require a few oats, plenty of bran, green food, and water. They also require to be kept clean. You must judge the quantity necessary by watching what they eat, not what they waste.

CAPONISING (Idem).—Making capons is not anywhere considered a simple operation. We hold it to be wanton and useless cruelty. The young fowls in this country that are only just arrived at the age when the operation becomes possible, are larger and better than the French capon that is ten months old. Instead of resorting to cruelty to enable you to eat poultry all the year, you will find it a great economy of food and saving of trouble if you will arrange your hatching so that you will have tender birds of proper age for table every month. The London poulterers are without rivals in Europe for the quality of their poultry; and while "the consumptive capon on the table" is still found on the continent, we in England have fowls larger and heavier, much younger, and more tender, that have consumed only half the food, and that are not the survivors of scores.

GAPES (C. X. H.).—If you make the bird inhale the vapour of spirits of turpentine, let the bird remain in the box five minutes each time. Give it also a pill of camphor the size of a pea daily.

BOILED EGGS FOR SITTING (J. L. L.).—We said from "the neighbourhood of Halifax," not, as you say, "at Halifax." We cannot refer to the subject further. You can have a stamped copy of our Journal if you order it.

SUBTERRANEOUS POULTRY SHOWS (C. A. J.).—We know of no better guide to them than our weekly-published list. Sea Anemones will not permanently thrive in a marine aquarium, and least of all in one which never has the water changed.

TEN CANARIES EATING THEIR EGGS (R. N. A.).—"I have never had a hen which persistently followed this bad habit. If it be done before she has laid her full complement, furnish her with a drop-nest, which is simply an ordinary nest with a hole in the bottom through which the egg falls into a chamber below, taking care, of course, that a suitable bed of cotton, wool, or other soft material be ready to receive it. If it be a confirmed habit, indulged in at any time during incubation, blow an egg and fill it with Cayenne pepper. This not being so palatable will, except with very depraved appetites, effect a cure. I know a hen, however, which, after having been cured last season by this treatment, has returned to her former propensity, and two eggs duly prepared have disappeared without any good results in the desired direction. I think I would try a rotten egg, as savoury as possible. Failing cure, give her eggs to a nurse; if she is not valuable, twist her neck."—W. A. BLAKSTON."

POISONING BLACK BEETLES (An Old Subscriber).—The article you referred to appeared in No. 353. The address is—Mr. Chase, chemist, 14, Holborn Bars, London.

LIMES AND ORANGE PEEL (Nullus).—We have no information relative to the subjects you name.

POULTRY MARKET.—MAY 27.

There is a slight improvement in trade, and the supply of goslings, ducklings, and chickens has somewhat increased. We hope there will soon be a steady demand at moderate but remunerative prices.

From observations taken near London during the last forty-one years, the average day temperature of the week is 70.3°; and its night temperature 46.8°. The greatest heat was 90°, on the 6th and 7th, 1846; and the lowest cold 33°, on the 5th, 1856. The greatest fall of rain was 1.48 inch.

THE CLOUDBERRY.

AMONG those of our native fruits which have not yet been brought under and improved by cultivation, this is undoubtedly one of the most interesting. Its popular name of Cloudberry, suggestive as it is of mist-enveloped mountain tops, is yet hardly descriptive of the situations in which it is most usually to be found, as these are generally at altitudes considerably lower than cloudland, on upland moors, or round the bases of our

Highland bens. Sometimes it occurs in scattered plants nestling here and there among the Heather, but more frequently in patches of from a few square yards to an acre in extent. It is, however, far from being a common plant in this country, to which circumstance may, perhaps, be attributed much of the interest it excites, as, throughout the Highlands, it is very unequally distributed, while in the southern counties I am not aware that it is to be found at all.

My first acquaintance with it, otherwise than from dried specimens, and equally dry descriptions in botanical works, took place in Banffshire some years ago. It was during one of those rare intervals when with some misgivings we busy plodders tear ourselves away from, and try to forget for the time being, all those thousand-and-one little cares and schemes, which, were they not more than counter-balanced by the love of gardening for its own sake, would soon make our path through life a worse than Abyssinian highway, to enjoy for once a holiday, if a week of unlimited rambling through out-of-the-way places may be so called. Overlooking the extensive grounds and gardens of Cullen House, one of the seats of the Earl of Seafield, stands the Bin of Cullen, a high conical hill, from the top of which a splendid view can be had of the Moray Firth and the north-eastern seaboard, as far north as the Ness of Wick, and the jagged peaks of Caithness. Having been informed that round the sides of this hill the Cloudberry was to be found in great abundance, we set out from the gardens, and after traversing a mile of deer forest, began the ascent. It is no Mont Blanc, certainly, being only 1000 feet or so in height, yet, to some of us at least, there was as much freshness and novelty in the feat as though we had all been members of the Alpine Club, and were just about "to do" that great Swiss celebrity in the most approved style. As we ascended, the Scotch Pines became mere pigmies, and at last assumed an almost prostrate form, cowering down and leaning over to the inland side from the effects of the sea blasts. Failing to find the object of our search we made for the summit, where we spent an hour of uninterrupted pleasure in surveying the wondrously wild yet beautiful scenery which lay around and below us. Here we were almost within sight of the "ultima Thule" of the British Islands. Away to the south some two hundred miles lay a spot of ground crammed as full with objects demanding attention as Pandora's box was with ills to mankind, yet thoughts of these had no power to reach us here, but in their place

was time to gaze our fill at an expanse of land and sea which made one feel little to look at.

Descending by the opposite side, and picking up by the way some specimens of alpine plants strange to us, we at last came upon the little Rubus—no solitary patch of it, but a track covering one side of a slight ravine for 50 or 60 yards. This was towards the end of August, and the fruit was mostly gone, evidently eaten by grouse or other moor fowls; but it was apparent that the crop had been most plentiful, and sufficient was left for us to find that the berries have a peculiarly rich, vinous, and slightly acidulous taste. The plant itself is herbaceous, and seldom attains a height of more than 9 or 10 inches. The leaves, large in proportion, are simple, lobed, and serrated round the edges. The flower is whitish, and the fruit of a rich orange red and composed of a variable number of drupes, fewer and more irregularly clustered together than in the Raspberry or Bramble. In the Gaelic language it is called *Cori-bata-moon*, the signification of which I am unable to give. It is highly prized by the Highlanders, and large quantities are gathered during the season both for home use, being made into preserves, and for sending south. To the sportsman and his gillies, when enjoying their toilsome pastime under a broiling sun, it is also a welcome sight, and I have more than once been questioned by gentlemen, who were first made aware of its unique flavour during the shooting season, as to the possibility of bringing it under cultivation. So far as I am aware, however, no attempt has ever been made to do so, at least, none on a scale and with that degree of systematic persistency necessary to secure success; yet it seems highly probable that if it were crossed with some other herbaceous species of grosser habit (and there are several such), a variety more easily cultivated might be obtained. As it is, when transported from its native soil and air, it only lives; it will not grow, unless it be to grow "small by degrees and beautifully less;" for within the last few years I have several times met with it in gardens, but was always told it would not fruit.

The Cloudberry is said to attain a much larger size and finer flavour in Lapland and the northern parts of Norway and Sweden, but in notices of it given by travellers in these regions it seems to be not infrequently confounded with *Rubus arcticus*, which is a species of nearly similar habit, but with purplish fruit, and of even more agreeable taste. This again is given in most works on botany as a native of Scotland, and the Island of Mull is invariably quoted as one of its stations. There it is no longer to be found, nor is it, according to some of our best botanists, to be met with anywhere else in Scotland; so that either some abnormal form of *R. chama-morus* must have been mistaken for it, or it must have become extinct.—*ANGLICAN GARDENER.*

THE CULTURE AND PROPAGATION OF THE PELARGONIUM.

A few remarks on this subject founded upon experience may be useful to a numerous class of our readers; for

who amongst them does not grow Pelargoniums, which are to be found in the cottages of the most humble and in the gardens of the most wealthy? Those who are fond of plants possessing finely-marked foliage can have ample choice in the Golden Zonal and Tricolor-leaved sections; and then for beauty of foliage and richness of colouring in the flower, the stage Pelargonium is not easily surpassed; to this must be added easy cultivation. I do not wish to occupy space with any lengthened details, but only to offer a few hints on the propagation and after-management.

When I resided in Scotland I always preferred to propagate Pelargoniums in May, as they made much finer plants before winter; in the neighbourhood of London July and August are as suitable, but any time between the first and the last-named months will do. I am well aware at the same time that they may be propagated in any month in the year. For this purpose I prepare a number of clean 60-sized pots, by carefully crocking them, and placing a little moss over the crocks. I then fill them with a compost of fine loam and leaf mould, with the addition of a little silver sand, pressing it in so as to be moderately firm, place a thin layer of silver sand over the surface, and with a small dibber insert one cutting in the centre of each pot. In pressing the soil round the cutting care must be taken not to injure the part which is under ground. The best position for the cuttings is a shelf near the glass, and they ought to be placed there at once, and receive a good watering through a fine rose. They require no shading, except it be for a day or two if the sun's rays are particularly scorching. I propagate all the finer Zonal and Tricolor-leaved varieties in this way, as they have then a great advantage over plants rooted in boxes, or a number of cuttings placed together in larger pots; for separating the plants afterwards always gives them a serious check.

As soon as the small pots are full of roots the plants ought to be shifted into pots one size larger, and in growing Pelargoniums of whatever variety care must be taken not to overpot. Under proper management the plants will be as fine, and the flowers will be more perfect in small pots than they will be in larger ones. I continue to shift the plants as they require it until they receive their last shift, and I rarely plant a Pelargonium of any variety in a pot of a greater inside diameter than 8 inches.

The compost I use when I plant them in the pots in which they are intended to flower consists of pure turfy loam and one-eighth part of manure, composed of equal parts of cow dung and horse droppings, with enough silver sand to keep it open, and I add a little leaf mould when I can obtain it, but this last, I think, is immaterial.

The plants in every stage of their growth ought to be kept near the glass, and should on no account be crowded together; it is better in every way to have three good plants than six in the same space, if they have not enough of room to allow the foliage to expand properly.

Watering is most important, and especially so in the winter; at that time they require looking over about once a-week, and those that are quite dry may be watered. Of course, as the season advances, and the pots become full of roots, more water will be required. As soon as the trusses of flowers begin to appear, give liquid manure twice a-week, and the quantity used may be increased or the application withheld according to the strength of the plants. Too much manure water is a fertile cause of spot, as it affects the young and tender tips of the roots so that they cannot perform their functions. At this stage of growth none of the plants must be allowed to become very dry. When in flower they ought to be looked over twice a-day. There is one thing I ought not to omit to state, and that is to have the plants thoroughly cleansed from green fly before the blooms expand, as the tobacco smoke causes all the expanded flowers to drop off.

The best form of glass structure for growing Pelargoniums is a subject on which I would like to see some discussion in your columns, as well as which is the best form of glass structure for growing other sorts of plants. I believe that a half-span roof facing the south is the best for growing the stage Pelargoniums, and a span-roofed house with its end to the south the best for all the Zonal and variegated-leaved varieties. Of course they can be moved to any position in the greenhouse or conservatory when they are intended to keep that way.

I offer these few remarks at the present time, as I know they will be useful to numerous growers of this class of plants

who are also readers of your Journal, and to whom a few plain hints are valuable.—J. DOUGLAS.

STONES AND THEIR UTILITY IN A SOIL.

ABERCROMBIE and other old garden writers gave directions for the various soils used in potting to be very carefully sifted through a fine sieve, removing everything that was lumpy, whether of stone or earthy matter. This doctrine held good in many instances up to the period when gardening periodical publications made their appearance; but at last some innovator boldly attacked the practice, and a less finely-sifted potting material became the order of the day; even turfy bits of half-decomposed vegetable matter were allowed to take their place in the mixture, and soon, as if innovation could not be carried too far, these turfy pieces of material were thought to be better if taken direct from the place where grown and used the same day. This extreme, however, is but seldom adopted; nevertheless, fresh turfy soil, of which the grass may have been in a growing state from three to six months before, is thought to be the nearest approach to perfection that can be made in a potting soil, or one adapted for a fruit or conservatory border, assuming it not to be too stiff, and its qualities for a good pasture to have been established before. Now, I am not sure but we have often run into error on this score, and it is an attack on this practice in certain cases that the present article is intended to make, for there are often instances in which the carrying-out of the recommendation to use only decayed turf has not been satisfactory.

If we take a survey of the natural products of the earth in the shape of fine specimen trees, good agricultural crops, or other things on a large scale, we shall see that in very many cases one of the ingredients of the soil in which they are growing is very often left out in our composts—I mean stones. Perhaps the reader will be inclined to say, "And very properly left out, too," but I am not sure of that; on the contrary, the reverse of successful cultivation is the case when they are too extensively removed from some places, and this has been proved in many cases in the time of our grandfathers, or perhaps before, and they gained their experience no doubt in the first instance in that way which imparts conviction most truly—namely, by paying for it; bad crops following the gathering of stones from their land, and succeeding generations have found this practice wrong, as it is prohibited to some extent in many places. Now, if stones form such a necessary ingredient in the composition of a soil required to grow a crop of corn, a hedge, or a tree, why are they not equally so in the growth of plants of other kinds? We cannot say that stones are unnecessary, and that the soil is as well without them, for the fact of farming crops being diminished by the too-extensive gathering of the stones proves their presence in the soil to be necessary. This being admitted, why do we deny them a place in our potting-bench mixtures? Of late years it is true they have been admitted, and extensively, too, into our Vine borders, but cannot they be allowed for plants in pots that are large enough? It may, perhaps, be urged that the limited quantity of soil enclosed in a pot will not afford room for stones; but when we see the manner in which most of the plants grown in pots cling to the drainage, we are led to inquire why they would not relish more or less of stones as well as the broken pots. The latter is a less-natural product, and it is questionable whether it is better than stones or not. I imagine the utility of both consists in their retaining a certain quantity of moisture, which they part with when it is wanted to the roots that embrace them, and in this respect stone would seem as suitable a substance as the crocks, or perhaps more so, provided the stone used is in accordance with the soil it is mixed with, which is not always the case when artificial soils are formed, as will be shown hereafter.

I have been led into the foregoing notice of the utility of stones in the soil from the occurrence of a case in which they were wanting. Some alterations were being carried out on an elevated tract of thin stony land that was in pasture; a large quantity of turf was taken off to the usual thickness; it was cut to lay down again, and most people envied the gardener who had the good fortune to obtain so valuable an addition to his compost yard. The ground was very stony, but it would appear that the stones had been carefully picked off the top when it was laid down in grass, so that the sward could be pared off without many stones being in it, while below that the stones could not form less than three-fourths of the whole.

This turf was carted home and used as wanted; but, strange to say, it exhibited a tendency to run together into a more compact body than other turfy soil from ground of quite a stiff character, so that a much greater proportion of sand was necessary to keep it open, and the kind of sand to be had not being suitable to the composition of the soil, the result was not so satisfactory as was expected. Perhaps it may be asked, How did the grass grow on it? This is easily answered: the roots of the grass had access to the stony medium below, and the issue led me to infer that turf obtained from such a source was not a fair sample of the soil, and used alone its deficiency became apparent.

In confirmation of the opinion given above, I may mention a case which occurred here some years ago. Some beds of Rhododendrons were made on a soil apparently the very reverse of that in which the plant flourishes, it being a pale yellow-coloured soil mixed with three-fourths of its bulk of stones, varying in size from 3 lbs. or 4 lbs. weight to small ones, but not what are either called gravel or sand, as the stones were mostly angular. The ground being broken up some plants were put in without any additional material, and some had a portion of the turf taken off the same ground chopped up and put around their roots, and the plants planted in the latter manner did not do so well as those which had less attention paid them. The ground, I may remark, was so thickly covered with stones after the work was completed, that scarcely an inch of it was visible. Here was an instance in which stones were evidently of service in the case of one of our most fibrous-rooted plants, so densely fibrous, indeed, that it is not an easy matter to free the roots of the earthy material they are growing in; and yet these roots seemed to find their way around and between the stones that formed so important a proportion of the soil, and I was led to the belief that the very stone itself furnished its due share of the food the plants thrive upon; for although the latter did not succeed so well as they might have done in a proper peaty soil, they did much better than others in a good rich garden soil and in a situation apparently much more in accordance with their habits.—J. ROBSON.

IN-DOOR CLIMBERS.

PERGULARIA ODORATISSIMA.

PERGULARIA ODORATISSIMA was first introduced into this country as long since as the year 1784; but it is so seldom met with, that I hope the following account of its merits may be the means of placing it in a more favourable position than it now occupies.

Many beautiful old-fashioned stove climbers have doubtless been thrown out of cultivation from the change that has latterly taken place in the heating of garden structures. A few years ago tan was the material in general use for supplying bottom heat to Pine Apples, and large pots plunged in the corners of pineries for the most part contained such plants as that under notice. In such a position the roots had the chance of passing through the bottom of the pot and running amongst the tan, while the pot was a sufficient check to induce the plant to produce a greater profusion of bloom than it otherwise might have done. I do not know that we have gained much by our change in heating such places, except, perhaps, a little saving of labour and increased neatness. In most Pine stoves bottom heat is now supplied by hot water; and where that mode of heating is adopted there is hardly plunging material sufficient to cover the pots, and the dry heat underneath prevents the roots from spreading in that direction.

In the Pine stove here nothing but tan is employed for bottom heat, and a plant of the Pergularia is plunged in one corner. On renewing the tan a few weeks ago I found the roots running amongst the tan at 5 feet from the surface, as if they fully enjoyed their situation; and I maintain that climbers add great interest to such places, particularly as many of them will not grow in cooler houses.

Pergularia odoratissima is an evergreen twiner which grows freely when in good health, but, like some others, it requires time to make a good stem before it commences to flower well. As regards special treatment, when once the plant has covered the space intended for it all the shoots should be cut closely in, similar to the short pruning of Vines. The flower trusses issue from the axils of the leafstalks, and each shoot produces, according to the vigour of the plant, from three to six trusses, each composed of from thirty to forty flowers. These are light green with a yellow throat. None of the plants of this genus

can lay claim to much beauty; but this particular species is, perhaps, the sweetest-scented climbing plant in cultivation, one truss being sufficient to fill a whole house with perfume.

The plant generally commences to bloom in May, and continues more or less in beauty during the summer months. It is easily propagated, and even small plants will grow well in peat and loam.—CHARLES ROBERTS, *Dorfold Hall*.

SKELETONISING LEAVES.

If you wish to make a bouquet, the first thing to do is to select the leaves and seed vessels that you intend to use. If you have never tried your hand at this kind of business, it would be better for you to try such leaves as those of the Oak or Maple, for the reason that the veins in these leaves are stronger than in most others, and come out of the bleaching process more perfect than thinner ones.

When you have selected your leaves and seed vessels, brush off any particles of dirt that may possibly cling to them. It is necessary that this should be done in order to insure their perfect whiteness; for if any dust or dirt adheres to them when put to soak, it will be apt to stain them in their long bath, and the stain thus given will be hard to efface.

Take a wide-mouthed jar—one that will admit of putting in and taking out the leaves without cracking or bruising them. Lay in your leaves evenly—the stems all turned one way, to avoid getting them tangled when you take them out.

When you have your jar as full as you wish, pour over them warmed rain water. There should be enough to completely cover them. Let them stand where they will be kept warm. Change the water once a week, at least; every two or three days would be better. Cover with a plate, or something that will exclude all dust. The water should be pure.

In two or three weeks the fleshy part of the leaves will be reduced to pulp, and can be removed with a soft brush. Be careful to brush away every particle of the pulpy matter. When you have them skeletonised, as this part of the work is called, they are ready to put to bleach.

To prepare material for bleaching, take a quarter of a pound of chloride of lime, and put it in some clean vessel with one and a half pint of cold, soft water. Stir briskly, breaking all the lumps. When the lime has settled—and it will not take long for it to do so—the solution may be poured off and bottled for use.

When ready for bleaching, place your skeletonised leaves in a large-mouthed vessel. It is necessary that the mouth of the dish be large enough to admit your hand, as the delicate lace-like leaves break very easily, and should not be bent if it can be avoided. Place the leaves in the vessel, and add enough water to cover them. A tablespoonful of the bleaching solution may then be added to every pint of water. If seed vessels are to be bleached, keep them by themselves, as they are apt to tear the lace-like network of the leaves, and add more of the bleaching solution, as the thick stems are harder to bleach than any other part of a bouquet, and require more chloride to effect this part of the work satisfactorily.

A day will probably be long enough to whiten them completely. Take out one carefully, and you can tell by that when they are sufficiently bleached. When you think they will do, remove them carefully, and lay them in a large dish filled with clear soft water. Wash them carefully, and pour off the water; after which, rinse thoroughly through two or three waters slightly warmed. They must be rinsed free from all the chloride of lime, or they will be apt to change to a dingy yellow.

When you have them washed, place them between sheets of blotting paper to dry. A very short time will suffice for them to dry in. Do not allow them too get too dry and crisp for handling without breaking, before you form them into bouquets. When you can bleach Oak, Maple, Beech, and such leaves well, you can try more delicate ones; and if you are careful in your work, you will succeed in preparing some fine specimens.—E. G. REXFORD.

DESTROYING WIREWORMS.

LET "INFELIX" (see page 395), try a heavy dressing of lime to get rid of the wireworm. I took my present place in October, 1866. Every thing and every place was infested with it. It was no use to attempt to grow Celery—in fact, it was as bad as it could be. I asked questions right and left, but no one could give me a cure. I thought I would try lime. I put, I should think, as nearly as possible three tons per acre. Last year I

had splendid Celery, and my gardener says there is scarcely such a thing as a wireworm to be found in the place. I was also overrun with snails; since putting in the lime I have not 1 per cent. of the number I had before. I may mention that the gardener had been eleven years in the place, and had never known any lime used.—DRAYTON GREEN.

NEW BOOK.

Gleanings from French Gardens. By W. ROBINSON, F.L.S.
London: Frederick Warne & Co.

THIS volume is a *rechauffé* of what the author has written in a series of articles in various journals during the past twelve-month, and which he considers of sufficient importance to be embodied in a collected form for the permanent benefit of British horticulturists. With very few exceptions there is nothing contained in Mr. Robinson's book which has not been treated upon over and over again in the pages of this and other garden journals; so that these "Gleanings" are nothing more than the author's view of certain features of French horticulture, which subjects have all been discussed before; and such operations as are described in the work as being most worthy of adoption, and are suited to our climate, have already been introduced into our garden practice. All that the author has written on Fruit-tree Pruning, Gladiolus Culture, Rose Showing, the Parks and Gardens of Paris, and other minor subjects, have all been made familiar to the public before by other writers, and however interesting they may have been as fugitive pieces in periodical publications, they are not of that importance to require the permanent form in which they now appear. Among his certain features most worthy of adoption, let us take for instance "Mushroom Culture," at page 243, and we ask any ordinary English gardener wherein the French process described by Mr. Robinson differs essentially from that practised in this country:—

"They begin with the preparation of the manure of course, and collect that of the horse for a month or six weeks before they make the beds; this they prepare in some firm spot of the market garden, and take from it all rubbish, particles of wood, and miscellaneous matters; for, say they, the spawn is not fond of these bodies. After sorting it thus, they place it in beds 2 feet thick, or a little more, pressing it with the fork. When this is done the mass or bed is well stamped, then thoroughly watered, and finally again pressed down by stamping. It is then left in that state for eight or ten days, by which time it has begun to ferment. After these eight or ten days the bed ought to be turned well over and re-made on the same place, care being taken to place the manure that was near the sides of the first-made bed towards the centre in the turning and re-making; then they leave the mass for another ten days or so, at the end of which time the manure is about in proper condition for making the beds that are to bear the Mushrooms. If they do not find the stuff 'sweet,' unctuous, and of a bluish-white colour in the interior, they do not expect much success; but by carrying out the foregoing simple directions there is little chance of having it otherwise. Then they make the little ridge-shaped beds—about 20 inches wide, and the same in height—formed like 'the back of an ass,' and placed in parallel lines, at a distance of 20 inches one from the other. The manure is made into close little beds gradually and carefully, the man pressing it down well with the fork, so as to give the whole mass a firm close-fitting texture, so to speak, and gradually narrowing as he builds till his little ridges are finished. Of course the length of those ridges will be determined by the wants of the grower; in a market garden they may extend over and cover a considerable extent. The beds once made, the manure soon begins to warm again, but does not become unwholesomely hot for the spread of the blanc or spawn. When the beds have been made some days the cultivator spawns them, having of course ascertained beforehand that the heat is genial and suitable. Generally the spawn is inserted, the holes being made in one line around the bed, within a few inches of the base, and at about 13 inches apart in the line. Some cultivators insert two lines, the second about 7 inches above the first. In doing so, it would of course be well to make the holes for the spawn in an alternate manner. The spawn is inserted in bits about the size of three fingers, and then the manure is closed-in over and pressed firmly around it. This done, the beds are covered with about 6 inches of clean litter. Ten or twelve days afterwards they visit the beds to see if the spawn has taken well. When they see the white filaments spreading in the bed they know that the spawn has taken, and that it is good. If they do not see that it has begun to spread, they do not leave the bed alone, as too many do amongst ourselves, but take the spawn they suppose to be bad and replace it with better. But, using good spawn and being practised hands at the work, they rarely fail in this particular; and when the spawn is seen spreading well through the bed, then, and not before, they cover the beds with fresh sweet soil to the depth of about an inch or so."

It is evident, from the perusal of this book, and as our

readers will judge from the above extract, that Mr. Robinson is not himself sufficiently instructed to enable him to instruct others, else he would not have offered this as a feature of French gardening worthy of our adoption. Like most young travellers who visit strange countries for the first time, everything he saw in France with which he himself was not familiar was noted down as new, and the self-confident tone with which he assailed the criticism of practical men of greater experience who commented on the subjects upon which he wrote gave for a time an importance to them which they would never otherwise have possessed, and which has now entirely subsided.

There is one chapter for which we must give Mr. Robinson credit, and that is the first, on "Subtropical Gardening," which has more freshness about it than all the rest of the book besides.

There are one or two errors which Mr. Robinson should correct in the next edition. In every case he calls M. Jamin, of Bourg-la-Reine, "Jamain," M. Jamin being of an entirely different family, though also a nurseryman; and he calls M. Rose Charneux, M. Charmeaux. These are, of course, trivial mistakes, but they are apt to suggest that the other contents of the book have been got together with a similar want of regard to perfect accuracy.

ROYAL BOTANIC SOCIETY'S SHOW.

MAY 27TH AND 28TH.

THE grand features of the Exhibition were the Roses exhibited by Mr. William Paul, and Mr. Turner's magnificent Azaleas which were the admiration of every one, and when viewed from the opposite side of the Exhibition they looked most imposing and extremely beautiful. The only fault I could detect was the want of a few more green leaves to relieve the glowing masses of colour produced by this splendid group of plants. I hear they have passed into the hands of a private grower, Mr. Turner having sold them.

The next grand feature of the Exhibition was the magnificent Pelargoniums exhibited by Mr. Fraser, of the Lea Bridge Road. They were certainly the best-grown lot of plants ever exhibited, the only fault noticeable in the collection of Fancy kinds was the want of one or two lighter shades of colour. Most of the varieties were of dark shades. In the class for nine large-flowered varieties the colours were more evenly balanced. In both of the above classes no difficulty could have presented itself to the Judges in awarding the first prize, for the plants were as much superior to all other collections as Mr. Turner's Azaleas were to all other exhibitions in that class.

The Orchids were also good and numerous, likewise the stove and greenhouse plants. Cape Heaths were also exhibited by Mr. Peed and Messrs. Jackson & Sons. It is a pity that this fine class of plants should have ceased to create the interest they did in former years. When Mr. Smith, of Norwood, produced his finely-grown plants they were deservedly considered the gems of every exhibition they were shown in. It is to be hoped Heaths will again regain their proper position at our exhibitions.

Mr. James, gardener to W. Watson, Esq., Isleworth, staged the most marvellous collection of Calceolarias I have seen. They were perfect masses of bloom, averaging about 2 feet 6 inches or 3 feet through, and the most perfectly-grown plants I ever saw exhibited. Their names were—Master Parrell, Picturatum, Prince of Wales, Gratitude, and Conqueror.

The eight greenhouse Azaleas staged by Mr. C. Penny, gardener to H. H. Gibbs, Esq., Regent's Park, were well worthy the highest award. They were well grown and exhibited in good condition. In several of the plants the fresh green foliage was pleasingly interspersed with the flowers, a circumstance which gave them a much fresher and more agreeable appearance, and a finish not to be seen in any other collection in the Exhibition. This style of exhibiting them should be more encouraged, and would do away with the monotonous appearance presented by such immense masses of colour, without the natural proportion of green with which Nature when left to herself accompanies her floral productions.

Fine collections of Ferns were exhibited by Mr. B. S. Williams, of Holloway, and others. These gave a fine character to any exhibition, and wonderfully relieve the eye.

Amongst the novelties exhibited was a pretty white bedding Pelargonium named White Stella. It appeared to have all the good qualities which Beaton's famous Stella possesses, but instead of producing a crimson flower it is pure white. I think this will become a valuable bedding plant. It was exhibited by Mr. Aldred, of 22, Bridge Street, Maida Vale, together with several very promising Tricolor-leaved and other Pelargoniums. Mr. Mann, of Brentwood, again exhibited a splendid box of Zonal Pelargonium Lord Derby. This is, without doubt, the finest Scarlet Pelargonium ever raised, and if it retain its fine character when bedded out, will indeed be a most valuable acquisition to the flower garden. I strongly recommend all our readers interested in this class of plants to at once procure Lord Derby.

Near Mr. Mann's beautiful box of Lord Derby was a pretty col-

location of hardy, herbaceous, and alpine plants exhibited by Mr. Ware, of Hale Farm Nurseries, Tottenham. Amongst these I noted the following as likely to prove useful for bedding purposes—*Diplotaxis tenuifolia variegata*, having a pretty, white, variegated *Chrysanthemum*-like leaf, deeply jagged, a bed of this edged with blue *Lobelia* or scarlet *Verbena* would have a fine effect, or a bed planted alternately with this and the beautiful new *Colons Marshallii* would produce one of the grandest effects ever seen in any bedding arrangement. Another pretty variegated plant in this collection, and likely to prove useful on account of its neat habit, is *Agropodium podagraria variegata*. Messrs. E. G. Henderson exhibited some pretty plants suitable for bedding purposes. Foremost amongst these is *Centaurea ragusina compacta*, certainly the finest of all the frosted-silver plants for bedding purposes. This if used as an edging to a bed of *Colons Marshallii* would produce a fine effect. I can conceive nothing more beautiful than a large bed planted as follows, the bed to be surrounded with grass:—Supposing the bed to be 12 feet across, I would plant the centre with *Colons Marshallii*. This should occupy 5 feet. Next to it I would plant a ring 2 feet 6 inches wide of *Centaurea ragusina compacta*; next to this a ring of *Lobelia speciosa*, 2 feet 6 inches wide, finishing with a 2-feet edging of the pretty golden *Pyrethrum Golden Feather*, or Little Golden *Christine Pelargonium*—either would do—next the grass. The latter would, however, have the finer effect as it produces immense numbers of pretty pink flowers borne well above its neat yellow foliage. These would harmonise beautifully with the bright blue *Lobelia*, the green grass surrounding, and the neat yellow foliage. Or, in lieu of this, the beautiful golden *Colons Telfordi aurea* might be used with good effect. This will undoubtedly prove one of the finest yellow-foliaged bedding plants in cultivation. Visitors to Battersea Park during the summer will have an opportunity of judging for themselves of the effect produced by the two beautiful *Colons*—*Telfordi aurea* and *Marshallii*. I feel sure a bed planted according to the arrangement I have suggested above would have an extremely fine effect.

The mention of the two *Colons* above reminds me that most of the varieties lately sold by the Royal Horticultural Society were exhibited on this occasion. Mr. W. Bull also exhibited his collection of varieties raised by himself. From the kinds exhibited a good selection may be made, and this is the order in which they stand in my estimation. For cultivating in pots for conservatory decoration—1, *Colons Marshallii*; 2, *C. Bausei*; 3, *C. Berkeleyi*; 4, *C. Telfordi aurea*; 5, *Gem*; 6, *Elegant*. For bedding purposes—1, *C. Marshallii*; 2, *C. Telfordi aurea*, and 3, *C. Berkeleyi*. It is generally admitted that *C. Marshallii* is the best of the whole series for all purposes. If I make a wrong assertion in thus placing *Marshallii* I am open to correction, and willing to cancel the opinion I have formed of its merits. Having made this selection of the varieties exhibited up to the present time, I think all the others may be easily dispensed with. The above six have all received first-class certificates, and several of them have been awarded this distinction by three societies.

A very handsome plant was exhibited in Mr. Bull's collection under the name of *Coprosma Baueriana variegata*. I have great hope of this making a first-class bedding plant; it has beautiful glossy green leaves, which are edged with a deep band of creamy white, they are of great substance, and the plant has an erect or stately style of growth; I have booked this as first-rate. It would have a fine effect if planted with the dark-foliaged *Colons*. Mr. Bull also exhibited some pretty *Petunias*, suitable for bedding purposes.

Mr. W. Paul exhibited several good bedding plants, amongst these a Gold and Silver Tricolor-leaved *Pelargonium*, named *Prince Silverwings*, with a *Stella* habit and style of growth. This is a very pretty and useful plant. His *Cottington*, *Scarlet*, or *Double Tom Thumb*, I think will prove most useful for bedding purposes. It is a most profuse-flowering variety, and the flowers appear to remain on the plant a long time in perfection; they are semi-double. A basketful of a very pretty neat bedding hybrid *Pelargonium*, in the way of *Shrubland Pet*, also came from Mr. W. Paul; this was named *Little Gem*.

In the collection of Messrs. J. Veitch & Sons there were gems in the way of stove plants, including some of the *Colons* named above, the curious and beautiful *Begonia boliviensis*, some new *Alocasias*, and curious double-flowered *Gloxinias*. Messrs. Carter & Co. exhibited some fine Tricolor-leaved *Pelargoniums*. Their *Prince of Wales* promises to be a very great acquisition, also Mrs. Dunnott. The same firm likewise exhibited some fine *Echeverias*; one named *metallica*, is remarkably fine, having large thick leaves of a metallic colour. This will also prove a very handsome plant for bedding purposes. *Echeveria sanguinea*, also exhibited by the Messrs. Carter, is a fine bedding plant.

Messrs. Dolson & Son, of Isleworth, exhibited a fine lot of their splendid *Pelargonium Magnet*. This I think will prove a splendid market plant. Every plant was as even as if it had been turned out of a mould. Space will not permit me to refer to the curious hybrid Ivy-leaved *Pelargoniums* exhibited by Mr. Wimsitt; these must form the subject of another paper.—J. WILLS, F.R.H.S.

NORWICH HORTICULTURAL AND FLORAL FÊTE.—This, which will be held at Norwich from the 19th to the 22nd of August, during the visit there of the British Association for the Ad-

vancement of Science, will be on a very liberal scale. As an example, for twelve stove and greenhouse plants the first prize is £10; the second, £7 10s.; and the third, £5.

ROYAL HORTICULTURAL SOCIETY'S SUMMER SHOW.—JUNE 2ND TO 5TH.

The glories of Chiswick were revived on Tuesday last in the magnificent Show of the Royal Horticultural Society at South Kensington, which, for the splendour of the plants, the unusually propitious weather, and the brilliancy of the company, has not been surpassed. Rival exhibitions have for many years bid high for popular favour, and for a time shared the honours of horticulture with the old Society; but the tide is again on the turn, and the prestige which by precedence and prescription belong to the Society, but which was lost for a time, has again returned, and horticulturists find in its regenerate state all the attractions of a first love. Notwithstanding the diversion of the great Show at Manchester, to which many of the plants of our great metropolitan exhibitors were attracted, there was such a profusion in the conservatory and covered arcades of South Kensington, that space could hardly be found to accommodate them, a refuge for some having been found in the open arcades. What struck thoughtful observers on Tuesday was the sad want the Society has to contend with in not having a suitable place wherein to hold the exhibitions. Grand as the Show of Tuesday was, its finest features and the capabilities of the material of which it was composed to form a splendid effect, were entirely lost through being confined to those dark one-sided arcades. The conservatory was all that could be desired, and all was done that could be done with it under present arrangements; but if that Exhibition had been held in a place suitable for the purpose, it would have made a display such as has not been seen since the great International Show of 1866. Contrast the rigid formality of this with Messrs. Waterer & Godfrey's glorious exhibition of *Rhododendrons* in the great tent, and it will be seen on what side the advantage lies. The Council has, with Mr. Gibson's assistance, made a most successful alteration in the arrangement of the ground in this tent, and if they could be persuaded to erect somewhere in the garden a permanent structure adapted to the present improved style of plant exhibitions, not only would they secure the support of all the leading exhibitors, to whom dark arcades and similar inconvenient places are peculiarly discouraging, but they would find that all the circumstances attending the exhibitions would tend to make them far more attractive and profitable. There is a dead dullness about the lower end of the garden, where all sorts of ineffective attempts at "bedding" have been carried on, which might be much more usefully employed were some such structure erected there, and if connected with the eastern and western arcades, would form a dry and well-sheltered promenade all round the garden. Without depreciating the efforts of other societies and public bodies who have established rival exhibitions, it is not to be forgotten that though the power of numbers has not always of late years been with the Society, it has continued to preserve so much of its influence and prestige as have enabled it through great difficulties to maintain the first position, and always to be regarded as the nucleus round which all purely horticultural matters instinctively centre. All that is now wanting is a proper place in which the Society can exhibit the power of its influence.

THIS, the best display which the Society has yet held at Kensington commenced on Tuesday last, and will continue till Friday evening. Its extent will be judged from the facts that prizes were offered in the schedule in nearly seventy classes, that nearly all of these were

taken, and that not without in most cases severe competition. The subjects thus brought together extend from the north-east entrance to the eastern arcade, and through the conservatory, where they are closely packed on a double row of staging, to a point far down in the western arcade, and for their great variety and general excellence they are such as are rarely equalled. Besides the other attractions of the Show, there is in Captain Fowke's immense tent, the grand exhibition of Rhododendrons by Messrs. Water & Godfrey which is certainly the finest display of the kind that has ever been seen in this country. Altogether the great Summer Flower Show is the greatest success of the season in a horticultural point of view, and we think it will also be a success, judging from the vast assemblage of visitors on the first and second days.

In Class I, for nine Azaleas, Mrs. Glendinning & Sons are first with magnificent plants of Madame Mueliez with large white flowers beautifully flaked and dotted with purple, Eulalie, Variegata, Lateritia, Prince Albert Victor, Gledstanesii, Petuniflora, Purpurea magnifica, and Gem, the last two, though fine in colour, being smaller plants. Mr. Carson, gardener to W. R. G. Farmer, Esq., Nonsuch Park, Cheam, is second with large splendid specimens, very even in size and training, of Sir C. Napier, salmon, Triumphans, the yellow Sinensis, Holfordii, very showy rose crimson, Broughtonii, densely covered with flowers, Murayana, Exquisite, Formosa, and Apollo, the last a dazzling mass of scarlet flowers. Mr. Turner is third with Etoile de Gand, Iveryana, still one of the most effective of the white kinds, Glory of Sunninghill, Gledstanesii, small plants of Cheloni, Mars, and Leopold I, with two others. In the nurserymen's class, however, Mr. Turner takes the first prize with six magnificent plants standing 7 or 8 feet high, consisting of Sir C. Napier, Optima, Gledstanesii, Madame Mueliez, Variegata, and Brilliant, the scarlet flowers of which are beautifully interspersed with a few of the leaves. Mr. Williams comes second. In the corresponding class for amateurs Mr. Penny, gardener to H. H. Gibbs, Esq., Regent's Park, takes the first position with splendid examples of Brilliant, Cheloni, Iveryana, Gem, and Sir C. Napier. Mr. Carson, who is second, has a fine plant of Juliana, about 4 feet high, and Model is also fine; and Mr. Wilkie, Oak Lodge, Kensington, is third. Of plants in pots not exceeding 12 inches in diameter, two fine collections are furnished, the one by Messrs. Ivery, the other by Mr. Turner, and which respectively receive first and second prizes. Messrs. Ivery's plants are neatly grown, finely bloomed pyramids, standing from 3 to 4 feet high. Duchesse de Nassau is especially fine; the others are Gem, President, Cheloni, Extranei, Criterion, Charles Enke, Duc d'Arenberg, Variegata superba. Mr. Turner sends Duc de Brabant, Flower of the Day, Flag of Truce, Elegantissima, and some of those already named, the whole being in fine condition, and several of them wonderful specimens for such small pots.

Of Roses in pots Mr. William Paul is the only exhibitor, and takes first prizes in all the classes in which he exhibits—namely, for nine plants in 13-inch pots, for twelve in 10-inch pots, and for six new kinds sent out in 1865 and 1866. Juno, Coupe d'Hébe, and Lelia in the first-named class are remarkably fine. His six new kinds consist of Black Prince, Fisher Holmes, Mademoiselle Marie Raby, Rose Perfection, Camille Bernardin, and Prince de Portia; but though well-bloomed plants, when we saw them they had suffered, notwithstanding the awning, from the sun and heated atmosphere of the conservatory, which was densely crowded on the afternoon of the opening day of the Show. Mr. W. Paul's group of twelve also consists of nicely bloomed plants. Of cut blooms twelve fine boxbills are shown by Messrs. Paul and Son and ten by Mr. Turner, who receive extra prizes; and Messrs. Lee, of Hammersmith, send some charming blooms of new kinds.

Pelargoniums of all kinds are exhibited in overpowering numbers, and of a perfection which is but rarely approached. The nine plants from Mr. Fraser, of Lea Bridge Road, are especially remarkable for their size and profusion of bloom, particularly Lilacina and Sanspareil. The others, but little inferior to them, are Excelsior, Desdemona, Ariel, Caractacus, Leander, Lord Clyde, and Conqueror. Mr. Turner is second with Pericles, Lord Clyde, Fairest of the Fair, Mary Hoyle, Desdemona, Exhibitor, Fair Rosamond, Congress, and John Hoyle, all of which are also large and fine plants, though not equal to Mr. Fraser's. Mrs. Dobson & Sons, of Isleworth, are third. For six kinds Mr. Fraser is again first with Lilacina, Candidate, Conflagration, Pericles, Diana, and Fair Rosamond. Among amateurs Mr. Nye, gardener to E. Foster, Esq., Clewer Manor, is first with very fine examples of Empress Eugénie, Conqueror, Miss Burdett Coutts, Desdemona, Lord Chancellor, and Fair Rosamond. Mr. Ward, gardener to F. G. Wilkins, Esq., Leyton, who is second, also has plants in very fine bloom.

Of Fancy Pelargoniums, always so beautiful, the finest six in the nurserymen's class come from Mr. Fraser, who exhibits plants about 3 feet across and remarkably fresh, consisting of Ellen Beck, Delicatum, Clara Novello, Roi des Fantaisies, Arabella Goddard, and Lucy. Mr. Turner is second with smaller plants, very compactly grown, and well bloomed. Among these Tormentor, dark crimson fringed with rose and having a light eye, is very attractive. Mrs. Dobson & Sons are third. In the amateurs' class, Mr. Windsor, gardener to J. R. Ravenhill, Esq., is the only exhibitor, and takes a first prize with medium-sized plants of Undine, Mrs. Ford, Delicatum, Madame Sainton Dolby, Roi des Fantaisies, and Multiflorum.

Of Zonal Pelargoniums there are several fine collections which

constitute a very attractive feature of the Exhibition. The best six (Nosegay and Variegated kinds excepted), come from Mr. Catlin, gardener to Mrs. Lermite, Finchley, and consist of large, finely-bloomed specimens of M. Rendatler, Scarlet Globe, Clipper, Madame Vancher, Eugénie Mezard, and Excellent. Mr. Windsor, who is second, sends Virgo Marie, M. Rendatler, Great Eastern, and Louis Roseler. Mr. Weston, gardener to D. Martineau, Esq., is third. In the class for nurserymen, Mr. Fraser is first with splendid plants of Rose Rendatler, Eugénie Mezard, Jules César, Clipper, remarkably fine; Leonidas, orange scarlet; and Louis Venillot.

For the best specimen Pelargonium of any kind, Mr. Fraser takes the first prize with a very large plant of Desdemona; Mr. Nye being second with Pericles, about 3 feet in diameter; and Mr. Turner, third, with a fine plant of Exhibitor.

Fuchsias are always very attractive when well grown, but are not numerous shown, still those staged are generally in very good bloom. Mr. G. Osborn, Finchley, has the best four in the nurserymen's class. These are Vainqueur de Puebla with a double white corolla, very fine; Conspecta, single white corolla; Rose of Castille, and Prince of Orange. Messrs. August & Wright, Haverstock Hill, are second with Roderick Dhu, scarlet sepals and violet blue corolla; Puritani, carmine sepals, white corolla; Catherine Parr, white sepals, salmon rose corolla; and Enoch Arden, very large, scarlet sepals, blue and red corolla. In the amateurs' class, Mr. Weston, gardener to D. Martineau, Esq., is first with well-bloomed pyramidal plants of Comte Cavour and Universal, dark; and of light kinds, Rose of Castille and Annie. Mr. Filce is second; and Mr. Foreman, gardener, Denmark Hill, and Mr. August, Bedington, equal third. The last-named also sends the best specimen plant, and Mr. Osborn the second best.

Of herbaceous Calceolarias, Mr. James as usual sends splendid examples; and of Lilium auratum good pots come from Mr. Bull and Mr. Turner. The latter has also the best twelve early Pinks. Scarlet Gem, Helen, Devise, Ernest, and Rubens, are very good. Mr. August takes the second prize for Pinks; and Mr. Turner, Notting Hill, the third.

Orchids follow next in the order of the classes, and of these Mr. Penny has a very fine collection of twelve. Among them are Cattleya Mossiae, remarkably fine, the beautiful Odontoglossum Alexandræ with three spikes, Cypripedium villosum, Lycaste Skinneri superba, Cypripedium barbatum superlunum, and Dendrobium macrophyllum giganteum, which, however fine, has a most offensive odour. Mr. Peed, who is second, has among others Dendrobium clavatum, a handsome orange kind with a dark spot, Cattleya Mossiae with unusually large flowers, good Acrides, and the showy Epidendrum vitellinum. In the nurserymen's class for ten Mr. Williams is the only exhibitor, and takes the first prize with a collection in which we particularly noticed Acrides Larpenae, odoratum, and Lindleyanum. Saccolabium guttatum Holfordii, fine Cypripediums, Dendrobium nobile, Cattleya Mossiae. For six Orchids Mr. Penny is again first, and has the showy new Thunia Bensoniae, Oncidium sarcodes, one of the handsomest of Orchids, the Foxhrush Acrides, Odontoglossum Pescatorei, and a pale variety of Lycaste Skinneri. Mr. Burnett, gardener to W. Terry, Esq., Fulham, is second, and Mr. Young, Leigh Park, Havant, third. Mr. Bull also takes a first prize for a collection of six; and for the best specimen Orchid Mr. Penny is first with Cattleya Warneri with eight large, bi-hyly coloured flowers; and Mr. May second with Acrides Lindleyanum with two branching spikes.

Stove and Greenhouse plants are shown so numerous that our remarks on these must be brief, especially as among these plants but few fresh subjects of exhibition have been introduced of late years. The best collection of twelve is that from Mr. Peed, gardener to Mrs. Tredwell, Lower Norwood, and it includes a very large bush of Erica Cavendishii; E. ventricosa magnifica, likewise large, and very bright and fresh in colour; two large Eriostemons, Acrophylllum venosum, Azaleas, and Dracophyllum gracile. Mr. May, gardener to T. P. W. Butt, Esq., Arle Court, Cheltenham, is second, and has in his collection Allamanda grandiflora; Erica jasminiflora alba, with charming white flowers; Phænoecoma prolifera Barnesii; Ixora coccinea, with about a score heads of bloom, some of which are remarkably fine; Ixora salicifolia, not well furnished at the base, but producing fine heads of its orange flowers; a very neat well-bloomed plant of Stephanotis floribunda; Azaleas, and the large-flowered showy Franciscea calycina. Mr. Wilkie is third with Azaleas, Ixoras, a Heath, a well-grown bushy Genetyllis fuchsoides, and other plants. In the nurserymen's class Mrs. Glendinning & Sons are first with a nice collection, Mr. Williams second, and Mr. Tanton, Epsom, third. In the amateurs' class for six plants Mr. Peed is first with fine specimens of Clerodendron Balfourii, very showy and effective by its white and crimson flowers; Dracophyllum gracile, 4 feet across; Ixora coccinea, splendid; Franciscea calycina, and Phænoecoma prolifera Barnesii. Mr. Burnett is second with well-grown neat plants of Rhynchospermum jasmoides, Stephanotis floribunda, Aphelaxis macrantha rosea, and Acrophylllum venosum. Mr. Wilkie is third, and an extra prize goes to Mr. May. Mr. Ward, gardener to F. G. Wilkins, Esq., sends a remarkably fine Dracophyllum gracile, Clerodendron Balfourii in fine condition, Genetyllis tulipifera, and other well-grown plants; and Mr. Carr, gardener to P. L. Hinds, Esq., Byfleet, a very fine example of Rhynchospermum jasmoides. The first prize for the best specimen stove and greenhouse plant goes to Mr. Peed for Acrophylllum venosum, 4 feet high and little less in diameter; Mr. Wilkie being second with

Dipladenia amabilis, well grown, but with only six flowers; and Mr. May third with *Ixora coccinea*.

Heaths, though there are many very well-grown plants, are not remarkable. The best six come from Mr. Peed, and among them are *Depressa*, *Candolleana*, *Eximia*, and *Massoni*, all of them very good specimens. Mr. Ward, who is second, has good examples of *Fairrieana*, *candidissima*, *Easoniana*, *Massoni major*, *Depressa*, and *Tricolor elegans*. Messrs. F. & A. Smith are third, and Mr. Williams takes an extra prize.

The only specimen standard *Rhododendron* shown is one from Mr. Wilkie, which, however, is not remarkable; and to complete the section for flowering plants there is a class for twelve *Amaryllids*, in which Mr. Williams is the only prizetaker. One of the varieties he exhibits, named *Graviana*, is a fine scarlet with a white band; and of the others *Ackermannia pulcherrima*, a well-known kind, and *Eldorado*, light, but rather narrow in the petal, are the most showy.

We now come to the plants with ornamental foliage, and nobler specimens than some of these, except at the London International Horticultural Exhibition of 1866, we never remember to have seen. The best collection of nine comes from Mr. Fairbairn, gardener to the Duke of Northumberland, Sion. Notable among these plants are *Anthurium acule*, with leaves 4 feet long and 14 inches across at the widest part; *Alcacia metallica*; *Alcacia zebrina*, with very conspicuously marked leafstalks; and *Alcacia macrorrhiza variegata*, with its broad foliage very extensively splashed with white, sometimes one-half the blade being so occupied. He has besides a very fine *Lantana borbonica* and *Anthurium magnificum*. Mr. Taylor, gardener to J. Yates, Esq., Highgate, who is second, has also fine specimens, among which is *Cycas circinalis*, which has a very graceful appearance when, as here, it is viewed from a lower level, *Sabal Blackburniana*, and *Dion edule*. He has, besides, *Encephalartos cafræ*, *Rhopala corcovadense*, and *Curenlago recurvata*, an *Amaryllidacean* plant with grass-green ribbed leaves. Mr. Williams, who is third, has fine *Crotons*, especially *C. angustifolium*. *Anthurium regale* with leaves 2 feet long by 15 inches broad, *Dracænas*, and other plants already named. Mr. Barley, Albert Nursery, Bayswater, also sends a good collection. For collections of six Mr. Taylor, Mr. May, Mr. Fairbairn, and Mr. Young take prizes in the order in which they are named; and they send some fine specimens of *Alcacias*, *Crotons*, *Pandanads*, *Palms*, *Theophrastas*, *Dracænas*, *Marantas*, the Rush-like *Littæa jancea*, *Anthuriams*, and *Caladiams*.

To *Caladiums*, however, a class is specially assigned, in which are exhibited some remarkably fine specimens of *argyrites*, *bicolor splendens*, *Belleymei*, *Houllettii*, *Cannarii*, *Chantini*, *Wightii*, &c., by Messrs. Smee, Fairbairn, and Wilkie. *Anthuriams* likewise have a class, in which Mr. Williams takes a first prize with *magnificum*, *acule*, and an unnamed kind with dark green leaves.

Of *Yuccas*, fine pairs are shown by Mr. Bull and Mr. Williams, the latter having tall specimens of the variegated *Aloe-leaved* kind, and he also takes first prizes for *Agaves*, a pair of *Dracæna lineata*, standing about 10 feet in height, and for noble examples of *Dicksonia antarctica*, the trunk of one of which cannot be less than 12 feet in height and 18 inches diameter.

Ferns, stove, greenhouse, and hardy, are very numerous shown, so much so that it would be a hopeless task to attempt to particularise more than a few as being fine. Such are *Cibotium princeps* and *Schiede*, *Cyathea Smithii*, *Gleichenias*, *Cyathea delbata*, *Dicksonia antarctica*, *Todea africana*, *Pteris tricolor* and *argyrea*, *Lomaria gibba*, *Marattia elegans*, and *Alsophila contaminans*, spreading 12 feet across. The principal prizetakers are Mr. Williams, Mr. Taylor, Mr. Young, Mr. May, Mr. Wilkie; and for hardy Ferns, Messrs. Ivory and Mr. Salter, who each show beautiful collections.

In the section for plants shown for their foliage, are *Variegated Zonal Pelargoniums*, and of these Mr. Turner and Messrs. F. & A. Smith have equal first prizes for fine collections. The former has *Lady Collum*, Mrs. Turner, *Sophia Damaresque*, *Lady of Shallot*, *Princess of Wales*, and *May Queen*, the last named only having white-edged leaves. Messrs. F. & A. Smith have *Meteor*, *Banshee*, *L'Empereur*, *Miss Burdett Coutts*, exceedingly fine, *Exquisite*, and *Sunray*. Mr. James is third. The new plants are very numerous and interesting, but as many of them have been already described in these pages, even if space permitted it would be of little utility to do more than mention them. Messrs. Veitch take the first prize for the best six in or out of flower, with *Alcacia Jenningsii*, *Begonia boliviensis*, *Croton tricolor*, a green-leaved kind with a yellow band by the sides of the midrib, and coral-coloured stalks, *Dracæna Cheloni* and *regina*, and *Thaunia Bensoniæ*. Mr. Bull is second with *Coprosma Baueriana variegata* referred to in another column, *Maranta virginialis* with silvery bands, *Carex recurvata variegata* broadly striped with cream colour, *Dalechampia Roeziana rosea*, *Encephalartos gracilis*, and *Cibotium regale*. Mr. Williams also sends a collection.

For a new plant shown for the first time in flower, Mr. Bull is first with *Lasiandra macrantha* with fine, large, violet flowers; and Messrs. Veitch second, with a *Rhododendron* with small yellow flowers and narrow leaves. For a new plant not yet in commerce, Mr. Cross, gardener to Lady Ashburnton, is first with *Actinopteris radiata* with very small, semicircular, fan-like leaves; and Mr. Bull second with his *Lasiandra*. For seedling florists' flowers and garden varieties several certificates were awarded, which will be found in the Floral Committee report which is appended.

Miscellaneous plants are so numerous that we cannot particularise much. Mr. W. Paul sends a very interesting collection of *Ivies*, *Aucubas*, *Ligustrum ovalifolium variegatum* with beautiful yellow-variegated foliage; *Ligustrum coriaceum* with dark green leaves of great substance, very unlike those of an ordinary Privet; *Knonymuses*, a beautiful golden-leaved Elm, *Pelargoniums*, &c. Mr. Parsons, gardener to R. Attenborough, Esq., of Acton Green, has some beautiful pans of *Lycopods* and cones of the same 2½ feet in height, grown on peat and wire framework, and which are very fine examples of what can be done in this way. Near these Mr. Earley exhibits a fine *Lycopodium scandens*, about 12 feet high. Messrs. Veitch and Mr. Bull have large collections of new plants, among which are several remarkably fine specimens of these. Mr. Burley has a collection of *Palms*; Messrs. Lee a mixed collection chiefly of new plants; and Messrs. Osborn the *Variegated New Zealand Flax*, the scarlet-flowered *Gesnera Donckelaarii*, *Dasylicion acrotichium*, &c.; Mr. Salter, *Promies*, *Pyrethrums*, succulents, and hardy fine-foliaged plants; Mr. Ware fine collections of herbaceous plants; and Messrs. Carter Coleraces and *Variegated Zonal Pelargoniums*, of which Prince of Wales well maintains its character as a splendid variety. Mr. Wimssett also sends *Coleus Telfordi aurea*, *Marshalli*, &c. In addition, Messrs. Downie, Laird, & Laing, and Mr. Hooper, of Bath, send stands of *Pansies*; and Mr. Turner, *Pinks*. For the awards to these and other subjects we must refer the reader to the official prize list.

FRUIT.

The show of Fruit is not large, but what is shown is very good. Some very good *Pine Apples* are exhibited, the best being a *Queen* from Mr. Williamson, Whitehaven Castle. Mr. Middleton, gardener to Sir W. Watkin Wynne, Wynnistay, is second. Mr. Neale, gardener to K. Cartwright, Esq., Banbury, third. The best dish of *Black Grapes* comes from Mr. Bannerman, Blithfield, who has large beautifully coloured bunches of *Black Hamburgh*. Mr. Sage, gardener to Earl Brownlow, Ashridge, is second with large and fine bunches of the same kind, and jet black. Mr. Aedy, Lee, Kent, is third. Mr. Standish, of Ascot, is first in the class for white *Grapes* with very well-ripened Muscats for this time of year; Mr. Kettlewell, Potter's Bar, being second with *White Frontignan*, and Mr. Osborn, Finchley, third with *Buckland Sweetwater*, small, but well-ripened bunches of which also come from Mr. Bannerman. Of *Peaches*, *Royal George*, very fine, from Mr. Sage, gardener to Earl Brownlow, Ashridge, are first; and the same kind from Mr. Lynn, gardener to Lord Boston, Hedsor, second, Mr. Tegg being third with *Bellegarde*. Of *Nectarines*, the best are *Violette Hative* from Mr. Lynn, which are very large; Mr. Gardener, Ealington Park, is second, and Mr. Cadger, Luton Hoo Park, third, with *Erluge*, very highly coloured. The best dish of *Figs* is *Brown Turkey*, from Mr. Fairbairn, Sion, and Mr. Miles, gardener to Lord Carrington, Wrentham Abbey Gardens, is next. For *Cherries* Mr. Miles is first with *Black Tartarian*, remarkably fine, Mr. Tillery being second, and Mr. Lynn third.

In *Strawberries* Mr. Douglas, gardener to F. Whitburn, Esq., Loxford Hall, Ilford, is first with *British Queen*, very fine, Mr. Young being second, and Mr. Fairbairn, Sion, has a third prize; fine dishes of Dr. Hogg and Sir C. Napier are also shown. The prizes for the best *Green-fleshed Melons* went to Mr. Young for *Bailey's Eclipse*, and Mr. Mackay for *Golden Perfection*; Mr. Whiting and Mr. Cadger taking those for *Scarlet-fleshed* kinds, the latter with *Scarlet Gem*.

Mr. Middleton, and A. Smee, Esq., Wallington, each send a dish of *Apples*, those from the latter being from pot trees; and Mr. Middleton also sends the *Cape Gooseberry*, *Physalis edulis*.

FRUIT COMMITTEE.—On this occasion a special certificate was awarded to Mr. Rivers, of Sawbridgeworth, for a collection of *Cherries*, among which were the following—viz., *Black Hawk*, an American variety, very fine; *Guigne marbré précoce*; *Early Purple Gean*, a large black early variety, which proved the best; *Brandt*; *Noir précoce de Strasse*, a small, black sort; *Empress Eugénie*, a large, pale variety; *Guigne très précoce*; *Rose Hative de Lyon*, large and excellent, rather pale in colour, with firm flesh; *Beile d'Orléans*, pale-coloured, and excellent in flavour; *Werder's Early Black*, and *Bigarreau Jaboulay*. Standish & Co. sent the *Early Ascot Frontignan Grape*, of which the bunch is medium-sized; the berries middle-sized, greenish yellow, oval, with a *Frontignan* flavour resembling that of *Frontignan Ottone*. It appears to be a very good early Grape, but the consideration of its merits was deferred till there should be a full Committee.

FLORAL COMMITTEE.—At this great Exhibition, although comparatively few certificates were granted, the novelties were very attractive. The following first-class certificates were awarded:—Messrs. Ivory, Dorking, received first-class certificates for two new and distinct hardy Ferns, *Athyrium Filix-femina grandiceps pumila*, and a variety of *Lactuca dilatata*. Messrs. Carter had a first-class certificate for *Coleus Dixii*, one of the Society's hybrids. Mr. Bull exhibited his beautiful new plant *Lasiandra macrantha*, which received a first-class certificate. He likewise had similar awards for hybrid *Coleus Gem* and *Coleus Nonsuch*. Mr. Stone, gardener to J. Day, Esq., had a first-class certificate for a very curious and beautiful *Orchid* *Nanodes Medusa*. Mr. C. Turner, Slough, received first-class certificates for each of the following:—*Nosegay Pelargonium Fire King*, large-flowering *Pelargoniums Heroine* and *Royal Bride*, and *Fancy Pelargonium*.

Marmion. Mr. Mann exhibited five specimens of his Zonal Pelargonium Lord Derby, and several other very fine seedlings; but Lord Derby has brought up the standard of merit so high, that the others could not attain it. Mimas is a beautiful flower, and received a first-class certificate last year. Prince of Wales, a rosy salmon; and The Baron, a bright scarlet Nosegay, were also shown. Mr. Cancell sent two seedling Zonal Pelargoniums, also Verbena Beauty of Kent, but not in condition.

SCIENTIFIC COMMITTEE.—Dr. Thomas Thomson, F.R.S., in the chair. A conversation took place on the nomenclature of plants, arising out of the names given to the seedling varieties of *Coleus* arising in the Society's garden at Chiswick, between C. Verschaffeltii, Veitchii, Gibsoni, and Blumei, in which the custom of giving to varieties names which are usually employed in distinguishing species was deprecated. On the question as to whether either or any of the above were really species though found growing in indigenous localities, Mr. Bentham stated, that the only one he knew to be a species was *C. Blumei*, which he himself had founded.

George Pollock, Esq., sent pieces of the wood of Scotch Fir attacked by an insect, of which specimens were not provided, and which is reported to commit such ravages in his plantations at Bagshot, as to destroy a great amount of timber. The further consideration of the subject was adjourned till the next meeting for more detailed information.

Dr. Gilbert gave notice of a subject which he had placed on the agenda paper, and which he truly stated was one of vast importance both to horticulturists and agriculturists, and that is, the effect which certain manures exercise on different plants in various soils. After giving an outline of the elaborate experiments in which Mr. Lawes and he are engaged on this subject, the consideration of it was referred to the Chemical Sub-Committee, with power to associate some eminent physiological botanists with them. Dr. Gilbert stated in the course of his remarks, that whereas on some soils certain manures caused some plants entirely to disappear, by the encouragement of the growth of others of a totally distinct kind; by a change of the manure the original plants may be restored, and those which displaced them in their turn are supplanted. Dr. Gilbert, however, said, that in all the experiments hitherto instituted, no agent had yet been discovered to remedy the defect in land known to farmers as "clover sickness."

GENERAL MEETING.—G. F. Wilson, Esq. F.R.S., in the chair. This meeting was merely formal, the business being confined to the election of eleven new Fellows, and the admission into union with the Society of the Ryde (Isle of Wight) Horticultural Society.

MESSRS. WATERER & GODFREY'S EXHIBITION OF AMERICAN PLANTS.—To this allusion has already been made; but it would not be just to pass over such a splendid exhibition with a mere casual mention, for it deserves all that can be said in its praise—indeed it is the finest exhibition of what are known as American plants that has ever been witnessed. The entire internal arrangement of the tent has been changed, mounds having been thrown up here, little vallies created there, and the formal character which the planting exhibited in former years has given place to a most picturesque appearance, and when viewed from certain points the scene which the huge masses of brilliantly coloured blossom present is lovely; indeed the most lively imagination would fail to form any conception of its beauty.

Among the finest of the newer kinds to be seen here are Mrs. John Clutton, a remarkably fine white; Charles Bagley, cherry red; Sir T. Sebright, purple with a bronze blotch; H. W. Sargent, with very large trusses of crimson flowers; Caracens, with fine trusses of purplish crimson flowers; H. H. Hume, dark crimson; Stella, pale rose; and Parity, a fine white, with lemon-coloured spots.

LARGE BROCCOLI.

I EXHIBITED two heads last week that must have weighed at least 7 lbs. each, and on May 16th I cut two dozen and a half that averaged 7 lbs. each, many being over 9 lbs., and some few 10 lbs. each, when closely trimmed. I certainly never saw such a lot anywhere else, perfectly white, firm, compact, and circular. The only objection raised was, that the pots were not large enough to cook them.—C. C. E.

MR. JOHN WATERER'S AMERICAN SHOW.—This is held in the Royal Botanic Society's Gardens, Regent's Park, and as usual presents a charming spectacle. The undulations of the ground in the tent, to which we have frequently referred in previous reports, greatly tend to enhance the beauty of the display, which is always one of great merit, and on a very extensive scale, as may be judged from Mr. Waterer's statement that between 2000 and 3000 plants, many of them of the largest size, are employed to produce it.

Among the varieties which are the most recent we noted the following—viz., Mrs. John Penn, rosy crimson, beautifully spotted; Princess Mary of Cambridge, light centre edged with rosy purple, fine both in the truss and the individual flowers; Mrs. Thomas Longman, lively rose; Duchess of Sutherland, white, edged with rosy purple; Lady E. Cathcart, blush, finely spotted; Minnie, white, with orange spots; Michael Waterer, rosy scarlet; La Vivandiere, large snowy white

trusses; and Henry Bohn, rosy crimson. Besides these we might enumerate many more brilliant varieties, and specimens remarkable for their size.

INSECTS.

(Continued from page 387.)

THRIPS.—These long, narrow, active insects, mostly confine their attacks to the under sides of the leaves of plants. The insect whilst young is white, and almost stationary, but when mature is of a bright brownish black, and remarkably active. It is a great plague to the Fern-grower, and equally so in almost all departments under glass. In hot, dry seasons it attacks plants in the open air, but is not general on these. The plants chiefly attacked are those with smooth leaves; the Myrtle, Azalea, Humea, Ferns, Melons, and Cucumbers, are great favourites with it; indeed, there are but few plants which at some time do not suffer more or less from it.

The leaves of the plants on which it has made its appearance are spotted with whitish green, and the spots enlarge with the spread of the insect, the leaves ultimately becoming white, and falling off. It is one of many insects which are in a great measure preventible, being fostered by a close, dry, hot atmosphere, which tends to enfeeble the plant. In a moist, well-ventilated house, plants are mostly proof against the attacks of thrips; but there are periods when it is hardly possible to escape it, as at a time when water and cold cannot be brought into play against it; thus the plants may have arrived at such a stage of growth that water cannot be used as a destructive agent, on account of the greater evil likely to arise from a damp atmosphere. When, however, plants can be syringed, water is the best preventive and remedy, the plants being syringed forcibly with water directed against the under sides of the leaves. The next best course to adopt is to afford no more fire heat than is necessary for the well-being of the plant. Another good way of keeping the insect in check is furnishing air early, and yet not inducing cold currents, or by lack of water causing a stunted, hard growth; and, above all, see that the night temperature is considerably lower than the day, and that the plants are not kept constantly exhaling, but shut up early, and with considerable moisture, especially during the growing season.

Thrips is a very fast-breeding insect, it requires a watchful eye to be kept on the plants liable to its attacks. Whenever a plant exhibits any white specks on the under as well as the upper surface of the leaves, look for the cause of their sickly appearance; and if a long, narrow, black, dark-coloured, or even white insect be found, lose no time in proceeding with the work of extermination, for delay will only allow the enemy to increase its hold, and destroy the foliage, if not the plant itself.

The best remedy for thrips is tobacco. Whenever I find one thrips I do not strive to find its companion, but decide to fill the house with tobacco smoke on the first calm evening, taking care to have the foliage of the plants dry, which is liked by the thrips, and it preserves the plants from being scorched or injured by the fumigation. The house is, of course, shut up closely, and if convenient the glass is covered with mats or canvas, so as to keep in the smoke. The house is filled so full of smoke that a plant cannot be seen from the outside. In the morning the floors, walls, and other surfaces, but not the leaves of the plants, are syringed or sprinkled with water, and the house is kept as close as possible consistently with the safety of the plants. In the evening following the fumigation, the plants are syringed, the water being forcibly directed against the under sides of the leaves, and in the morning this is repeated. In the afternoon the plants are examined, and if any thrips are found, as there assuredly will be if the plants were much infested, fumigation is repeated to the same extent as on the preceding evening but one. Next morning the plants are thoroughly syringed, and again in the evening. This will be found an effectual means of destroying thrips which are hatched, but no amount of fumigation with tobacco will kill the eggs, and in cases of severe or rather continued attacks, eggs will be plentiful, and the insect will appear in a few days as if no means had been taken to ward off its attacks. In such cases I usually syringe the plants with 2 ozs. of soft-soap in a gallon of soft water, applying the liquid especially to the under sides of the leaves, and turning the plant round, it being laid on its side in the first instance. The foliage, stem, and every part of the plant should be thoroughly wetted. It must be borne in mind, that all plants cannot endure the wetting of their foliage with soft-soap solutions, and among these are the Vine, Cucumber, Melon, Pelargonium, Azalea,

Calceolaria, and Humea; but there are some to which soft-soap solutions can be used without injury, as the peach, when the fruit is small, the Myrtle, Camellia, and most plants with smooth leaves.—G. ARBEY.

(To be continued.)

RHODODENDRONS AND THEIR CULTURE.

As this is the time for the lovers of Rhododendrons to be on the alert, a few remarks on the subject may be useful.

Rhododendrons may be cultivated in a variety of ways, and may with care be made objects of the highest interest for decorative purposes both in and out of doors. They are moisture-loving plants, but the water must not stagnate about their roots. They almost adapt themselves to any climate if they are properly cared for, succeeding either in beds or as single specimens. They should have proper drainage afforded them, and with that view the place intended for them should have the soil taken out to the depth of 4 feet, and a foot deep of drainage placed at the bottom. Cover the drainage with litter to prevent it from becoming choked, and fill up with the compost, raising it above the surface to allow for settling. Good peat, if it can be obtained, mixed with fibrous loam will answer for them; but in many places peat cannot be had, therefore other soils have to be used. I have found Rhododendrons succeed well in the following compost—viz., bog earth, leaf mould, and mellow loam in equal parts with a liberal sprinkling of sand. A little well-decomposed cow dung will be of service.

If the Rhododendrons are planted in beds, I prefer these to be drier below than above the surface, for should the season be dry a sort of basin is thus formed to water in, and room is afforded for top-dressing or mulching if such be required. Some people raise mounds or banks for them; but I think that plan is objectionable if it can possibly be avoided, for in dry weather I have known them suffer very much from drought, and in time die altogether. If they are planted on the sides of banks we must leave them to take their chance.

I know of some instances in which Rhododendrons have succeeded in pure loam without any preparation. In some counties, Radnor for instance, Hereford, and other places, I have seen fine specimens of Rhododendrons growing without any preparation of the soil previous to planting, and in Yorkshire too, if I recollect aright, many years ago I saw growing in Dr. Herbert's garden at Spofforth, Yorkshire, Rhododendrons planted in loam, the substratum being granite rock, and at that time they appeared in good health. Those who may have seen the Rhododendrons at Stourhead and other places where they are grown extensively, cannot but admire their diversity of colour and the proportion of their growth. Such sights are well worth a day's journey to see, and would be more so could some of the more brilliant-coloured varieties now to be met with be worked on the already-established plants.

My idea of a bank of Rhododendrons is this:—I would have the plants prepared for the purpose, tall ones for the back, and others of lower growth for the front, thus forming the bank with the plants instead of heaping up the soil, which is often done to the injury of the plants.

I trust ere long to see Rhododendrons much more extensively cultivated than they are at present. I know of no evergreen flowering shrub that presents such a diversity of colours, nor any that has been so much improved in the present generation as the Rhododendron. Nothing can surpass at this season a good selection of the beautiful varieties, exhibiting nearly all shades of colour, from the purest white to the deepest maroon.

Rhododendrons are mostly well adapted to pot culture for in-door decoration, and will bear forcing well in gentle heat, but it is not wise to force the same individual plants successively if it can be possibly avoided, for if this be practised they soon become exhausted. Planted out in a conservatory they afford a magnificent display while in bloom, and if grown in boxes or pots for the same purpose, they can be removed at pleasure when their beauty is over to make room for other occupants.

The following are a few species and varieties of this noble race that answer well for pot culture—viz., Ciliatum, a splendid white, sometimes tinged with rose, and which when gently forced (and it bears forcing well), is one of the very best; Gloriosum, a beautiful blush in early spring; Gibsoni, another favourite as a pot plant; Venus, of a fine blush when opening, changing to white, very fine; Jasminiflorum, which requires time to make a specimen, but will repay any amount of care

when in bloom; Dalhousie, one of the largest white kinds in cultivation, best kept from frost; Nivaticum, white spotted with yellow, very good; Glaucum, very dwarf in habit, of a pleasing light rose colour, the leaves having a white appearance on the under side, a fine sort for pot culture; Dauricum, nearly purple, a splendid plant when in bloom, but of rather bad habit, and requiring time, patience, and care to become a specimen, but which when such is once formed will repay any amount of care with its beautiful blooms in-doors in winter; Grand Arab, a most beautiful crimson, which ought to be in every collection; Iago, very dark and good, crimson purple; Black Blotch, one of the very best; Everestianum, pale blush, beautifully fringed, very fine; Fulgens, bright scarlet, having very compact trusses; Victoria, crimson purple, a beautiful variety; and Onslowianum, a pretty blush, fine yellow eye, very beautiful. I must not omit the Countess of Haddington, with beautiful blushes on her lovely cheeks, the flowers some 3 inches in length, and nearly as much in diameter, and the plant of first-rate habit. There are many more too numerous to mention, for all Rhododendrons make fine pot plants, and will repay any amount of care bestowed upon them.

The following are a few among this numerous race that I have noticed do well with ordinary cultivation in beds, or as single specimens, and are now in bloom. Fastuosum flore-pleno, an excellent sort; Coriaceum, a beautiful white; Everestianum; Mrs. John Waterer, one of the brightest-coloured varieties we have; Blatteum, fine, large, purple; Onslowianum, blush tinged with yellow; and Nivaticum, fine white with yellow spots. Dauricum will almost grow anywhere, and is the earliest of all out door Rhododendrons, sometimes flowering in midwinter and early in spring. It should be planted in a sheltered place, and have protection from frost and wet while in bloom, then it lasts in beauty a long time. Other kinds well worthy of cultivation are—Mrs. Loudon, very fine; Erectum, a fine trusser; Grand Arab, one of the most showy kinds we have; Mrs. Snowden, a good useful kind; Barclayanum, very beautiful; Sir Charles Napier, Nigricans, Sir Isaac Newton, Reedianum, Archimedes, Rosa elegans, Blandyanum, Arboreum, Maximum, Robustum, William Downing, Diadem, Gloriosum, Chancellor, Iago, and Cancasicum is a fine white of dwarf habit. Vandyke, though a late bloomer, is one of the finest Rhododendrons in cultivation. When the colours are nicely blended nothing can surpass a moderate collection of these beautiful plants at this season.—M. H., *Acklam Hall, Middlesbrough-on-Tees.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

Asparagus, except for some particular occasion *Asparagus* should not be cut after this time in private gardens. *Broccoli*, plant out once a fortnight to supply young heads in the autumn, and see that the seed beds do not become too much crowded. *Cabbage*, plant out a few young Cabbage plants about once a fortnight to keep up a supply of young heads in the autumn; also do not allow the seed beds to become crowded, as will soon be the case in moist weather. *Cauliflowers*, a few young plants from the spring-sown beds had better also be transplanted at short intervals rather than a large breadth at a time. If those now coming into use are likely to be more abundant than is required for the daily consumption, some of them should be checked to keep them back, if only by pushing in the spade on one side to cut half their roots. *Celery*, a short row of this may be put out and well watered to carry on the early succession, and the young plants for the main crops will require a regular supply of water if the rain do not find its way to their roots. *Succession crops* of Lettuces, Kidney Beans, Peas, &c., sow these according to the state of the last sowings, and see that the hoe is always in motion among crops in rows, whether there are weeds or not. There is one kind of work which is rarely thought of in summer—namely, trenching vacant pieces of ground as they fall in, but no method of improving heavy soil is equal to trenching it when perfectly dry in summer.

FRUIT GARDEN.

I suppose the Tomatoes planted out against the walls must be dignified with the notice of a fruit, if only to say that, like the ridged Cucumbers, they are often allowed to become too much crowded at the starting-off. The first high wind will then shake them about in all directions, two-thirds of their shoots must be cut off to make room for the rest, and this check throws them back ten days more; after such management,

people say in October the season was too cold to ripen the fruit, or give some other excuse equally groundless. Continue pinching, pruning, and nailing-in summer wood; and if insects make their appearance on any part of the walls or on bushes or standard trees, give them no rest till they are destroyed. Boiling water is the shortest way of dealing with ants when you find their nests. Remove all suckers from Filberts as they appear; examine the young fruit, and look after caterpillars, as they are making sad havoc in some places. Shorten and remove the summer wood of Currants and Gooseberries in the manner recommended for fruit trees lately. Allow the leading shoots to grow a fortnight or three weeks longer before stopping them; the result will be superior fruit, and finer-swelled and better-ripened buds for next season.

FLOWER GARDEN.

Where the beds in the flower garden were prepared for planting-out as directed some weeks ago, it will be necessary, after the ground is properly moistened, to hoe them over, distribute the soil from the sides over the surface of the beds, and then regulate the plants for the season. Make good all failures, and in pegging the plants down place them as much as possible with their heads pointing to the north, which will cause them to be drawn upright by the sun more effectually than if they were pegged out at random. As soon as the leaves of seedling Tulips become withered take up the bulbs. Great care must be observed not to injure them, as in most cases they push a bulb down several inches into the ground. Let them dry gradually in the shade. The beds of Ranunculuses should be frequently examined, as the green caterpillar, scarcely distinguishable from the stalk, often lodges just beneath them; they are also much infested with the cuckoo-spit (*Tettigonia epumaria*). Both are seriously detrimental to the bloom. Still persevere in the extermination of the green fly on Carnations, either by brushing off or by the use of Scotch snuff. Take off the laterals as they appear, and reduce the stems thrown up by strong-growing seedlings to one, so that the energy of the plant may be directed to the buds left. If you examine the buds of Pinks closely you may find some attacked by a small grey grub, which eats its way through the lower part of the calyx and devours the inside. An infusion of sheep manure will prove highly beneficial to the plants by being poured on the surface of the bed occasionally. Continue to propagate Pansies by slips or cuttings, and every seedling of inferior merit, or which is not a decided improvement on the varieties already in cultivation, may be pulled up.

GREENHOUSE AND CONSERVATORY.

Many of the greenhouse Polygalas might be so managed (with a little pruning about this time, and keeping them in-doors through the summer), as to come into flower early in January. Try also *Goodia latifolia* and some of the *Crotalaria*s in the same way. Perhaps there are some who are not aware that all the *Correas* treated after this fashion—that is, kept in the greenhouse in vigorous growth all the summer, will begin to flower late in the autumn, and continue to do so throughout the winter, supplying the place of the *Fuchsias*. The Mexican *Fuchsia splendens* is a late spring-flowerer, but if it is treated for the next three or four months as one would forcing *Heliotropes*—that is, cramped at the roots and allowed no more water than will just keep it alive, then giving a good shift and forcing it with the *Roses*, it will flower by the end of February. The planting-out in the open ground of *Fuchsias* to be taken up in the autumn to furnish the conservatory is an excellent practice which cannot be too much followed. This is about the right time to plant out such plants. *Leonotis leonurus* thus treated will produce double the quantity of flowers that it would under pot culture. The *Brugmansias* also do well in this way. *Luculia gratissima* delights in this treatment, but about the beginning of July will be time enough to plant it out. *Gardenia florida* and *radicans* improve very much under this treatment. Turn them out about the beginning of July in peat mixed with one-third leaf mould, and they need not be taken up until the approach of frost in October; then let them be put in a close frame for wintering, whence they are brought to the forcing pit in succession. Watering and training, with attention to shading, are the principal points to attend to now in the conservatory.

STOVE.

The *Hedychiums*, *Clerodendrons*, *Vincas*, and other stove plants mentioned last spring as useful auxiliaries for flowering in the conservatory in summer, should now be in good condition for flowering, and have large portions of air to inure them

to the change. The stove requires more air now, but still keep up a strong moist heat, and let the plants stand clear of each other.

COLD PITS.

Camellias, Chinese Azaleas, and the finer hybrid *Rhododendrons* that have been kept in heat since they flowered ought now to be turned into these pits for three weeks or a month before they are put out of doors; and as they will be nearer to the glass than they have been in the houses, they ought to be shaded slightly during hot sunshine. The best time of the whole year to graft them is when the bottom of this year's growth is hard and begins to turn brown, and the three families will take by grafting as freely as the Apple and Pear. Cold turf pits are just as useful in summer as they are in winter; and if they are only covered with the thinnest calico stretched on frames hundreds of plants will live and thrive in them better than anywhere else. Some of these should have a thin layer of soil to plant out young seedlings in, or newly rooted plants, and for young tender *Roses*, &c. All sorts of flower-garden plants may be propagated in them for the next three months, either in pots, or, which is better, planted out in a bed of light soil covered over with an inch of sand. Many other uses for them will occur in practice. Any labourer can put up such pits, and their size should correspond with that of the Melon pits in the same establishment, so that the frames may do for either.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Such heat after the rain was trying to some of our vegetables, and *Cauliflowers* heading nicely began to hang their leaves, so that we were forced to give a little water, as we had not time to shade. The soil on examination was found to be moist enough, but the little additional water just kept the leaves bold and unflagged; if they droop much even in bright sun, though all right in the morning, the heads are apt to come more open. To insure whiteness as well as compactness, it is well to turn some half-broken leaves over the flower, as the whiter the vegetable is sent to table the more delicate it looks. Except a piece of fresh-planted *Cauliflowers*, all other vegetables have been left to their fate.

Cabbages, &c., have swelled up wonderfully, so that our different plantings for succession threaten to come in too much at a time. Veitch's Matchless Cabbage still proves itself a fine variety for the amateur having little room. It can be grown to great perfection if planted one foot apart each way. Nevertheless, some of the larger kinds are useful when a large number of servants have to be supplied. In a nice plantation of Veitch's there are only three or four "rogues," and of the different sorts grown there has not been a single plant that has commenced running to seed. All the vacancies we owe to our visitors the rabbits. Some years ago we had many bolters. We hardly knew how the rabbits got out, but we found out how they got in. They went up outside a wall some 8 feet in height by means of some pea sticks and the bole of a tree, traversed the top of the wall for a distance of 40 feet, and then dropped down inside, a depth of more than 6 feet. Seeing the mark where they dropped, one or two were trapped; but their system was only stopped by placing wire netting across the top of the wall, past which they could not go.

Our other work was chiefly confined to routine, sowing Peas, *Cauliflowers*, Turnips, Radishes, &c., and giving water to Potatoes at the foot of walls, where they were becoming very dry, though almost fit for using. We may also mention that in forwarded and protected crops we have only met with two roots that had a trace of the dreaded disease. We have had nothing of that peculiar rotting of the stems below the surface alluded to last season.

FRUIT GARDEN.

Melons.—We are much obliged to Mr. Hall for his valuable remarks in page 387. We have long been so struck with the propriety of the cause he points out, that though we cannot always secure what we want, yet we would rather, if possible, not wet the foliage of *Melons* at all, if when under glass we could not have the leaves dry at least before the sun struck on them. In fact, if all be right, we hardly syringe *Melons* on this account, and we have had fine crops, which, besides watering the soil when necessary, never had any moisture on the foliage that could be avoided. Mr. Hall will perceive that we left air on at night, so that there was no confined vapour.

However generally applicable his remarks, and the having the foliage dry in the evening before much artificial heat is given we consider to be of first importance, still that will not explain the mystery how these two lights in the pit have been similarly affected for some years in the case of Melons, and nothing else, whilst the other three lights have generally escaped. If there be any difference in the artificial heat, that heat must be lowest in these two lights, as farthest removed from the boiler.

On a very sunny afternoon lately we noticed that the brick end of the pit inside was rather whiter than we like in summer, and we thought that the reflection of heat from the whitish surface in the afternoon might have something to do with this parching-up and scalding of the older leaves. A brush and some soot water soon darkened the wall sufficiently to make it an absorber rather than a reflector of sun heat, but in the two following mornings the large leaves in the plant nearest the end were as bad, if not worse, than before. We have trained strong vines from plants planted 5 or 6 feet from the end to fill the space, and these as yet are untouched in this way in their foliage. In this case the mystery is to us a mystery still, though we hope to benefit, and many more will be likely to do so, from Mr. Hall's very appropriate remarks as to dryness of the foliage, especially in early forcing.

The dung frames have thoroughly beaten the pit this season as to Melon-cutting, but, then, the pit was planted later, and, besides, the rats made such havoc with the young fruit. These rats found their way chiefly through the wall plate, and in addition to taking a ferret all through the beds every night, to leave at least some scent behind him, we shut him up in one of the worst haunts some nights. But as a hint to those with lots of young game near at hand, we may mention that the ferret scratched a way for himself up the wall, and made a hole through the somewhat-soft wall plate, and was only found after being at liberty a couple of days. There can be no question that the trail of the ferret gives a notice to the rat that he had better be out of the way.

After one of the hottest days last week, with the thermometer 85° in the shade, a blight seized some of our fruit trees, attended with honeydew, and lots of insects, especially on the Cherries. In this case the honeydew appeared before the fly, green or black. Some insist that the fly is the cause of the honeydew; we are inclined, on the other hand, to consider that the fly is a consequence rather than a cause, and that it comes to partake of the sweet food thrown out by a debilitated state of the tree. The observation of the circumstances at the time clearly showed that the trees were unable to meet the vast amount of evaporation demanded from their perspiring surfaces in such a high temperature, and that there was in consequence a thickening of the juices of the plant, and the more sugary part in a viscous state was forced through the foliage, which for a time would arrest the very free perspiration. This in cultivated trees would, if let alone, do this too much, and hence the syringe and the sponge are used in extreme cases to remove it. It appears less frequently under glass than in the open air, as under glass plants are not exposed to such sudden extremes. When the leaves are thoroughly varnished with honeydew they are as incapable of performing their functions as if covered with a coating of glue or isinglass. We did not do all that was necessary in the way of syringing, &c., but will have more time to lash those out of doors well before this meets the eye of the reader. Clean soap water one evening, followed by clean water the evening following, will generally make all right out of doors if persevered with.

In our orchard houses in these very hot days we prevented extreme heat by just sprinkling the outside glass with water coloured by whitening, and sprinkling with water the floor inside.

Vineries.—Thinned Grapes when cool in the second vinery, and have most of the plants out of the first. In the late vinery the weather has been everything for Vines in bloom and setting, and that with only a brisk fire heat in the few dull days when we had rain. The sun has been powerful enough to give a temperature from 75° to 85° during the day, and that, with damp paths and floors slightly sprinkled, gave a nice temperature for setting, with sun heat alone, and a moderate application of air, chiefly at the top of the house. Muscats have just had a dry hand pulled gently along their bunches—a practice which is a good one. This should be done when the sun shines brightly, and a few minutes will suffice to go over a great many bunches.

These late Vines have never seen the syringe or water on

the canes or foliage. Most likely, when all the bunches are set we shall give the house a good syringing to clear off more effectually all the remains of bloom, &c. The rods or stems generally break as well without damping or syringing as with it in the case of late Vines, and our water is generally such that we are afraid to use it much among Vine foliage. What rises as vapour from floors and pathways will be as clear and free from sediment as if distilled.

We notice on some of our Peach trees already a greyish-like appearance on the foliage, the result of sediment from frequent syringings with water, not so pure as we would wish it. For dread of the red spider we have been afraid to avoid syringing altogether in the case of the Peach, as we have long done in the case of the Vine; but when we have tried Peaches on a smaller scale under glass, and paid extra attention to syringing paths, floors, exposed walls, &c., before shutting-up, we did not find that the red spider was very troublesome, the foliage was bright green to the end of the season, and often in the morning the points and even edges of the leaves would be hanging with tiny dew drops.

Of course where water is clear and pure, free from earthy and chalky sediment, the syringe or garden engine is a great refresher and promoter of cleanliness; but when water holds such sediment, however clean it looks, it will leave the foliage anything but bright green at the end of the season, then it is well to know that we may do with less syringing if we do not soak our floors and borders, so as to paralyse root-action if the roots are there, but use about the same quantity of water in syringing the exposed surfaces as we would have done over the trees. In a hot day this may often be done at mid-day with advantage. The plants absorb the vapour as it rises, and distressing perspiration is for a time lessened, and such slight waterings on the ground or floor will never encrust a leaf with an earthy sediment.

We would not advise any reader to enter so fully into these remarks as to keep the syringe at rest as respects foliage, but we would certainly like if some of our enthusiastic amateurs would try a few trees in a small house with little or no syringing overhead, and report faithfully the result. Very trifling circumstances often lead to great changes in practice. But for such considerations as these referred to by Mr. Hall, and the knowledge that the Melon comes naturally to fine maturity with moisture enough below, but little moisture overhead, we might have gone on syringing Melon plants every night. But for water not free enough from sediment when frequently used, we might have syringed Vines overhead night and morning before they began to colour, as we used to do, though we are not aware that any bad result has attended the disuse of the sprinkling over the foliage, and it is seldom, indeed, that we have seen red spider on Vines even with no syringing.

From what little we know of the very varied climates of Persia, its excessive colds and burning heats, its hard clays and sterile sands, we should come to the conclusion that the finest Peaches and agricultural produce would be obtained from its northern parts, where in summer the climate is warm and moist. The latter produced more from exhalations from the marshes, and from the Caspian, than from the rainfall at that period of the year. Such gentlemen as Mr. Burton, of Hatfield, who could tell us from their practical observation, under what circumstances the Melon and Peach thrive best, and produced the richest fruit in such a country as Persia, of which the Peach is popularly supposed to be a native, might give us much help in the culture of such fruits here. True, under artificial circumstances, as under glass, we may, and, as in the case of the Pine Apple, do succeed all the better by not following too strictly the teachings of Nature; but still, the circumstances under which plants thrive best when grown in their natural habitats always furnish us with valuable ideas for regulating our practice, though it might be unsuitable to imitate these circumstances exactly. The idea we would wish to throw out for consideration is, whether in this comparatively dull and variable climate of ours, we do not in our houses have rather too much of the shower bath over the foliage, and whether that practice even when the water is pure, does not help to give size at the expense of flavour in the case of fruit, and spongy watery wood instead of smaller but firm shoots.

In addition to the Vines referred to, we may mention that perhaps the finest flavoured Melons we ever grew were thus treated. Strong plants in 7-inch pots were used, just beginning to run freely. They were turned out into rather stiff fresh soil—in fact a clayey loam, and made somewhat moist before planting, so that it was beaten pretty firmly together, and trodden firm

after planting. By means of small holes this stiff soil was well watered afterwards, and as soon as the surface was a little dry an inch of dry riddled mushroom dung was placed over it to prevent evaporation from the soil. In one case no more watering or syringing was given. In a second case, by means of upright drain tiles water was transferred to near the bottom of the soil, just as the Melons commenced swelling to ripening. Neither foliage nor the surface of the soil was wetted from the day of planting, but a few pans were set inside supplied with water. These experiments are best done in small places where the experimenter can attend to all himself. An assistant or a labourer may easily derange the whole. We merely mention it that people may see that the daily shower bath over the foliage is not absolutely necessary. These Melons had no great amount of artificial heat except in dull weather, and with a temperature averaging 60° at night, with air given early. So little was air given, that the thermometer often rose to 90°, and 5° more in the heat of the day when the sun was bright; but it rose gradually and fell gradually, and there was no confined scalding vapour.

ORNAMENTAL DEPARTMENT.

The hot days were trying to some fresh-planted subjects; but instead of deluging the ground with water and thus cooling the soil about the roots, and as shading such numbers of plants would be out of the question, the garden engine was employed twice or thrice during the day just to sprinkle the foliage, and what fell on the soil was soon raised about the plants by evaporation. One engine full of water would thus do a great deal of this refreshing work. One reason why our planting the flower garden takes so much time is the necessity of supporting most of the plants on account of the wind; and for this purpose we use rough bushy twigs, not very pretty at first, but which are soon concealed, and then they hold the plants quite firmly and securely through the season.—R. F.

COVENT GARDEN MARKET.—JUNE 3.

We have had a continuous steady supply, and business is rather more satisfactory than it was, but still falls far short of what we have been accustomed to at this season. Pines, Peaches, Nectarines, and Grapes are lower-priced than usual, and brought in much larger quantities. French produce is also amply supplied, and consists of Apricots, Cherries, Figs, Melons, and Strawberries, with the usual description of Salads, &c. Large arrivals of new Potatoes have reduced the price to 2½s. per cwt.

TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

CURRENT TREES WITH YELLOW LEAVES (C. C. E.).—The leaves are very beautiful, and if the trees would permanently produce such golden foliage

they would be an acquisition as ornamental shrubs. We think that the seven trees which produce them must be declining in vigour. If so, the addition of manure and mulching the surface over the roots would restore the natural green colour.

ACUCUA POLLEN (B. M. Royle).—The male blossoms have passed away a fortnight since.

DAPHNES (J. Lee).—You can obtain them from any nurseryman. There are many species, and they vary in price.

VINE CUTTINGS FOR NEW ZEALAND (T. Lord).—We think that they would arrive in a condition capable of vegetating if hermetically enclosed in gutta percha and sent by mail *via* Panama.

POLYANTHUSES (Auricula, Dublin).—Our correspondent, as well as many others, wishes to purchase a collection of these and other old-fashioned flowers. If florists who have them would advertise that fact, and state their readiness to send catalogues, we think they would find the announcement remunerative.

FLORAL COMMITTEE (A Subscriber, P.).—No fee is needed. Send your seedling Pelargonium on the Monday preceding the day of meeting, and write to the Assistant Secretary, Mr. Richards, at the same time.

SEEDLING PANSIES AND MINULES (C. S., Hillside Cottage).—The white seedling Pansy is a very fine flower, but not better than nor distinct from Queen of England and other whites. The hybrid Minulus between cupreus and another is a nicely formed flower, but too dull in colour. The seedling from Stuart's hybrid is bright and well marked. There are many seedlings like it.

CANDLE PLANT (An Inquirer).—If you send us a specimen we will endeavour to identify it.

NECTARINE LEAVES BLISTERED (Old Subscriber).—The leaves are blistered in consequence of cold nights succeeding hot sunny days. The circulation of the sap is obstructed, the whole or part of the leaves become inert crumpled masses, and are mostly attacked by white fungus or mildew. There is no remedy, but the evil may be prevented by affording a warm covering at night. It never shows itself on trees under glass. The blistered leaves should be picked off at once, and every encouragement afforded the tree to produce fresh healthy foliage.

GREEN FLY ON ROSES (E. A. S.).—I hand-kill and syringe. This is a sure cure. I have no faith in remedies. The leaves of my wall fruit trees (about 138 Peaches and Nectarines), are clean and beautiful. I never knew thrips and aphides so abundant. The peach aphid and the Aphid rose are not the same. Soft-soap contains arsenic; this and quassia, as you suggest, would injure nothing.—W. F. RADCLIFFE.

NERIUM CULTURE (Titmouse).—It is a good practice to place the pots in saucers kept full of water during the season of growth. They delight in moisture and a hot bright atmosphere.

POT ROSES MILDWEED (Idem).—Mildew usually shows itself on plants kept in a close moist atmosphere. The best remedy is to dust with flowers of sulphur the parts affected. A good preventive is to wash the walls of the house with lime and flowers of sulphur, in equal quantities, brought to the consistency of whitewash with a solution of soft-soap, 2 ozs. to the gallon. Also lightly coat the hot-water pipes with sulphur, brought to the consistency of putty with soapy water. Apply it with a brush.

PROPAGATING PERENNIALS (N. G.).—Saxifraga hypnoides is propagated by division of the plant after flowering, the divisions being taken off with a small portion of root to each. Plant them in light sandy soil, and keep moist and shaded until they become well rooted. Yellow Alyssum is increased by cuttings from now to September, the cuttings being taken from the growing point with a portion of the preceding year's stem to each. Insert them in sandy soil, afford shade, and keep them moist until well rooted. The white may also be propagated by cuttings and seed, and so may the yellow by seed. Now is a good time to sow it. The Double Lychnis may be propagated by cuttings of the young shoots from 4 to 6 inches long, taken with a small heel. Delphiniums are increased by division of the roots in spring. Each division should be taken off with a portion of root attached to it, and may be planted at once where it is to remain. They may also be raised from cuttings; the side shoots rising from the crown and not flowering may be slipped off, preserving a small heel to each, which should be pared smooth at the end, and inserted in sandy soil, giving shade from sun, and keeping them moist until rooted. Delphiniums are also raised from seed, which may be sown now. The herbaceous Veronicas are increased by division in spring, or now if they are not in flower, each shoot or division being taken off with a portion of root, inserted in sandy soil, and kept moist and shaded until growing freely. The shrubby Veronicas, as V. Andersoni, are propagated by cuttings, the young shoots being taken off with three joints, cut across below the lowest joint, and the leaves removed from the two lowest ones, putting in the cuttings round the sides of the pot and up to the leaves left. The pot should be well drained, and filled to within an inch of the rim with sandy soil, and then to the rim with silver or sharp sand. Place it in a frame, and keep close, moist, and shaded until the cuttings are rooted.

TAKING UP CROCUSES (Idem).—It is well not to take them up oftener than every three years, and then only for the purpose of dividing the roots, affording them more room, and enriching the ground, planting them again immediately. The operation is best performed as soon as the bedding plants are removed, or early in October.

FORGET-ME-NOT FOR SPRING BLOOMING (Idem).—The best blue Forget-me-not for spring blooming is *Myosotis montana*; but *M. palustris*, *M. arvensis*, and *M. alpestris* are most generally grown. The seed should be sown at once.

SOWING ANNUALS TO BLOOM IN OCTOBER (Idem).—Annuals to flower in October should be sown from the middle of June to the first week in July, and Gladioli to bloom at the same time ought to be planted in the second or third week in May.

PELARGONIUM GRAFTING (Idem).—You may graft your Giant Pelargonium with any of the Zonal kinds, but we do not think budding would be successful. Madame Kendatler, rosy salmon; Clipper, scarlet; and Rebecca, cherry, would be suitable kinds.

MAIDEN-HAIR FERN FRONDS DESTROYED (R. H. M. P.).—We think the fronds must be cut off by slugs, of which you may probably discover the traces, and if so, examine the plants after dark with a lantern. You will

and full instructions in the "Fern Manual," published at our office. It will suit you. You can have it free by post if you send sixty-four postage stamps to our office with your address.

MELON LEAVES SCORCHED (*Hortensis*).—There is no red spider on the leaf sent us, nor can we perceive any trace of the leaf having been infested with that insect. We think the leaf has been scorched by the sun's rays acting powerfully on it whilst wet, or from want of air during the early part of the day. The leaf is the thinnest and most rusted we ever saw. Give more air, and afford slight shade from bright sun.

WATERING PLANTS IN A GREENHOUSE (*F. K. A.*).—The best time for watering plants at this season in a greenhouse or elsewhere is in the evening, as the plants have the full benefit of the water for repairing the waste through evaporation during the day, and the moisture produced by watering is very beneficial to the plants at night, as they then inhale moisture.

RED SPIDER ON CUCUMBERS (*C. P.*).—We suppose your house is heated, and in that case we would have the pipes warmed to 160°, not more, and paint them whilst at that heat with a composition of sulphur, brought to the consistency of paint by a solution of soft soap, 4 ozs. to the gallon of water. The house should be shut up close and the pipes coated on every part with the sulphur composition, applying it with a brush. A few light sprinklings over the pipes it is well to give after they are coated with the sulphur composition, water being employed of the same temperature as that of the house, or rather of the pipes, so as to raise a good steam in the house, and thoroughly impregnate the atmosphere with sulphur fumes. This should be done in the evening, and a good watering given to the plants, and a thorough syringing in the morning. The back wall (if any) should be painted with the same composition as the flues or pipes. We would further advise your syringing with soft water, made by pouring thirty gallons over a peck of fresh soot, stirring it well, and syringing with the liquid when it becomes clear. The liquid well stirred up may be also used for watering the plants, and is an excellent manure for them.

STOPPING MELON PLANTS (*Idem*).—The shoot on which the fruit is produced, after being once stopped, should have the points of all succeeding growths taken out at the first joint above where last stopped. If the plants are weak the shoots may be allowed to make two or three leaves, then take out the points of the shoots. Without good foliage there cannot be fine fruit.

CUTTING OFF WOOD ABOVE GRAFT (*A. B.*).—The union of stock and graft being complete, and the graft growing freely, you may cut away the wood of the stock opposite the graft quite close to it now, but we prefer doing it the last week in June or beginning of June. It should be cut off slopingly, the knife being drawn towards the graft, and the face of the cut will then slope from, instead of as at present to the graft.

REPORTING PEACH TREES (*C. P.*).—You may report your Peach trees now if you do not value the fruit on them. Be sure they are well watered first, and the potting done finally.

PELAGONIUM SEED (*Sherbourne*).—*Pelargonium* seed sown in pans and covered lightly with fine soil will, on being placed in a hotbed of 65° to 80°, produce seedlings within a fortnight.

VERBENAS IN POOR DRY SOIL (*Idem*).—Mulch the bed or beds all over with an inch thickness of leaf mould or short manure mixed with an equal quantity of soil. Give the plants a good watering once or twice a week with guano water, 1 oz. being dissolved in a gallon of water.

WATERING PEACH AND NECTARINE TREES (*Idem*).—The trees may have a thorough watering with guano water, at the rate of 4 oz. to the gallon, once every week in dry weather, and fortnightly in moist weather, until the fruit commences ripening. A good syringing with water every evening in hot dry weather will be of great benefit, discontinuing it after the fruit commences ripening.

INSECTS (*C. M.*).—Your Peach and Apricot leaves have their under sides gnawed by the caterpillars of one of the case-bearing Moths, *Coleophora hemerobella*. We know no other remedy than hand-picking and burning the small moveable cases and their inhabitants. (*H. F. H.*).—We found no insects in the smashed box which contained your gnawed Laurel leaves. We suppose they have been attacked by the caterpillar of some Moth; but in the absence of more precise information we can only recommend careful examination of the trees.—*W. (Stockport)*.—It is one of the millipedes, *Julus pulchellus*. It is found on the roots of Beans, Cabbages, &c.

NAMES OF PLANTS (*P. Newton*).—*Passiflora (Tescosonia) manicata*. (*A Constant Reader*).—*Callistemon lanceolatus*. (*H. H. P.*).—1, *Veronica chamaedrys*; 2, *Cotoneaster microphylla*; 4, *Aspidodermis luteus*. (*W. S. H.*).—1, *Cydonia japonica*; 2, *Polygala myrtifolia grandiflora*; 3, *Mesembryanthemum formosum*; 4, *M. attenuatum*. (*A Constant Subscriber*).—1, *Leptospermum scoparium*; 2, *Fabiana imbricata*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending June 2nd.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

PACKING EGGS IN SAWDUST.

As there generally seems to be great disappointment in the hatching of eggs that have travelled, and some correspondence has arisen on the materials best suited for packing them, I send you the result from thirteen Black-breasted Red Game eggs I received from Mr. Wheeler, of Carlton, Notts. They travelled a distance of 140 miles, and yet produced eleven good strong chickens, and were packed in sawdust, which that gentleman tells me is the material he always uses, and which he considers has no superior. It certainly has the advantages of cheapness, cleanliness, and being readily procured.—*CONSTANT READER*.

BATH AND WEST OF ENGLAND SOCIETY'S POULTRY SHOW.

A most excellent Exhibition of both Poultry and Pigeons in connection with this Society, commenced on the 1st inst., at Falmouth. The long distance separating Falmouth from the midland and northern districts may have exercised an unfavourable influence as to the number of entries, yet in another way it told well, for though these districts contain many of our principal poultry yards, no doubt can exist that the expenses of carriage to so distant a locality weighed out in most of the classes the majority of indifferent specimens that so commonly help materially to make a show great in numbers rather than in good quality. We noticed, however, birds that were the recipients of first prizes from places so far distant as Hull and Sunderland.

It appears this season's month will be a very early one—in fact, not a few of even the prize birds betrayed symptoms of fast-approaching change of plumage. *Spanish* fowls were excellent, though as might reasonably be expected at this season, they were not shown in the

really faultless condition they might have been at an earlier date. *Dorkings* were in similar condition, and some few proved very gouty, though the majority were certainly good birds. In *Cochins-Chinas* the *Buffs* were the best shown. Partridge-coloured were next, and *White* ones were of fair-class quality. *Brahmas* were good, especially the *Dark* ones, though many had commenced their moulting. *Gans* were well shown as a whole, and the *Hamburghs* were especially good. *Polands*, except the *Golden*, were as good as could be wished for. The "Any other variety" class contained as good *Andalusians*, *White Spanish*, and *Black Hamburghs* as we have seen for some time past.

Ducks, Geese, and Turkeys were especially good, and the variety class for *Ducks* was of a very superior character indeed. The classes for single cocks were not heavily filled, but the birds sent were good.

The division of the Show for *Pigeons* was never so well filled at any former meeting of the Bath and West of England Society as on this occasion, and it remains a matter for consideration whether, in the "Variety class" especially, some additions to the prizes in future years might not with both justice to exhibitors and benefit to the receipts of the Society be allowed.

The very efficient services of the poultry Stewards, Dr. Brent and Mr. Bush, left undone nothing that was necessary for the perfect welfare and comfort of the birds exhibited, and as the weather was very propitious everything passed off most satisfactorily.

SPANISH.—First and Third, E. Jones, Clifton. Second, T. Bamfield, Clifton.

DORKINGS (Coloured).—First, R. Trevithick, Hayle, Cornwall. Second, Col. H. B. Lane, Lily Hill, Bracknell. Third, L. Patton, Taunton. Highly Commended, L. Patton; Col. H. B. Lane.

DORKINGS (White).—Second, Mrs. E. J. Hartwell, Bridgwater.

COCHIN-CHINA (Cinnamon and Buff).—First, W. A. Taylor, Manchester. Second, A. G. Crewe, Helston, Cornwall. Third, Col. Stuart Wortley, Grove End Road, London. Highly Commended, J. H. Dawes, Moseley Hall, Birmingham. Commended, J. Ralph, Perranarworthal, Cornwall; Hon. Mrs. Sugden, Wells.

COCHIN-CHINA (Brown and Partridge-feathered).—First and Third, J. Stephens, Walsall. Second, H. S. G. Stephenson, Lymington Rectory, Weston-super-Mare.

COCHIN-CHINA (White).—First, H. Loe, Appuldramhoe, Godshill. Second, J. H. Nicholls, Tanziar, Lostwithich. Third, F. Haworth, Haslingden, Lancashire. Highly Commended, H. Hobson, Walsall.

BRAMA POOTRA (Dark).—First, J. K. Fowler, Prebendal Farm, Ayles-

bury. Second, Col. H. B. Lane. Third, Col. Stuart Wortley. Commended, J. H. Reed, Calstock, Cornwall.

BRABMA FOOTRA (Light).—First, F. Crook, Forest Hill, Kent. Second, H. Dowsett, Pleshey, near Chelmsford. Third, E. H. James, Plymouth. Commended, J. Pares, Postford, Guildford.

GAME (Black-breasted and other Reds).—First, Rev. G. S. Cruwys, Cruwys Morchard, Tiverton. Second, A. Travers, Fulmouth. Third, S. Matthew, Chilton Farm, Stowmarket. Highly Commended, S. Dupe, Evercrech, Bath.

GAME (Duckings and other Greys and Blues).—First, S. Dupe. Second, S. Matthew.

GAME (Any other variety).—First, Rev. G. S. Cruwys. Second, S. Matthew. Third, Rev. F. Watson, Kelvedon, Essex. Commended, A. D. Edwards, Huddersfield.

HAMBURGS (Golden-pencilled).—First, S. R. Harris, Cusgarne, Gwennap, near St. Day, Cornwall. Second, F. Pittis, jun., Newport, Isle of Wight. Third, F. D. Mort, near Stafford. Commended, F. Pittis, jun.

HAMBURGS (Silver-pencilled).—First, C. Haworth, Haslingden. Second, P. Pascoe, Trevaies, Stithians, Cornwall. Third, N. Barter, Plymouth.

HAMBURGS (Golden-spangled).—First, Messrs. S. & R. Ashton, Mottram Cheshire. Second, J. Medway, Newton Abbott. Third, J. Strick, Devon Great Consols, Tavistock.

HAMBURGS (Silver-spangled).—First, J. Robinson, Farisworth, near Manchester. Second, N. Barter. Third, J. A. Taylor.

POLISH (Black, with White Crests).—First, Mrs. E. Procter, Hull. Second and Third, T. P. Edwards, Lyndhurst, Hants.

POLISH (Silver).—First, Mrs. E. Procter. Second, J. Hinton, Hinton, near Bath.

FRENCH (Any variety).—First, J. K. Fowler. Second and Third, Col. Stuart Wortley.

ANY OTHER DISTINCT VARIETY (Except French).—First, F. Pittis, jun. Second, Miss S. H. Northcote, Upton Pynes, Exeter, Devon. Third, R. H. Nicholas. Highly Commended, J. K. Fowler; J. Hinton. Commended, Col. Stuart Wortley.

DUCKS (White Aylesbury).—First and Second, J. K. Fowler.

DUCKS (Rouen).—First, E. Burton. Second, J. J. Stott, Quarry Hill, Rochdale. Highly Commended, H. Dowsett; L. Patton.

DUCKS (Any variety).—First, C. N. Baker, Chelsea (Mandarin Ducks). Second, Messrs. S. & R. Ashton (Carolina Ducks). Third, T. C. Harrison, Yorkshire (Pintails). Highly Commended, S. Dupe (East Indians). Commended, Mrs. A. C. Thynne (White Call Ducks); T. C. Harrison (Carolinians and Mandarins).

GESE.—First, S. H. Stott, Quarry Hill, Rochdale. Second, J. K. Fowler. Highly Commended, L. Patton. Commended, P. Knuckey, Treleaver, Mabe, Cornwall.

TURKEYS.—Prize, L. Patton (Cambridge).

BANTAMS (Gold or Silver-faced).—First and Second, Rev. G. S. Cruwys. BANTAMS (White or Black).—First, E. Cambridge, Stoke's Croft Road, Bristol (Black). Second, Messrs. S. & R. Ashton (Black). Highly Commended, Messrs. Tonkin & Tuckey, Bristol (Black); W. H. Tomlinson, Newark-on-Trent (Black). Commended, Rev. G. S. Cruwys.

GAME BANTAMS.—First, J. H. Robinson, Sunderland. Second, F. Pittis, jun. Highly Commended, E. Cambridge; T. J. Gilbert, Truro; E. Foder, Little Carlton, near Newark.

SINGLE COCKS.

SPANISH.—Prize, E. Jones.

DORRINGS.—First, Rev. E. Cadogan, Walton Pargonage, Warwick. Second, L. Patton.

COCHIN-CHINA.—First, Mrs. Christie, Glyndebourne, Glynde Station, Sussex. Second, J. K. Fowler. Highly Commended, H. Yardley, Market Hall, Birmingham; W. A. Taylor.

BRABMA FOOTRA.—First, J. Hinton. Second, Mrs. A. C. Thynne, Penstow, Stratton, Cornwall. Commended, H. Dowsett.

GAME.—First, S. Matthew, Chilton Farm, Stowmarket, Suffolk. Second, M. A. Forde, Castle Cary, Somerset.

ANY OTHER DISTINCT VARIETY.—First, Col. Stuart Wortley (French). Second, A. C. Thynne (La Fleche). Highly Commended, J. Hinton (Silver Poland).

PIGEONS.

CARRIEBS (Any Colour).—First, H. Yardley, Market Hall, Birmingham. Second, R. Fulton, Duke Street, Deptford. Highly Commended, G. S. Hockey, Durham Down, Bristol; C. Bulpin, Bridgwater, Somerset; R. Fulton.

TUMBLERS (Almond).—First and Second, R. Fulton. Highly Commended, J. Ralph, Perranarworthal, Cornwall.

TUMBLERS (Any variety).—First and Second, R. Fulton (Black Mottled and Agate Mottled). Very Highly Commended, J. Ralph (Red Mottles); C. Bulpin.

POUTERS.—First and Second, R. Fulton. Highly Commended, H. Yardley; C. Bulpin.

JACOBS.—First, R. Fulton. Second, C. Bulpin. Commended, S. Dupe, Evercrech, near Bath; C. Bulpin.

FANTAILS.—First, C. Bulpin. Second, H. Yardley. Highly Commended, Rev. W. S. Shaw, Beechen Cliff Villa, Bath; H. Yardley; C. Bulpin.

OWLS.—First, H. Yardley. Second, C. Bulpin. Highly Commended, F. T. Parker, Rosewarne, Camborne, Cornwall.

TRUMPETERS.—First, C. Bulpin. Second, Mrs. C. Gilbert, Truro.

BARRS.—First, R. Fulton. Second, C. Bulpin. Commended, H. Yardley; C. Bulpin.

TURBITS.—First, B. Wilson, Thirsk. Second, F. T. Parker. Highly Commended, T. Phillips, Hendra Farm, near Truro; H. Yardley. Commended, M. A. Forde, Castle Cary, Somerset.

NUNS.—First and Second, C. Bulpin. Highly Commended, H. Yardley. DRAGOONS.—First and Second, H. Yardley. Highly Commended, C. Bulpin.

ARCHANGELS.—First, H. Yardley. Second, C. Bulpin. Highly Commended, R. Wilson; H. Yardley.

ANY OTHER NEW OR DISTINCT VARIETY.—First and Second, H. Yardley. Very Highly Commended and Highly Commended, C. Bulpin. Commended, H. Yardley.

Edwd. Hewitt, Esq., of Eden Cottage, Sparkbrook, Birmingham, officiated as the Judge.

NOTES ON FANCY PIGEONS.—No. 11.

THE HORSEMAN AND DRAGON.

THE father of Pigeon-fanciers, at least the father of writers on fancy Pigeons—John Moore, A.D. 1735, was a man of education. Thus he latinised the names of each variety, and in his work there are marks of decided literary ability. One little touch we have in the Latin names which he gives to the Horseman and Dragoon. He calls the former "*Columba tabellaria minor*," the latter "*Columba tabellaria minima*," thus marking the differences with nice exactness. I would also mark the difference between the Horseman and Carrier. In the English army there are heavy dragoons and light dragoons, and this just applies to these two classes of birds. They are similar in shape, but differ in bulk, each part from beak to leg differing in size. It is clear that, once adopt the vulgar spelling "*dragon*,"—Moore spells the word "*dragoon*"—you lose the nice distinction indicated by Pope's "*learned friend of Abchurch Lane*." I suppose ignorant writers were more familiar with the "*George and Dragon*" public houses, and with the three jolly postboys said to be drinking there, than with the gentlemen in Her Majesty's cavalry service; hence their mistakes. Further, the two names are both connected with the idea of motion—the Horseman the heavy dragoon, the stronger but not so swift for short distances as the rapidly galloping light dragoon. Hence by what I have written in the article on the Carrier, that the Horseman is the original of that breed and not a mere degenerate Carrier, and by what I now say concerning the spelling of the word dragoon, and considering the antiquity of the breed, neither variety should be lost sight of, and their characteristics should be clearly given.

As the Carriers should be always black or dun, so the Horseman and Dragoon should never be of those colours. This would tend to keep up the distinction in each variety, and no one would be under any difficulty as to where the Carrier ended and where the Horseman began, or as to where the Horseman ended and the Dragoon began.

I would have prizes for Horsemen greatly dependant upon colour, its clearness, and soundness—thus, clear good Reds and sound Buifs, not washed-out colours; also Pieds, and Mottles as Trumpeters.

The Horseman, although interesting from its antiquity, is in itself scarcely so pleasing as the Dragoon, it being a type of strength minus grace, whereas the Dragoon is rather a type of grace minus strength. There are scarcely any of the minor varieties of fancy Pigeons more pleasing to the eye. First among colours are the Blues, in which the metallic hues on the neck are most beautiful. The fancier who can see without admiring a pair of first-class Blue Dragoons must be either very prejudiced or deficient in powers of appreciation. Next to Blues I rank Whites, which are singularly graceful, and when flying look like flakes of snow. The one fault of both Horsemen and Dragoons is their extreme pugnacity. I recently had one of the latter who would tyrannise without a minute's cessation over the other birds, following them from roof to roof, and tile to tile, his whole life being tyranny; and he, as all tyrants ought, was put to death after every attempt being made to cure him. Dragoons still maintain their supremacy on the wing, as I saw at two recent flying matches it was reported in each case, "*a Pigeon of the Dragoon tribe won*."

Of their rivals, the Antwerps, I must say a very few words. For exhibition they, as not being birds of colour or points, are useless. Their beauty is as nothing to that of the Dragoon. Wild, restless birds, of no manner of interest save as flyers—home, breed they seem to have none, and one pair produces birds of different colours. "*If birds of the Dragoon tribe*" beat them, what is their value? Nothing at all. And as the Antwerp is, so is the Skinnum. But on all account pursue steadily the breeding of the Horseman and Dragoon.—WILTSHIRE RECTOR.

P.S.—Still not a word by first-class Carrier breeders? Are there no writers of the class of Messrs. Huie, Ure, &c.? Surely there are. If there are not, Pouters may hold their heads higher than ever, and parade the earth in conscious supremacy.—W. R.

PIGEON-JUDGING.

ALLOW me to inform the committees of forthcoming Pigeon shows, that the principal requirement is too often neglected—viz., the selecting of the judge or judges.

It is a well-known fact that many good fanciers and exhibitors have of late given up the idea of sending their birds for competition, owing to their, in too many cases, having the mortification of seeing their birds beaten by others of third or fourth-rate merit. I consider that any man who takes the office of judge ought to state distinctly in the report of the show where he considers the first-prize bird beat the second and third. It would give the exhibitor who could not attend

the show some satisfaction to know where his birds were deficient, and it would also give exhibitors some proof of the judge or judges selected being capable of at least knowing first-rate from inferior birds.

If committees wish to have their pens well filled they will do well to have men selected to officiate as judges who have given proof of their sufficient knowledge. — ROBT. FULTON, *Shandon Cottage, Duke Street, Deptford.*

STRONG VERSUS WEAK SWARMS.

I HAVE all along advocated in these pages the superior advantages obtainable by keeping bees on the non-swarming or combination-of-swarms system, as compared with their subdivision into numerous single weak colonies by the swarming plan. The contrast is never more marked than during a poor honey season, such as the last, when swarms hived singly had too generally to be liberally fed to save them from a miserable death by starvation, while non-swarming or combined-swarm colonies, besides laying-up for themselves an ample store for winter's use, yielded in addition a fair though by no means average harvest to the bee-master.

To parties engaged in business away from their homes during the day, this system is peculiarly well adapted, as all that is required is a little attention during a morning or evening to see that the wants of the colonies are duly provided for by a gradual extension of the breeding and storing space, and in due time the bee-keeper is certain of reaping as rich a honey harvest as the district and season can be expected to yield. He is saved all risk of stocks dying from want, and trouble and expense of feeding, as such strong colonies usually lay up ample store, generally in excess of their requirements, and is spared, too, the mortification of finding on his return that swarms have escaped unobserved during his absence, and are nowhere to be found. It is a poor season indeed in which swarms combined do not yield honey enough to cover their value, while if established separately they often give nothing and require feeding. What a treat, too, awaits their owner, at least once a week, or on an odd holiday, to witness early in an afternoon such stocks in full work, the crowds that pour out and in, the air reverberating with their sweetest music, and such a brisk, happy, "all the more the merrier," look about every individual bee, bespeaking great internal prosperity, and a sort of infectious determination to "go at it," quite cheering to behold; while at an adjoining weak colony will be seen the odd dropper on the landing-board, possibly heavily pollen-laden, resting to draw its breath ere it struggles in out of sight, met by an outgoing forager who takes a leisurely survey whilst resting the wing, all telling too plainly that there will be difficulty here to make the two ends meet that is positively saddening to look at.

The great secret of successful bee-keeping is to possess strong combined colonies in suitable hives, offering ready facility for supering and nadiring as required, and so advanced

that these large bodies of reapers are all ready to turn to at the moment the main source of supply of the district is available, be it clover, lime, or heather. Under judicious management results may then be attained almost beyond the belief of the bee-keeper who weakens his stocks by indiscriminate swarming. Before such swarms hived separately can have their new domiciles furnished for full work, the staple is disappearing and the season lost. This combination system is of vital importance to us poor northerners, whose honey season is exceedingly short, and the weather so cold and variable to gather it in.

Swarms hived singly and weak colonies must each have their queen, comb-builders, nurses, and guards, as well as stronger ones; indeed, a much greater proportion must remain within-doors to keep up the required temperature, and, consequently, fewer foragers can be spared to go abroad, resulting too frequently, instead of a dividend to the bee-master at the season's end, in a most peremptory "call" in the shape of a liberal supply of sugar; whereas, the strong colony during the same season will yield a good return with a considerable addition to the "rest" account. If the small antiquated manufactory, with its manager and heads of departments, will not pay, while a handsome profit at the same time accrues to the proprietor of the large establishment with modern improvements—if it is found now-a-days, that the small vessel with its captain and officers in pay will leave a loss to the owner, at a rate of freight that to the proprietor of the full-sized ship gives a remunerating return—is it to be wondered at that the former are being rapidly displaced by the latter, and why should we bee-keepers be behind the "spirit of the age?"

It is solely to these principles being so well understood and practised, that the Ayrshire bee-keepers are enabled to send annually to the Glasgow market those fine octagon supers of clover honey, whose dazzling purity, straightness of work, and completeness of finish, are unapproachable anywhere, so far as I have seen, and a source of delight and puzzle to all bee-keeping tourists. Whatever they are in their own department of "flower honey," a correspondent of mine (Mr. Matthew Mitchell, Abington), ranks equally high in "heather honey," as he has shown this season by sending some of his beautiful workmanship to Glasgow. He has made the storing of the high-flavoured product of the heath, in glass, his especial study, and for his success in this direction stands unrivalled,

having for upwards of twenty years carried off the prizes at the Moffat Show against all comers, holding in addition five silver medals and one gold one for extraordinary specimens of his skill. Dissatisfied with all English and even French glasses which he could procure, he has of late years had such made of the purest crystal, after an original design of his own, which he found to answer the purpose admirably, and from the facility they afford of storing are now being generally employed in his own district.

These glasses, although uniform in pattern, are variable as to size, containing from 10 up to 70 and 80 lbs. I send you herewith a photograph of one, whose weight filled is 87 lbs., which is at present being exhibited for sale at his Glasgow agent's, Mr. James Clark, 99, Sauchiehall Street, and is attracting considerable attention, from its great size, beauty, and completeness of finish. It is better adapted for a bee-keeper's drawing-room ornament, or the centrepiece of some large honey-warehouse, than to be set on the breakfast-table of ordinary people. These glasses are complete in three portions, the body being removable from the pedestal or stalk to set upon the hive, the bees being admitted through a circular aperture at bottom 3 inches in diameter, and when filled the glass is replaced on the stand to set upon the table; the upper portion forming the lid, on raising which the honey can be removed as required. The vase-like form of the glass, the broader portion being uppermost, the reverse of ordinary glasses, has obvious great advantages for supporting massive combs.

Having already encroached too much on your valuable space, I must reserve till a future paper a description of the hive employed by Mr. Mitchell, and his mode of inducing bees to work in glass, which like the glasses themselves are quite original, and cannot conclude these remarks more appropriately as to the advantages of strong over weak colonies, than giving his own words in a letter before me, as to the colony which yielded the large glass above referred to. He says, "I put the first swarm in the box in the middle of July, added another in two weeks after, and in another week put a third swarm into it, then put on the large glass about the second week in August, and by the 10th September it was full as you saw it, and by the end of September the same. The colony yielded me altogether, in addition to the large glass, six smaller ones filled, and three others partly so, in all 169 lbs. of honey of the very best quality; the box when I took it weighed 75 lbs.—244 lbs. of a harvest altogether, so you will agree with me there is nothing like large quantities together. I had other swarms equally good, but as they remained single the best of them did not make over 20 lbs. of glass honey."

I had the pleasure of inspecting another beautiful glass of 83 lbs., together with several smaller ones, the whole being the produce of last season's work. When it is taken into consideration that Mr. Mitchell's apiary consisted of but twelve hives in all, and his situation is so very bleak, backward, and cold that his stock had to be fed nearly till the heather came into bloom, and that all the time he had to devote to his hobby was the short intervals he could be spared from his official duties—to his credit be it told, he has notwithstanding these many discouragements, with a numerous family to support on his weekly wages, struggled onwards to the attainment of such a high measure of success as to elicit the warmest sympathy and sincerest congratulations of all his apiarian brethren, as well as—A KENFREWISH BEE-KEEPER.

FEEDING CONFINED BEES.

In describing my friend's plan for preventing his Ligurians from crossing, I omitted to state that the nucleus box should be liberally fed during the period of incarceration.—M. J., Lockerbie.

[During our novitiate in bee-keeping, we once entirely destroyed a stock in a single night by feeding it, and keeping the bees confined to their hive at the same time.]

OUR LETTER BOX.

CHICKENS DYING (*Miss Jenner*).—We see nothing wrong in your treatment of the chickens. Give them bread soaked in ale once daily. Put the hen under a coop on grass during fine days, and on no account take the chickens from her. The eggs boiled hard are good for them, but give a little cooked meat on alternate days instead.

GAME COCK'S SPUR BROKEN (*North Devon Subscriber*).—The cock is not at all injured for exhibition. That only is injurious which might be done purposely to conceal a defect.

GOLDEN-SPANGLED HAMBOURG CHICKENS (*Constant Subscriber*).—Your feeding (mustard, bread and milk, and groats), is good, and the chickens can only die from some cause which is not mentioned in your letter. You might add some meal slaked with milk. Are your chickens fed the first thing in the morning, and frequently throughout the day? Have they dust in which to bask? Have they shelter from the mid-day sun if they require it? Are the coops out on grass? Is the hen quite confined in one? If any of these things are wanting, supply them. Put worm-wood in their water.

EGGS BROKEN IN THE HEN (*N. G.*).—Your Ducks are heated. All poultry die invariably from an egg breaking internally. It is impossible to extract it, and the broken shell lacerates the delicate membrane of the egg passage, causing death. Take a wing feather, and dipping it in oil lubricate the egg passage thoroughly. It is an easy and effectual remedy.

BUCKWHEAT FOR FOWLS (*Item*).—None of our English fowls do well on buckwheat, although it is the staple poultry food of France. We have tried it thoroughly without success. Tailing wheat is in our opinion extravagant food for adult fowls. It does for chickens as part food and part play, but it is not good for adults. It is not good enough. We know no food equal to ground oats, slaked with milk if possible. You must judge for yourself how much food they require. A good green Goose should weigh 6 lbs. Oatmeal is very good food for fattening ducklings; a little meat helps them.—B.

HOBAN CHICKENS (*E. H. P.*).—Your Hoban chickens should be hatched black and white. They should have five toes; six are too many, but they are not so objectionable as four. A Hoban with four toes cannot compete; it may with six. We will shortly give all the points of Hobans in detail. At present we can only say they should be square-bodied heavy fowls, have black and white-speckled five-toed legs, top-knot and beard. The cocks may have straw-coloured feathers, but positively no red; the latter disqualify. Neither legs nor plumage should be curiously black.

BANTAM CHICKENS (*C. X. H.*).—Bantams require to be longer with the hen than other chickens. Much depends on the time of year. Now, when there is scarcely any real night, and no cold or chill, the chickens are very independent of their mother. Still, as the brooding is beneficial, we leave them as long as she cares for them. Too often the hen is spiteful towards them at this time and in this weather. It would seem as though she knew her cubs were of less value than when the elements are contrary. If the hen will keep them they should not be taken away till they are ten or twelve weeks old. A Bantam hen should not be disqualified for any accident, but the loss of part of a toe is quite immaterial.

COCKS FIGHTING (*Peace*).—There is no possibility of preventing cocks fighting at times. We allow them to have it out, and the beaten bird has generally discretion enough to choose a walk of his own. When they are bent on fighting we generally tie a bag or an empty pillow case to the end of a long pole or rod, and as the birds spar before they attack, we buffet each of them, striking right and left. If this is continued for a short time they generally give it up. If not, there is little risk in allowing them to take their chance; they are never, or very seldom, killed.

SPANISH COCK NOT CROWING (*J. R.*).—Give him bread and ale, and of camphor pills one every day, the size of a pea. If we could be assured of their health, we often wish the cocks had lost their voices.

POULTRY IN CONFINEMENT (*Black Red*).—We quite approve your place and your food. Still we think you might have more change without incurring expense; chopped kitchen scraps, bread and milk, are not expensive. We think you might allow your chickens to run in the garden if you shut the hen in her rip. We have had the gravel paths of the kitchen garden studded with ribs, in which the hens were confined while the chickens ran about. Until the fruit begins we think they do far more good than harm in the kitchen garden, and the animalcule, of which they rid the place, agree with them marvellously. The plainest answer to your question will be to advise you to provide in confinement as nearly as possible all that fowls like and get when at liberty: dust for the bath, clean and cool water, soils of growing grass cut with plenty of fresh earth, and an occasional lettuce. If not to be borne in mind, fowls do not like their food cut up. They want all green food in such form that its weight will afford sufficient resistance to enable them to tear it in pieces.

BREEDING AGE OF ROVEN DUCKS (*Subscriber*).—Roven Ducks may be bred from till they are three or four years old. With Ducks of that age we prefer a young drake. The run will do perfectly well for Hamburgs, and they will be good egg-producers. Those fowls will thrive best that have the first half of the day for their liberty.

SHORT-FACED TUMBLER DISEASED (*Inquirer*).—We fear your bird is very old. The season, however, is in his favour. Let him have plenty of sunlight, bathing, and warming food, such as hempseed. Watch for insects. We greatly fear that in spite of all care and pains your bird will be useless, and, perhaps, after a short time will die.

PIGEONS UNSETTLED (*J. F. D. M.*).—We should think that your Pigeons are alarmed by hearing or seeing rats or cats, and are consequently unsettled. We judge from your drawing that the Pigeons for which you want a name are red-shouldered Turbids, or, if not, some of the many modern German Toys.

BULLFINCH COUGHING (*Marguerite*).—There may be a possibility of curing a bird of a cough and shortness of breath by putting a little saffron in the water, and removing the bird to a warm, but not too hot temperature. Birds will not do well kept in a room in which gas or a coke stove is used.

CANARY WITH LONG CLAWS (*Mary Peck*).—The nails of the bird should be cut with a pair of sharp scissors; but care must be taken not to cut too far as it would cause the toe to bleed. Too-deep cutting can be avoided by holding the bird up between you and the light whilst you are operating.

CAPPING A HIVE (*N. G.*).—A cap may be put on about three weeks after the swarm was given, and the bees are likely to take possession of it more readily if furnished with guide combs.

From observations taken near London during the last forty-one years, the average day temperature of the week is 72.1°; and its night temperature 47.9°. The greatest heat was 90°, on the 13th and 14th, 1842; and the lowest cold 30°, on the 11th, 1865; and 15th, 1850. The greatest fall of rain was 0.80 inch.

THE COMMON LAUREL AND ITS HARDINESS.

THAT the poetic associations attached to some plants have much to do with their popularity there can be no question, especially when the object selected is of itself worthy of all that is said in its favour. Thus it almost amounts to sedition to whisper anything against Roses, Forget-me-nots, Water Lilies, the wild Primrose, and others: all these plants possess merits of their own sufficient to establish a reputation apart from the ideal qualities often ascribed to them. Some other plants are less fortunate, their title to the honours attached to their names not being clearly made out. The national badge of the Sister Island, the Shamrock, is, notwithstanding all the inquiries that have been made about it, not by any means clearly identified; while a still greater doubt seems to exist whether the plant which forms the subject of the present article is at all entitled to the name it bears: the Laurel of olden times being supposed to be a different plant from the one now commonly called by that name, and I imagine it is vain to look for any authority to contradict or verify the correctness of the appellation.

As my purpose is to refer to cultural matters rather than to open a discussion on terms employed many centuries ago, I will not offer any opinion whether the Sweet Bay, the Laurustinus, Alaternus, or Phillyrea formed the type employed by the Greek sculptors, or whether it was the common Laurel of the present time which was represented by them. Certainly appearances are against the latter view, but it is enough that the present name has been adopted by all, and no one is ever mistaken when the term common Laurel is made use of. Nevertheless, a few years ago we were told that a superior variety of this species had found its way amongst us, to which the title of Colchian Laurel was given, and which, if really different from the former, rendered the name "common Laurel" more necessary than before. Now, as I have not had much experience with this new Laurel, and have some doubts whether the specimens I have met with are correct, I should like to hear the opinion of those who have grown this Laurel, and more especially how it deported itself in 1867 in places where the common Laurel suffered so much. An advantage which it was said to possess over the common Laurel was extreme hardiness: and as the latter plant certainly succumbed to the cold in many places, the greater merit is due to the Colchian Laurel if it passed through the frosty ordeal unscathed; but if not, its other merits, if superior to those of the common Laurel, ought to be told, or if it be merely the same plant slightly altered by circumstances likely to pass away soon, then let that be known also; in fact, anything bearing on the matter deserves to be made known, whether in favour of the Colchian or of the common Laurel.

I am the more anxious to hear of the hardiness and general character of this new Laurel (if it is a new one), from the fact of having witnessed so much damage done to

the old kind in so many places. Great were the lamentations at the losses sustained in this way, even in England, by the frost of January, 1867; in many instances large belts of this shrub 20 feet high were killed to the ground, or within a foot of it, and though most, if not all, of the subjects so killed down have grown again, the shoots in many cases show unmistakeably that the plants have been very much weakened.

My attention was called to the condition of the shrubberies at a place that previous to January, 1867, exhibited the highest possible luxuriance. The common Laurels with limbs almost approaching timber-size, had been so seriously hurt by the frost that the tops were all dead, and only a few of the stoutest stems showed signs of life for perhaps 4 or 5 feet up, and it was only a few of them, the tops from 6 inches from the surface being in most cases dead. Some had been cut down to the ground, some partly cut in, and others not cut at all, and in most cases fresh shoots were rising from the collar, but not so satisfactorily as could be desired. Doubtless the injury inflicted by the frost affected the after-growth, as it is reasonable to suppose that if the same plants had been cut down in a moderately mild winter the after-growth would have been much better than it was after cutting down the top that had been killed by the frost; but this is not the question that was asked at the time, which was this—Ought Laurels so injured to be cut down at once or not? My previous views were certainly in favour of letting them alone, and I am not exactly convinced that I was wrong; but there were some examples where a good result had followed cutting entirely down early in the spring. Now, who is right? In my own practice I let everything hurt by the frost remain untouched as long as possible when their appearance could be endured, and I have not seen any reason to regret it. The damage done here by frost even in 1867 was trifling compared to what it was in many places, so that I have not had the opportunities which others had of finding out the best way of recovering a frostbitten tree or shrub. My own opinion was certainly in favour of letting the plants alone as long as possible, while my friend the gardener was of a contrary opinion.

This subject in relation to Pinuses has, I believe, been discussed in the pages of this Journal, and in that case I certainly advised the scorched and fox-coloured foliage and branches to be let alone, and where this has been done much benefit has resulted. Whether the same treatment may be proper for Laurels and other evergreens not of a resinous nature is a question I should like to see taken up, as well as what is known with regard to the Colchian Laurel; for if additional hardiness could be imparted to so graceful and valuable a shrub as the Laurel, that result would be a boon to the ornamental planter, and especially to those living in parts of the country where the common kind is scarcely hardy enough to withstand ordinary winters, and make the desired progress.

As it is, the Laurel is more extensively planted than any other shrub, and for quickly producing an effective feature it cannot well be surpassed; but where it has been planted

to screen some unsightly object, and has answered the purpose for some years, it is very annoying to find some spring that the winter frost has killed it to the ground, and the object it was intended to hide is fully exposed to sight. If the Colechian Laurel will exempt us from such a misfortune it will be of no small value, and even those who in consequence of their favoured position may not require it, would be glad to make use of it, lest a more intense frost than that of January, 1867, should occur, or a repetition of it in places not affected at that time should make all sufferers.—J. ROBSON.

STRAWBERRY FLOWERS SCORCHED.

STRAWBERRY blossom has been unusually beautiful and abundant this season, giving promise of an enormous yield of that most estimable fruit. The weather has been all that could be desired for the setting of the flowers; warm, with bright sunshine; no sharp frosts as in the case of last year, when they destroyed nearly all the expanded blossoms, leaving us but a partial crop. This season we have suffered to the same extent from the opposite extreme—too much heat. On Tuesday, the 19th ult., the thermometer in the shade registered 87°, in the sun it actually rose to 147°; extremely high temperatures for this season, higher than are experienced during the whole course of some years.

I have been taking notes of the various forms, &c., of Strawberry flowers this season. On the evening of the 18th of May every bud, open flower, and fruit was perfect; next evening I found them scorched up and withered, as you will observe by the enclosed example. This is not a solitary instance, but is general all over the garden; every flower that was open, and very many of those in the bud, being destroyed. This result could have arisen from no other cause than the extreme heat of the sun, helped, no doubt, by the great dryness of the soil. The plants, I imagine, must have flagged considerably, although I did not observe them so affected, and suffered in consequence, as frequently happens with forced plants.

From the great abundance of blossoms on the plants, there will, I infer, be no actual loss of crop, as there were far too many flowers for the plants ever to bring to perfection; indeed, the flowers that are destroyed are just those that in forced pot plants are always cut off by good cultivators to allow of the better development of those remaining. Nature herself has here done what we seldom or ever think of doing with our open-air Strawberries, and that is to thin the blossoms when superabundant, so as to allow a better means of development for those that are left. It is from such lessons as these that we gain knowledge and experience.—A. B.

NEW ROSES.

I HAVE just flowered one of the new Roses, which I think promises to be a beauty. It is Mademoiselle Marie Larpin. It is of a pale flesh colour, deeper in the centre, somewhat of the colour of Caroline de Sansal, of exquisite shape, and good constitution. I shall watch its future flowering carefully. I have since bloomed La France, which fully justifies all my anticipations. It promises to be the premier Rose of the season; large in size, quite distinct, and with a most delicious perfume. How wonderfully early Roses are this year! and how wisely the Crystal Palace Company have acted in fixing their exhibition for June 20th! and how valuable a stock the Manetti is I have proved this year. I did not move mine until March, and yet they are now blooming very vigorously, whereas had they been on Briars they would have most likely perished.—D., Deal.

POTTING ORCHARD-HOUSE TREES.

In page 394 it is recommended that the collar of potted trees be kept high in order that water may not lodge there. Is not this contrary to the practice at Sawbridge-orth? There you see the top-dressing piled up round the pot, so as to leave a depression in the centre. I am perfectly aware that, as a general rule, trees should be planted high and dry, but potted trees in orchard houses are placed in exceptional circumstances. In the autumnal top-dressing the ball is left from year to year undisturbed, while round the edges of the pot new soil is placed. This new soil, until it becomes filled with new roots, is liable to turn sour if overwatered, while the central ball remains a hard dry mass. Again, the action of the sun upon the sides of the pot has a tendency to cause the

earth to shrink, and allow water to run off at the circumference. To counteract this last difficulty I have had many pots painted, first with linseed oil, and then with a coat of oil paint, so as to diminish evaporation; but the effect is only partial, and I still adhere to the plan of watering as near the centre of the pots as possible.—G. S.

[Quite the reverse of our recommendation. On the other hand, the potting-high of hair-rooted plants might never have been so general if the waterer had kept the water from dashing against the collar of the plant. Every man to his taste. You prefer a hole in the centre, we do not for reasons given. Even on your own premises—the earth shrinking from the circumference of the pot—we see a reason against your plan for pouring the water in the centre. We have no notion of a space between the ball and the pot.]

INSECTS.

(Continued from page 409.)

THRIPS, continued.—As there are plants which cannot safely be syringed with soft-soap solutions after fumigation, as I have recommended in page 408, a thorough syringing with pure water should be given to such twice or thrice a week for a fortnight or three weeks, after which all danger from the eggs will be past. Should the syringings, however, not keep the insect in check—indeed, should one appear, fumigate the house, and this repeatedly whenever a thrips is perceived; for when once established they are difficult to drive away, as though the original insects may be destroyed, they leave so many of their progeny behind that some time must elapse before they can be completely destroyed: hence the necessity for exerting great vigilance, and taking prompt measures to destroy the insect.

It may seem a wasteful proceeding to fumigate a house for the sake of one thrips. Without wishing to be considered extravagant, I submit that there is no economy in proceeding against such pests as this by half-measures. The means must be thorough, effectual, and the best mode of prevention is to treat a clean plant as if it were infested. There may be seasons when the attacks are not likely to be general; then the plant attacked may be treated singly, fumigated by covering it with canvas, or by placing it along with others in a small house, or if the plant will endure syringing with the soft-soap solution, that alone will be effectual, the plant being removed from the house for the purpose. A few thorough syringings will in most cases prove a good remedy in autumn and winter, though it is well even then to fumigate or dust the plants on the under sides of the leaves with tobacco powder, which is, perhaps, the best way of clearing individual plants, sprinkling them beforehand with water. The plants dusted should have a thorough syringing within twelve hours, and if delicate, as Ferns, the powder should be washed off again within six hours. The tobacco powder is also a good remedy for thrips on Melons, but is difficult to apply, as it is of no avail unless put on the under sides of the leaves, and that is difficult enough with plants in frames.

Melons are rather impatient of fumigation with tobacco. No harm, however, results to the leaves if the smoke be delivered cool, the foliage be dry, and a moist atmosphere be preserved during the following day, along with shade from bright sun. It is well to fumigate on two consecutive evenings, rather than to give one powerful dose that may destroy the crop. The same remarks apply to Ferns. They will not endure very powerful fumigation, hence care must be taken not to overdo it, and to have their fronds dry; but as they cannot subsist in a dry atmosphere every surface may be sprinkled with water prior to fumigation, so far as it can be done without wetting the fronds.

Avoid the use of soap solutions with Ferns, Melons, and similar-leaved plants; it is a certain means of rendering them black, and destroying them. Much may be done towards freeing plants of thrips by, in the case of Ferns, washing them with water by means of a sponge; and any large-leaved plants—that is, such as have smooth glossy leaves, may in the same manner be sponged with a soft-soap solution, at the rate of 2 ozs. to the gallon; but after some experience, I am convinced there will not be two opinions as to what is the best material, and the best means of applying it for the destruction of thrips—viz., tobacco smoke.

Plants in the open air are sometimes attacked with thrips. In that case make an infusion of 2 ozs. of tobacco in a quart of boiling water, and allow it to stand until cool, then strain, and add one gallon of the soft-soap solution (2 ozs. to the gallon).

With this syringe the plants, or dip them in it, and repeat the application if necessary, syringing the plants every evening in dry weather, and adopting other means calculated to insure healthy free growth.

Water as already stated being a natural enemy of thrips, the plants should be well syringed when making new growths, and afterwards, when these are mature, a good syringing occasionally will do good, and the temperature ought to be kept as low as is consistent with the health of the plants. It is the maintaining a dry, hot, close atmosphere that encourages thrips to take a hold on plants, and the way to escape its ravages is to give abundance of air, to keep the atmosphere cooler at night than by day, and to afford moisture plentifully.—G. ABBEY.

(To be continued.)

THE JUDGING AT THE ROYAL HORTICULTURAL SOCIETY'S SHOW.

THE Council of this Society does not seem to have made a very happy selection of Judges for the late Exhibition. One very glaring mistake was made in judging Variegated Zonal Pelargoniums; and I am sure one of the gentlemen selected to act as a Judge in this particular class is well qualified to fill such a position without fear or favour; but what was Mr. Grieve to do if he was opposed in his judgment by two others acting with him who were unfit, and incapable of distinguishing the difference between a Variegated Pelargonium and what is called a Variegated Zonal Pelargonium? The class to which I allude is intended for Variegated Zonals, and the schedule distinctly states, for "six Variegated Zonal Pelargoniums."

In the first place I would ask, Of what use is it for the Royal Horticultural or any other Society to print and distribute a schedule inviting exhibitors to attend the exhibitions, if the Judges appointed will not act according to the instructions set before them in the schedules?

In the class for Variegated Zonal Pelargoniums there were four collections exhibited, two of which ought most certainly to have been disqualified. A first prize was justly awarded to Messrs. F. & A. Smith, of Dulwich, whose plants were staged in a very neat way, were very even and compact, and, above all, every plant was a Variegated Zonal Pelargonium. Mr. Turner's collection ought to have been disqualified, instead of having an equal first prize with Messrs. Smith's, for this reason—one of the plants (May Queen), shown in his collection was not a Variegated Zonal. No trace of a zone can be seen in it. In Mr. W. Paul's collection there was also a kind named Snowdrop zoneless. This will show that only two collections were worthy of any award, and in justice to the other exhibitors the Council ought at once to publicly announce that it has rescinded the awards of the Judges, and that in the class for Variegated Zonal Pelargoniums only one first and one second prize will be given—namely, the first to Messrs. Smith, of Dulwich, and the second to Mr. J. Janes, the other two collections being disqualified.

The following is the order in which the plants were exhibited:—

Messrs. F. & A. Smith had Sunray, a fine Tricolor, in the way of Lady Cullum; Exquisite, a pretty Silver Tricolor, like Italia Unita; Miss Burdett Coutts, a handsome Silver Tricolor, and a decided improvement on Italia Unita; L'Empereur, a variety very much like Sophia Dumaresque; Metzer, very much like Mrs. Pollock, certainly little if any improvement on that variety; and Banshee, another Silver Tricolor, which appears to be a very finely improved form of Burning Bush. The above, were, however, well grown, the plants very even in size, and nicely got up.

Mr. C. Turner exhibited in his collection May Queen, a white-variegated Pelargonium, very much like Bijou, having no zone; Lady of Shallot, like the Countess, Silver Tricolor, having a faint pink zone; Princess of Wales, Silver Tricolor, very much like Italia Unita; Lady Cullum, one of our very best Tricolors, but the plant exhibited was a small one and looked quite lost by the side of Mrs. Turner, which is so much like it that it would puzzle almost the best judge in England to tell the two apart if the labels were removed; Mrs. Turner; and Sophia Dumaresque, also like Lady Cullum.

Mr. W. Paul exhibited two plants of his distinct and pretty Prince Silverwings, a mixed Silver and Gold Tricolor, and likely to make a very handsome bedding plant. The habit is very compact, and the style of growth neat and vigorous; Snowdrop, very much like Mountain of Light, a variety having

no zone; Plutarch, a fine Golden Zonal, having a fine, hold, and vigorous style of growth, with good flat leaves, very much like Florence; two plants of Louisa Smith. These, however, had very little colour, and did not appear to be any improvement on Mrs. Pollock.

Mr. J. Janes's collection, which should have been placed second, contained the finest and best-grown plant of Lady Cullum I have ever seen exhibited. It was a glorious mass of colour. Italia Unita was also a fine plant and beautifully grown, and if the other four had been better varieties, equal in size, and as well grown, they would have been the finest six Tricolors ever exhibited. I would advise Mr. Janes to procure four of the varieties shown in the preceding collection and present them in the fine style in which Lady Cullum and Italia Unita appeared in the dull and gloomy arcades (which are very little better than the dark arches of the Adelphi for exhibiting plants in), and I will undertake to say he will carry all before him. The other four shown in his collection were badly grown, and varieties possessing no merit. They were—Amy, no better than a badly-grown Mrs. Pollock; Beauty of Guestwick, Mrs. Benyon, and Little Pet, having a small and crumpled leaf. It is to be hoped that the Council will act more wisely in the selection of the Judges on the occasion of the Special Pelargonium Show which is shortly to take place.

In conclusion, I would suggest to the Floral Committee of the Royal Horticultural Society the propriety of affixing all their awards, properly describing the objects that have been awarded certificates, on the various plants before the public are admitted to see them. At the late Show I noticed a great array of certificates on plants on the third morning after the Exhibition was opened that were not on them the first nor the second day of the Show. To the names of the plants was simply added the inscription, "First-class certificate." This is a practice likely to mislead the public. It is highly important that the Society should publish a proper list of the awards given on the first day of the Exhibition. A Society like the Royal Horticultural of England should not show more favour to one exhibitor than to another. If this is not sufficiently intelligible to the Floral Committee, I shall be glad to have an opportunity of explaining my meaning more fully.—J. W.

PLANTS IN FLOWER IN MAY.

ACKLAM HALL, MIDDLESBROUGH-ON-TEES.

May 4,	<i>Prænia tenuifolia</i>	May 18,	<i>Sorbus aucuparia</i>

FRUITING OF THE ROSE APPLE.

THERE appears to be some error respecting the first individual who fruited the Rose Apple (*Eugenia jambos*), in this country. Neither Mr. Carr nor Mr. Mundell can claim the credit, and I cannot say with certainty who can. Mr. Vair had

the above-mentioned plant in fruit at Dangstein eight or nine years ago, and he says that Mr. Scott, of whom he received the cuttings, fruited it before that time in the gardens at Leigh Park, near Havant, Hants.—GEORGE NEWLYN.

STRAWBERRIES FROM PREVIOUS YEAR'S RUNNERS.

"FRUIT EATER" in his list of about forty kinds of Strawberries taken from the previous year's runners, and stating what proportion of them was then in bloom, omitted two kinds, which, from my experience, I should place amongst the best of our early Strawberries; I refer to Oscar and Eclipse.

I took three or four hundred runners of the above last autumn, merely removing them with a trowel from the bed where they had rooted, and ninety-nine out of every hundred have not only bloomed, but fruited, and most of them very heavily (some from forty to fifty berries, and very large), and I gathered a very nice dish of ripe fruit from Oscar on the 26th of May, and a dish from Eclipse the next day.

My soil is similar to that described by "FRUIT EATER."—J. D., *Sneyd Park*.

EARLY PEAS.—SUTTON'S RINGLEADER.

THE introduction of a new early Pea is not an event calculated to cause any great commotion in the gardening world, as very few seasons pass without one or more being brought forward, many of them being, as the Irish sergeant would have it, "an advance backwards," and some are only slight variations of old sorts. Indeed, so comparatively small has been the progress made during the last dozen years, that if the earliest sort previous to that date be sown side by side with the very earliest we now have there will not be much more than ten days between them.

These ten days earlier, however, are a great matter, and the only Pea which can perform that feat, with me at least, is Sutton's Ringleader, one which will, there is little doubt, become the parent of many better and still earlier varieties, and head a new chapter in Pea lore. From rows of it sown in the first week in February, I am now (June 1st), gathering well-filled pods, which is early for this cold humid part of the country, whilst a single row of Dillistone's Early and four of Sangster's No. 1 are only just beginning to fill the pods, although all were sown at the same time and on the same border. The last two sorts will, however, produce much heavier crops, and continue longer in bearing, as Ringleader, when grown on light soils, ceases flowering soon after the first pods begin to fill.

One circumstance in connection with this variety may be worth mentioning. As is well known, it is still somewhat high in price, resulting, no doubt, from the great demand for it during the last three seasons, so last year I managed to save about a pint of seed, which was sown along with those we are now gathering from, and the difference between the two lots is most marked, those from the home-saved seed being more than 6 inches taller, greener, and in every way more robust, and also four or five days later. This I am at a loss to account for, as it goes quite against all my other notions—they may, perhaps, be nothing more—about change of soil being beneficial to most crops. In the case of Potatoes, which for farm purposes we frequently exchange for others from a distance, and from different soils, it most undoubtedly is beneficial, and acting under the same impression I have procured Strawberry runners from a distance, instead of using those from plants which had been long grown in the same garden. Can the difference between the Peas be the result of wholesale crossing with some other sort in flower at the same time? or can the fact of the other seed having been grown in a sunnier, drier climate influence the habit in the succeeding year?—AVONSHIRE GARDENER.

NEGLECTED HARDY ORCHIDS.

I AM much pleased to see that some of your readers are at last paying attention to neglected border flowers. I should like to recommend to them the cultivation of the Hardy Orchids. As I grow about thirty species in the open borders, I can say from experience that there are few flowers more interesting, more ornamental, or more easy of cultivation. I have had this year *Cypripedium pubescens* with nearly fifty flowers on one plant, *C. calceolus* with nearly twenty flowers, and I have now in flower a good clump of *C. spectabile* with flower stems

nearly 2 feet high, and the flowers more than 3 inches across. These require peat soil, but I find that all the rest will grow almost anywhere. The common *Orchis mascula* is a handsome plant to dot about a spring border, and I know few flowers more ornamental than *O. maculata* well grown. The whole family does well in rockwork, where the roots are shaded, but the flowers can come up into full light and air. In such a place I find no difficulty in growing even the Marsh Orchids, such as *Epipactis palustris* and *Liparis Loeselii*. The only difficulty is in first establishing them, some of them being rather impatient of removal, but when once established and left undisturbed, they grow without any difficulty.—H. N. E., *Bitton Vicarage*.

VISITS TO GARDENS PUBLIC AND PRIVATE.

ARCHDEACON CROFT'S, SALTWOOD, NEAR HYTHE.

ON (so say the meteorologists), the hottest day in May that we have had since 1833, in company with some friends who were staying at the "Pavilion," Folkestone, I drove to see the grounds of the Venerable Archdeacon Croft, more especially The Alders, as they are locally called, although it might be better named the Rhododendron Valley. The drive was broiling, the dust was tremendous, but the treat at the end amply repaid all; and I came away with the feeling that the impression it made upon me some fifteen years ago—that it was one of the choicest pieces of landscape gardening I had ever seen—was in no way diminished by this sight of the place after so many years. It is just one of those places which it is impossible to describe, for words cannot, any more than drawing, set before us the varied beauties of such a spot; yet I would fain give some notion of it, so that if in another spring time any of the readers of the Journal should be in the neighbourhood, they may enjoy such a sight as they will not find in many places.

We sometimes hear of the Rhododendrons in such a place being so beautiful, but when we go there we find simply a mass of the commoner kinds which have obtained a congenial home and grown vigorously; but the case is entirely different with this beautiful spot. It was originally, thirty years ago or more, nothing more than a deep fissure, something like a railway cutting; and it has been transformed into its present beautiful condition by the taste and skill of Mr. Acomb, the gardener, and the liberality of the Archdeacon, the former enjoying the rare happiness of seeing the child which he had thus cradled growing up to its full perfection, the admired of all comers. This deep fissure has, then, been widened out; small pieces of water have been formed; and the most judicious and careful planting of Conifers, Rhododendrons, Azaleas, Kalmias, &c., has been made. Here you come upon a view, in the foreground of which is a fine plant of *Arancaria imbricata*, close to it a noble Rhododendron, and in the background some lovely plants of *Azalea indica alba*. On seeing these with their clear beautiful foliage and their profuse bloom, I could not but compare them with the tortured crinolines, and pyramids, and umbrellas that one has seen at exhibitions at home and abroad, and could only say, "*O! si sic omnia!*" And why should they not be? This over-training is a mistake; and I believe ninety-nine persons out of a hundred would prefer the more natural growth. But to return to the garden. These Azaleas have withstood 20° of frost before now; and this only shows how hardy they are, and causes one to wonder at the way in which they are tortured and coddled in private collections at times. Now we take another turn, and masses of the orange-coloured Ghent varieties and Rhododendrons meet the eye. Here, again, Ferns luxuriate in all their gracefulness, and now a huge tree of *Kalmia* unfolds its sunny blossoms; and so at every fresh step fresh beauties break in upon your view, and, if you be curious in such matters, new varieties unfold their blossoms for you. The Sikkim species flourish here, but as they bloom earlier than the other kinds, they were out of flower before my visit was paid.

Among the wonders of the place I may mention that *Camellias* grow here in the open air with only a slight thatching of the Brake Fern in winter. The size of some of the plants of Rhododendrons is very large, showing how thoroughly their treatment agrees with them. One in particular covers a very large space, and was much larger—I forget exactly the dimensions; but it was greatly injured by a severe snowstorm two winters ago, which broke the head out of it. The Archdeacon grudged no money to add to this beautiful collection; but I was struck by what his gardener said on this point—viz., that he used at one time to go up to London to visit the exhibitions

of Azaleas, &c., and was frequently tempted to buy some that he saw under canvas, but that when he obtained them and flowered them in the open air, there was very little if any improvement on the older kinds; and so, although you may find many of the newer varieties here, yet the older and better-known kinds are the most relied on. After all, it is not so much the individual plants as the judicious massing that makes the charm of this garden; and I venture to say that no one who takes my advice and visits this garden will be disappointed, but, on the contrary, will say that I have given a very poor idea of its unique beauty.—D., *Deal*.

OUR WILD PLANTS ON THE ROOF OF A LONDON RESIDENCE.

WHEN in the west end of London the other day I saw what I think you may be interested to know. I was staying at the house of a lady who is fond of Ferns, and who, in summers' outings in Scotland and Westmoreland, had collected some plants to form, if possible, an oasis in the desert of town life, and thought, and truly, that her success had been great. On the leads, without any shelter, or any care beyond that which ladies know so well how to give, I saw amongst many others two healthy plants of *Osmunda*, a fair *Allosorus crispus*, and, what astonished me more, a very fine plant of the Grass of Parnassus. You may judge how often such a sight has refreshed the owner, who, though an ardent lover of the country, is necessitated to live in town.—W. STOKES SHAW.

NOTES ON THE MANCHESTER HORTICULTURAL EXHIBITION.

THE demand for building sites has hemmed-in not only the London parks but similar places near other large towns, often much to the detriment of the trees, shrubs, and other plants there cultivated. So it has been with the Manchester Botanic Garden; for although it might at one time have been comparatively clear of the smoke and dirt inseparable from a large manufacturing city, the increase of trade is, of course, attended with a corresponding augmentation of all the evils which affect vegetation. Factories and dwelling houses rise up where smiling meadows and corn fields once refreshed the eye; long lines of streets and lofty manufactories vomit from their chimneys that black smoke which taints everything it comes in contact with. This state of things is by no means confined to the Manchester Botanic Garden, nor can it be well avoided, for to remove such a garden to what may be called a safe distance, would be to deprive so many of its use that the remedy would be as objectionable as the evil. Considering the evil, therefore, as one which could not be avoided, I was pleased to find on the late as well as on a former occasion when I visited this garden, that the plants under the care of the able Curator and his assistants were very well grown, although the trees and shrubs showed unmistakable tokens that all hopes of their attaining their proper proportions were out of the question. Soot, thick almost as the bark that encases them, formed an outer covering excluding all access of air, and giving that gloomy appearance to the whole which the spectator from a more healthy district sees more readily than those who are accustomed to a smoky atmosphere. To contend against this is extremely difficult, and can only be done successfully in the case of subjects whose existence is short, or which are immediately under the care and control of the cultivator—in other words, only plants cultivated under glass, or which occupy the flower beds during the summer. No doubt these would do better if they were in a more healthy neighbourhood; but as it is, those in the Manchester Botanic Garden are creditable, and many of those under glass are well-grown specimens, showing that much care and skill had been exercised in their management.

The Botanic Garden of the great metropolis of the cotton trade occupies a nearly level position on the south side of the town. The country, it may be remarked, is level for several miles round, not so dead a level as those alluvial lands known as fens or marshes in other parts of the kingdom, but destitute of any great elevation. The soil is of a black, sandy nature, evidently well adapted for the *Rhododendron* and *Potato* were the atmosphere more pure; and many other plants would thrive well in the garden were it not for its proximity to chimneys. The entrance is a fitting one, with

suitable offices adjoining it; and, partially concealed by trees, to the left is the range of houses for plants, while to the right is the large conservatory which, like that at Kensington, is more used as a receptacle for plants exhibited at the various shows than for those grown in it. Indeed, the building, I believe, was designed solely to hold the horticultural shows in; but shows, like other things, outgrow their original dimensions, and additional space was, in the case of the recent exhibition, obtained by uniting the exhibition building to a large tent, or rather a series of tents. In one of the principal of these the ground is thrown up into a series of terraces and turfed over so as to form stages for the plants, instead of the latter being placed on the too-common wooden tables covered with green baize. Other tents adjoining were devoted to cut flowers and some special purposes, but the bulk of the flowering plants (*Pelargoniums*, *Calceolarias*, and *Fuchsias* excepted), were in the exhibition building and the tent with the turf banks. A sort of elevated platform where the two united gave the visitor a good view of both.

I now come to the subjects of exhibition, and in the first place may say that most of the stove plants, *Orchids*, and other tender plants were placed in the permanent building, and the more hardy ones under canvas. The arrangement of the former was necessarily confined by the nature of the building, and as a whole did not look so well as the latter, many of the plants being at so great a distance from the observer. The house was divided longitudinally, and the plants staged against the two sides, with a large space for a path in the centre. Most likely it would be difficult to arrange the plants otherwise; but if it could have been done so as to have placed some of the plants that were 12 or 15 feet from the spectator somewhat nearer, it would have been better. As it was, those at the back were only imperfectly seen, and the groups were not so well defined as at some other exhibitions; nevertheless, the general effect was good.

Many of the plants were very large, and those from the garden of H. Micholls, Esq., of Bowden, and from Messrs. Cole, nurserymen, Manchester, were excellent specimens of cultivation. Not less so were those of other cultivators, who showed them in smaller numbers. An important prize for a group of plants deserves to be more generally adopted by the managers of exhibitions; it was one for ten plants in flower and ten fine-foliaged plants. The combining of the two in one group had a good effect, and deserves to be repeated at most shows of a like kind; only where such combinations are made it is certainly advisable to exclude the mathematically trained *Azaleas* and other plants, which present too rigid and formal an outline to keep company with those having graceful and flowing foliage. There can be no objection to *Azaleas* and similar plants forming part of the group, but it is certainly bad taste to introduce those which are stiffly trained; and if the latter had showed less conspicuously that they were indebted to wires, sticks, and strings for the form they appeared in I would have liked them much better—in fact, I am not sure but that the whole would have been better without being trained at all if they could have been brought to the Show, but this is more difficult to do than with a stiff-trained plant. In the mixed group stiff training ought to be excluded.

Pelargoniums of the Show and Fancy varieties were less numerous and hardly so well managed as I have seen them at some of the London shows; but the *Calceolarias* were good, and there were several groups or collections of the now popular *Tricolor Pelargoniums*, including most of the varieties already known to the gardening world, and several new ones. A large collection of seedlings from some one whose name I failed to find out, promised to be very fine. Other novelties there were, amongst which I noticed a collection of *Coleuses* from Messrs. Veitch, which I was told were those recently purchased from the Royal Horticultural Society. Of the merit of these it may yet be premature to give an opinion; but unless the after-foliage improve in appearance there seems really little to admire in them.

Cut flowers were but sparingly exhibited, and I missed the baskets of cut flowers which I have seen elsewhere. Hand bouquets of the usual type were numerous, and the prize wreaths for the head were the prettiest I have seen. The bridal bouquet was also well arranged. Maiden-hair Fern formed a portion of almost all the bouquets exhibited.

A tent devoted to the Tulip was very sparingly occupied, and the merits of those exhibited might have been better understood some forty or fifty years ago than now. As it was, the general public paid them little attention.

Fruit was good, but less in quantity than might have been expected in a locality where it is so well grown as in Lancashire, besides which, the liberal prizes offered might have tempted exhibitors from a distance as well. The prize Pine was from Hertfordshire, and it well deserved the distinction it received. A Queen of 6lbs. in May is not a fruit often to be met with; but it may be as well to remark here, that the Pine chiefly grown in this part of England is the Jamaica, just as the Cayenne is in Scotland, and the Queen around London. Black Grapes were good, but the white ones were, perhaps, hardly ripe, and the collection of four kinds was far from being good. Strawberries were not remarkable, it being too early for the out-door fruit, and perhaps those grown under glass were becoming scarce.

Of other subjects exhibited, there were numerous examples of boilers, one or more with a quantity of piping being at work. Some of the boilers were not intended to be encased in brick-work, but to stand open. Economy in fuel was also one of the features aimed at. The friends of the tubular boiler are certainly fewer than they were some years ago, but I expect further improvement in the saddle boiler, some of those exhibited being of a sort intermediate between that and the conical. Amongst the boilers exhibited some were very useful, and it is certainly important that such should be made known at exhibitions. Although not connected with horticultural heating, I noticed some ingeniously-contrived chimney tops to cure smoky chimneys. One with a revolving top was so contrived that its spindle turned a sort of winged screw, not unlike in construction the wings of the screw propeller of a steamboat; to appearance this must pump up, as it were, the air in the chimney, and so long as it keeps in motion one might expect exemption from smoke. There were also some modifications of this screw, some of the wings being nearly of a cup form. I was not surprised at the attention paid to this contrivance, evidently by those who were sufferers from smoky chimneys.

Garden seats were exhibited in great variety, also mowing machines of all sizes, syringes, tools, and implements of all kinds; but one of the most common of all was here, as it generally is on all similar occasions, conspicuous by its absence; for, notwithstanding the improvements every article has been subjected to, we never see nor hear of a wheelbarrow at such exhibitions, and nothing in everyday use is more in need of improvement. A neat handy barrow for garden use is one of the rarities one meets with only once or twice in a lifetime, and I am not sure that I have ever done so yet.

The arrangement of the whole Exhibition was admirable, and I hope was duly appreciated by the manufacturing public, of which Manchester is the centre; for the Show was to continue open about a week, the latter days at such a price as to admit the million on the most important holiday week they have in the year—namely, Whitsun week.

A notice of this kind would not be complete without mentioning that the flower beds in the panel garden immediately in front of the Exhibition house were all planted with their summer occupants, consisting of Pelargoniums, Lobelias, Calceolarias, and similar plants; while in a reserve ground behind I noticed a quantity of plants that had evidently been removed thither only a few days, being the "spring gardening" bulbs and plants. The system of having two crops of flowers on the same ground is trying alike to the energy of the cultivator and the qualities of the soil. The latter I expect will be enriched by manure, either liquid or solid, and there is no doubt as the summer advances the display will be good, as the plants were certainly planted thickly enough. Of course a favourable season or otherwise influences everything; but in the moist climate of Lancashire one of the elements of success—rain, will probably not be wanting, as it has been in some districts. All parts of the ground were in good keeping, and the walks being mostly composed of gas tar and crushed Derbyshire spar, or a hard white stone resembling that substance, looked well, and many of the public walks in the district were made in this way, with now and then a dash of crushed brick as well. The mottled appearance such walks present contrasts strongly with the dull brown gravel used elsewhere, and I need hardly add that such walks are always clean. A visit to the great metropolis of the cotton district will reveal much that is useful in this way; but if the traveller be from a favoured rural district in one of the southern counties, he will feel reconciled to its not having the advantages which a manufacturing district possesses, on observing how dwarf, dingy, and unhealthy every shrub or tree appears; while the care, skill, and energy dis-

played in the culture of plants under glass, and the success achieved with them, will convince him that all the skill and dexterity of the dwellers in these districts are not absorbed in mechanical pursuits, for those following the more ancient calling of the gardener are as a body second to none of their brethren in other parts of the kingdom.—J. ROESON.

FERTILISING SHY-SETTING GRAPES.

MUCH has been written upon the setting of Muscat and other shy-setting Grapes; and in THE JOURNAL OF HORTICULTURE of January 30th I read the following paragraph written by Mr. Budd, gardener, Cobham Hall:—"To set the Muscat of Alexandria like the Black Hamburg, keep the day temperature at 75° by fire heat, and 85° with sun heat. Keep the night temperature at 70°. Damp the paths at 7.30 A.M. and at 4 P.M. Keep the whole of the atmosphere of the house in perpetual motion night and day. When the blossoms are fully expanded give each bunch a slight shake once a-day. This is all that is necessary to ensure well-formed bunches."

My experience from having set and fruited our new Grape, Mrs. Pince's Black Muscat, on many occasions in pots, with smaller canes growing for sale, where the atmosphere must as a rule be kept very moist, led me to believe in and adopt Mr. Budd's plan to the very letter. The whole of the vines here have set better this year than I ever saw them. The small house in which Mrs. Pince's Black Muscat is growing is truly a sight worth seeing. The bunches really touch each other; and as I shall have to take off more than half, I send you a part of a bunch, that you may see that every berry has set. I shall be glad to know if others have tried Mr. Budd's plan.—SAMUEL RANDALL, Manager to Lucombe, Pince, & Co., Exeter.

[Nearly every berry was set in the portion of the bunch sent.—EDS.]

CROSS-BREEDING THE POLYANTHUS.

New varieties of the Polyanthus, indeed of all florists' flowers, are raised from seed, and in fertilising them the experimentalist may vary his operations according to his taste, judgment, or requirements. If size be wanted, take Buck's George IV. for the seed-bearing parent, if refinement, Saunderson's Cheshire Favourite, and impregnate them with the pollen from a flower containing such properties in colour or marking as you wish to impart. The *modus operandi* is as follows: Take a strong truss of the variety selected for the purpose; remove the small pips, leaving five or six to be operated upon; take out the anthers with a pair of small forceps or tweezers as each pip opens; when fully expanded collect the pollen from the best pips of the variety selected for that purpose, with a camel-hair pencil that will not scatter it; introduce it into the tube, and forcibly turn it round upon the stamps of the removed anthers; repeat this process several times; cover the truss with the piece of glass mentioned before [see page 375], to keep wet or insects from injuring the fertilised pips, and Nature will work her own way.

When the seed-pods are turned brown, and just about to open, gather them; store them in a dry place until you sow them: the best time for this is probably in February. Fill some boxes, pans, or shallow pots to within 1 inch of the top with rich garden mould, then sift or rub half an inch of very fine soil, and sow the seed; only just cover it with fine-sifted soil, water with a small rose pot, and take care never to let the seeds get dry after they begin to germinate. When the seedlings are large enough to handle, transplant them in a shady border, free from drip, about 3 inches apart; attend to watering and top-dressing, and in due time this labour will be rewarded by the appearance of some "gems of purest ray serene."

I will just mention a method I have adopted as a temporary shade, and I find it well adapted for a sunshade during the summer months. On the back of the short stake in which I fix the piece of glass for protection to the bloom, I hang with a single tack a piece of perforated zinc, about 5 inches by 7; this admits a free circulation of air, and prevents the rays of the sun striking directly upon the plants.—DERA (in *The Gardener*).

CRYSTAL PALACE ROSE SHOW BREAKFAST.—The refreshment contractors promise to provide breakfast at 10 A.M. if they are informed how many are likely to require it at that time. Last

year we could get nothing like a breakfast until twelve o'clock. Will such exhibitors as intend to avail themselves of the contractors' offer kindly drop me a line by the 16th instant? and I will communicate the probable number to the contractors.—
R. B. POSTANS, Brentwood, Essex.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

CYMBIDIUM PENDULUM, var. *ATRO-PURPUREA* (Purple-flowered pendulous Cymbidium).—*Nat. ord.*, Orchidaceæ. *Lin.*, Gynandria Monandria. Native of Java. Flowers purple, green-tipped; lips white, rose-tinged, and purple-blotched. — (*Bot. Mag.*, t. 5710.)

ERANTHEMUM ASPERSUM (Speckled-flowered Eranthemum).—*Nat. ord.*, Acanthaceæ. *Lin.*, Diandria Monogynia. Stove shrub, introduced from Solomon Islands by Messrs. Veitch. Flowers white, blotched and sprinkled with dots of purple. — (*Ibid.*, t. 5711.)

OPHRYS INSECTIFERA, var. *ARANIFERA* (Spider Ophrys).—*Nat. ord.*, Orchidaceæ. *Lin.*, Gynandria Monandria. Native of England, but specimen here portraited came from Mentone. — (*Ibid.*, t. 5712.)

STROPHANTHUS CAPENSIS (South African Strophanthus).—*Nat. ord.*, Apocynaceæ. *Lin.*, Pentandria Monogynia. Conservatory evergreen climber. Native of the Kaga-berg forest, near the Cape of Good Hope, at an elevation of 5000 feet. Flowers yellow and orange. — (*Ibid.*, t. 5713.)

ERYTHRONIUM GIGANTEUM (Gigantic Erythronium).—*Nat. ord.*, Liliaceæ. *Lin.*, Hexandria Monogynia. Native of North-west America. Flowers white; claw green behind, yellow in front. — (*Ibid.*, t. 5714.)

STOBÆA SPILROCEPHALA (Round-headed Stobæa).—*Nat. ord.*, Compositæ. *Lin.*, Syngenesia superflua. Native of South Africa. Heads golden yellow. — (*Ibid.*, t. 5715.)

HYBRID PERPETUAL ROSE, Duke of Edinburgh.—Raised by Messrs. Paul & Son, Cheshunt. Deep scarlet crimson, petals large and stout. — (*Floral Mag.*, pl. 389.)

EPIDENDRUM INAGUENSE.—Introduced by Messrs. Backhouse and Sons, York, from the elevated regions of the Mexican Cordilleras, where the temperature in winter falls to 40°, so that this Orchid would endure cool treatment. Flowers scarlet orange. — (*Ibid.*, pl. 390.)

CAMELLIA, Madame Ambroise Verschaffelt.—Raised by M. Verschaffelt, of Ghent. Pale blush, with pink flakes. — (*Ibid.*, pl. 391.)

TRICOLOR PELARGONIUM, Star of India.—Raised by Messrs. Rollisson. Flowers bright scarlet; leaves green-centred, with a band of crimson, and a yellow edge. — (*Ibid.*, pl. 392.)

LILIUM THUNBERGIANUM PARDINUM (Leopard-like Thunbergian Lily).—"The bulb of this beautiful Lily was purchased by G. F. Wilson, Esq., of Gishurst Cottage, Weybridge, at a sale of Japanese bulbs, and formed part of a mixed lot, comprising *L. tigrinum* and *L. auratum*. It is very distinct from all the Japanese Lilies known in England, and appears to be nearly related to *L. Thunbergianum*, though it differs somewhat from that species in its narrower leaves, and in the warty instead of glabrous surface of the base of the petals. The colours are also distinct, the centre of the petals being stained with golden yellow, and the whole surface being dotted over, as in the Tiger Lily, with dark spots. It is one of the most beautiful hardy Lilies we have seen. It has the general habit and aspect of *L. bulbiferum*, but differs in the flowers being quite smooth on the outer surface, and in the colour and markings. We suspect it may be a hybrid, in which case it might bear the name of *L. pardinum*.

"We learn from Mr. Wilson that the plant grows about a yard in height. It has a stoutish stem, which is furnished with smooth lanceolate acute leaves, these being nearly an inch broad and 4 inches long, with about three principal ribs on each side the central one, and several smaller ones lying between them. The flowers are each about 5 inches across when expanded, and are arranged in a terminal umbel, containing several flowers, the pedicels of which are branched so as to give three successions of buds, and furnished at each ramification with an ovate acuminate bract. The segments of the perianth are so far narrowed towards the base as to leave distinct openings at the base of the flower; they spread out into a shallow vase-like form, with the apices incurved; the sepaline ones are about 1½ inch broad and nearly 4 inches long, the petaline fully 2 inches broad, and the stamens about 3 inches long. Each

segment has two raised ridges running throughout its length, forming between them a deep sharp furrow, the lower portion of which is closed and distinctly bearded with short hyaline interwoven hairs. Several other indistinct ridges appear near the base of the segments, but these break up more or less into prominent warts, some of which are tipped by a black spot, and others by a stellate tuft of hairs. The filaments and style are orange red.

"The ground colour of the flower is of a reddish orange colour, the central portion of each segment being of a golden yellow, and the whole surface nearly to the edge marked over with dark-coloured dots similar to those of the Tiger Lily. The flower indeed may be described as having the general form and character of *L. bulbiferum*, the colour and spotting of *tigrinum*, and the golden band of *auratum*."—(*Florist and Pomologist*, 3 s. i. 121.)

VIOLA CORNUTA ALBA.

ANOTHER valuable addition has this season been made to the collection of desirable hardy bedding plants, and fine combinations of colour may now be produced with the Violas alone. This latest addition will prove most valuable for edgings, as there are so few white-flowered plants suitable for the purpose. Many of the white-foliaged plants used, such as the *Cerastium*, the *Centaureas*, &c., are too formal, except in geometrical arrangements; but for all beds surrounded by grass I consider the plants employed to form edgings should be neat and graceful, I therefore anticipate that *Viola cornuta alba* will become an especial favourite for this purpose. Its foliage is neat, and its habit very compact; it may be planted with the other two gems, *Viola cornuta* and *Viola lutea*, and would produce a charming effect around a bed of *Coleus*, or any other dark-leaved plant.

The three Violas may be planted as follows:—Centre, *Coleus*, or any other dark-leaved plant; next a ring of *Viola cornuta alba*; third row, *Viola cornuta*; fourth row, next the grass, *Viola lutea*. A fine effect may also be produced with *Verbena Purple King* for the centre, or a good scarlet *Verbena* or *Pelargonium*. This *Viola* seems to open out a wide field of change for the better in our flower-garden arrangements.—
J. WILLS.

NEW BOOK.

Select Ferns and Lycopods: British and Exotic, &c. By B. S. WILLIAMS, Victoria and Paradise Nursery, London.

THIS volume contains descriptions of about nine hundred species and varieties, with directions how to manage them. There are also in its pages some well-executed woodcuts, being portraits of a few of the rarer Ferns, interiors of ferneries, &c. The details of culture are full, and, we need hardly add, reliable, for Mr. Williams's skill as a plant cultivator is well and widely known. We are rather elated at being able to show our better knowledge in one point. He says that the earliest mention of Ferns with which he is acquainted is in *Shakespeare*; but if Mr. Williams refers to Lyte's "*Herbal*," published in 1578, he will find "*Filix-mas*," "*Filix-femina*," "*Osmunde* or *Water Fern*," "*Polypody* or *Oke Fern*," "*Stone Hart's Tongue*," "*Venus's beard*," and several others well described and portraited. It is quite certain, moreover, that *Dioscorides* fully 1800 years since mentions two or more Ferns under the name of *Pteris*, and so does *Theophrastus*, who lived about three centuries before *Dioscorides*.

GRIND THE TOOLS.—Keep the tools sharp or they will not cut. A dull tool wastes time, and he who permits it to work when in that condition is a dull fellow. The best turners are those who have the sharpest tools; the most successful surgeons use the keenest knives, and the most enterprising and energetic men in civil life are those whose wits have been early ground sharp, and whose perceptive faculties have been whetted by sore experience in early life. A dull tool is a useless implement, and a thick-headed unobservant person is the only one who should be found wielding it. The obtuse edge neither cleaves nor separates, but bruises and works off by attrition particles of the substance on which it operates. Grind up the tools and sharpen the wit as well; if one is keen the other will in all probability be in a similar state, from force of sympathy

alone. A boy with a dull pocket knife is one who swings on the gate, and who dodges his duty; he is one who in after-life will be a dunce and a cumberer of the ground; he will add nothing to the world of science, neither will he take from it; his existence is merely animal, his thoughts and ideas, if he has any, wholly conventional. His comrade with a keen blade,

makes models of machinery, or boats or steamers, and in time he so develops his mother wit as to be a decided acquisition to the community. Let us have all the tools in good condition, sharp, trenchant, and always ready for service; then, and then only will the result produced be equal to the time and labour expended.—(*Scientific American*.)

HULL BOTANICAL GARDEN.

I was told that Hull would soon weary me, that it well deserves its central place in the Yorkshireman's shopeforescape from "Hell, Hull, and Halifax," and that William III.'s equestrian gilded statue in the Market Place, is the object most noteworthy. So I went prepared for a lack of pastime, and I have come away with the conviction that I never was in a town much more full of subjects of interest. The unequalled fleet of steamers from all parts of northern Europe, the crowds of German emigrants, the system of unloading Wheat by hands taught to act as accurately as if moved by clockwork, the bales of Sea Grass, *Zostera marina*, for stuffing mattresses, the old brick residences—for be it remembered that here Sir Michael de la Pole revived the art of brickmaking—all, and many other objects engaged me long and gratified, so that time passed unheeded, and less than I wished was left for me to examine the Botanic Garden.

I wish that very many more such gardens were established throughout our country. No large town should be without

five hundred transferable shares of five guineas each, and the annual subscription is one guinea and a half. It is so well supported and valued that, although occupying six acres, its enlargement, or the purchase of a new site, is contemplated.

In the beds and in pots the plants are grouped according to the Natural System, and I never saw more interesting or more numerous families than some of them. For example, there were about 120 species of *Saxifraga* in pots in one group.

Whilst examining these in company with Mr. Niven, the courteous and thoroughly competent Curator, I was not a little attracted to a blind botanist led into the garden by a little lad. His name is Carey (I never knew a Carey that was not intelligent), he was formerly a solicitor practising in Hull, but became blind some thirty years since. This is a world of providential compensations, and to Mr. Carey the compensation for the loss of vision is an increase in the delicacy of the sense of touch, and in strength of memory; he sees, as it were, with the tips of his fingers, and he remembers what they reveal to him. To test this a pot containing a very small plant of *Rubus arcticus* was placed in his hands, and another in which was growing an equally small *Rubus chamaemorus*. There was something abnormal in their leaves which rather puzzled him, but he succeeded after awhile in feeling them out.

In the designing of the garden there is much skill shown in compensating for, and in obviating its flat surface; and in the details—such as the banks for Alpines, made of clinker bricks—there is much worthy of commendation; but some raised beds contrived by Mr. Niven most especially pleased me. They are oval, about 12 feet long, and about 5 feet across in the widest part. The sides, 18 inches high, are formed of slates, and kept upright and firm by cast-iron supporters of the form represented in fig. 1. These are about 2½ feet in length, with heads 10 inches broad, and a quarter of an inch thick. Painted brown, and the slates

painted stone colour, with a pendulous growing edging of Ivy or other plant, the beds must be very artistic. The supporters are placed so closely together that their heads nearly touch each other, and the boundary of

Fig. 1.

one, and they might easily be founded and sustained like that at Hull. Their value as sources of instruction, health, and amusement, are above all price.

The Hull Botanical Garden originated chiefly from the exertions of J. C. Parker, Esq., and was opened in the June of 1812. The proprietors hold among them about

Fig. 2.

the bed then has the appearance shown in fig. 2.—G.

NOTES AND GLEANINGS.

THE want of a good horticultural library has been long felt, and more especially so after the dispersion of that which the old Horticultural Society possessed at Regent Street; but now that the Trustees of the LINDLEY LIBRARY have become a legally constituted body, not only will that want be supplied by the valuable collection of books over which they will have command, but they have determined that every student in Horticulture, Botany, and kindred subjects shall have free access to it. With the view of still further increasing its utility, they also solicit assistance by presents of books or the means of obtaining these, and, doubtless, many scientific bodies and private individuals will be glad to contribute to so desirable an object. Such as may feel inclined to do so are invited to communicate to the Trustees of the Lindley Library, Royal Horticultural Society, South Kensington, London, W.

— THE Royal Agricultural Society of England having determined to hold their Show in 1869 at Manchester, we are glad to announce that the Royal Horticultural and the Manchester Botanical and Horticultural Societies will hold in conjunction with it a great Horticultural Exhibition, which promises to be on even a grander scale than that which is to be held at Leicester this July.

— AT the SALE of ORCHIDS forming the collection of the late J. A. Turner, Esq., of Pendlebury House, Manchester, on the 2nd, 3rd, and 4th inst. the biddings which the auctioneer, Mr. Stevens, of King Street, Covent Garden, obtained amounted to £2824. The following are some of the prices realised:—*Odontoglossum navium majus* was knocked down to Messrs. Veitch for £55; and the same firm purchased a fine plant of *Cymbidium eburneum* for £15 10s.; one of *Acridor Schodden*

for £30; *Dendrochilum filiforme*, £5 10s.; and *Saccolabium guttatum giganteum*, £72 9s. Mr. Williams, of Holloway, was likewise an extensive buyer, giving for *Aërides nobile*, £13; *Oncidium Lanceanum*, £6 6s.; *Cologyne pandurata*, £7 10s.; *Anguloa Ruekeri*, £8; *Angraecum caudatum*, £17; *Phalenopsis grandiflora*, £9; *Aërides Larpentæ*, £17 17s.; *Aëridea odoratum purpurascens* and *Lælia gigantea*, £11 each; *Cypripedium barbatum giganteum*, £10 10s.; *Lælia elegans*, £19; and *Cattleya Mossiæ magnifica*, £20. Among private buyers, S. Mendel, Esq., who was an extensive purchaser, gave for a young plant of *Vanda Lowii* £23; for a fine *Aërides Fieldingii*, £34; *Saccolabium præmorsum*, £10; *Lælia elegans*, £13; *Aërides Lindleyanum*, £11 11s.; *Dendrobium Falconeri*, £21; *Aërides Farmeri*, £27 6s.; *Aërides Schröderi*, £55; *A. cylindricum*, £17; *Cattleya labiata purpurea*, £31 10s.; *Saccolabium ampullaceum*, a superb specimen, £10; *S. retusum*, £23 2s.; *S. præmorsum*, £13; and *Cypripedium caudatum giganteum*, £14. R. Warner, Esq., W. Agnew, Esq., Mr. Dixon, Mr. Parker, J. Day, Esq., of Tottenham, Dr. Ainsworth, T. Salt, Esq., and Mr. Medley, also gave liberal prices; but to attempt to enumerate more than a few out of nearly eight hundred lots would occupy more space than we can afford.

— Mr. J. N. LEE, who has been for some years the Sub-Editor of our valuable contemporary, "Bell's Weekly Messenger," is a candidate for the Secretaryship of the Royal Agricultural Benevolent Society, vacant by the resignation of Mr. Shaw. We sincerely trust that that excellent Charity may be fortunate enough to secure the service of a gentleman in every way so qualified to promote its prosperity as Mr. Lee.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Broccoli, get as many as are ready planted out. Like all hardy seedlings this season they soon crowd each other in the seed beds. Do the same with *Cauliflower* and *Cabbage* plants. *Beans* and *Peas*, except for the earliest crops of these, people seldom think of stopping them; but they should all be stopped if only to keep them within reasonable bounds. Sow successions of *Herbs*, such as *Basil*, *Chervil*, *Parslane*, *Parsley*, &c. It is a good plan to sow plenty of the latter in a quarter of Gooseberries or Currants, as it will be found useful in February and March, when to be scarce of Parsley is very awkward. *Endive*, plant out a few of these for the first supply, and a few more ten days hence, after which they will enter among regular succession crops. *Onions*, these have grown so fast lately, that unless they are well thinned out they will injure each other. Sow also *Turnips* and *Radishes* for succession; the last crop of *Broad Beans*, *Marrow Peas*, and *Scarlet Runners*, and *Dwarf Kidney Beans* for succession. One crop of the last might be sufficient all the season if the ground were well manured, the plants supplied with water, and no pods allowed to become large for seed. Plant out *Herbs*, such as *Basil*, and *Marjoram*, in a warm situation, and *Cabbages*, *Savoy*, *Brussels Sprouts*, and *Celery*, the last named in trenches, also in beds for future removal, shading the latter. *Sea-kale*, and *Asparagus*, fork up the ground of the beds; give them a dressing of rotten manure, a moderate sprinkling of salt repeated at intervals, and a good watering of drainings from the dunghill, if you can afford it, and your beds are not in a damp situation.

FRUIT GARDEN.

This is about the best time to scarify the branches or stems of hide-bound trees, a good old practice which has fallen into disuse, probably from being performed in winter, when it did more harm than good, by opening up wounds which could not be healed till the return of the sap next summer; but if performed now, the incision will be filled up in two or three weeks with a layer of soft matter from top to bottom, along which the returning sap will find a ready channel to the roots. Just try a branch or two this way, if only for experiment. I am satisfied from experience that it is a safe and useful plan to invigorate stunted branches, but it must be done at the right time. Proceed with thinning, nailing, and tying-in young shoots. There will be a fair crop of *Apricots* and *Peaches* in most places this season. Guard against leaving too much fruit, and too many shoots. It is advisable neither to exhaust the tree by over-cropping, nor to allow more wood to remain than can be properly ripened. In unfavourable situations, after seeing that the borders are not suffering from drought, keep them clean and smoothly raked near the wall, or cover them to the width of a yard with tiles; the reflection of heat from the tiles, and

keeping the borders rather dry, will insure the earlier maturation of the wood, but if the soil be allowed to become soaked with rains in the autumn, all the extra labour will be worse than thrown away.

FLOWER GARDEN.

About the beginning of June is generally the time for budding *Roses* that are wanted to push into heads this season, such as we call Monthly *Roses*; but already we are in the beginning of the month, and hardly a bud can be inserted as yet, the wood of both bud and stock being so green and soft; it is also time to begin to put in cuttings of all the China and Climbing *Roses*, taking the young stubby shoots which form along the main branches, and are about 4 or 5 inches long. These are now nearly ready for making into cuttings, and simple as this process is, there are many who do not know it. Except where American plants are mulched, they must receive a thorough deluge of water, by forming basins round them, and afterwards covering the wet soil with dry earth or some kind of mulching. Those who have *Roses* in pots may now use them advantageously for budding, and on the Tea and China varieties will obtain growth, and probably flowers in the autumn. *Auricula* and *Polyanthus* seed will now be becoming ripe; as soon as the capsules assume a brown colour, and give indications of opening, they must be gathered. Dry them well and put them in small tin boxes. Put a glass shade over the Tulips, the seed vessels of which are intended to be saved, to prevent the wet lodging in the apex. Those bulbs, the leaves of which have suffered from canker, or have sustained injury from early frosts, may be taken up, as they are apt to mildew if allowed to remain in the ground too long. Carefully shade the *Ranunculuses* intended for exhibition; semi-double flowers for impregnation must not be covered, as the sun and air are essential in the process of fertilisation. Water the paths about the beds so as to make the surrounding atmosphere as moist as possible. Wetting the foliage at this season, especially with spring or hard water, is rather detrimental than otherwise. Continue to tie *Carnations* with soft worsted; examine those previously fastened, and see that the tie is sufficiently loose on the stick to allow the stem to elongate. Thin out the buds, the crown or topmost bud usually produces the largest and best bloom. If the plant is strop, reserve five, on the contrary three are sufficient if the plant is weak. Pinks are not generally lazing well this season. Pippings must be kept regularly moist, and well protected from the direct rays of the sun. Continue to put in cuttings of Pansies.

GREENHOUSE AND CONSERVATORY.

Of all the great families of conservatory plants, the Chinese *Azalea* has made the most rapid improvement in size, shape, and colour, and being amongst the easiest to force early in spring we may have some of them in flower for this house from the end of January to this time. In ordering them from the nurseries, amateurs who are not well versed in the cultivation of plants should order "worked plants," while some gardeners prefer them on their own roots, in order to keep them dwarf for particular situations; but they are much more easily managed when grafted, and this is a good time to graft them. I would strongly recommend, when young plants of *Azaleas* are brought in, that they should be turned into a bed of sandy peat in a turf pit or common cold frame for the next three or four months; they can always be removed with safety into pots. The general routine of watering and training greenhouse plants, with attention to cleanliness, is all that needs attention now, unless some of the plants may want another shift. It might be worth while to mark such plants as flower from April to June that may be becoming too large or straggling, and are not in good health. Keep them in a warm sheltered place, and when winter-forcing is begun take them in to see how early they can be flowered. In very many cases plants in flower do not require so much water as when they are in more active growth; but the strong-growing conservatory climbers planted out in the borders can hardly have too much moisture now.

STOVE.

Besides the daily routine of watering, shading, giving air, and training the plants, with an occasional shift to some more promising specimens, there is little to be remarked on just now. The great fault in almost all plant houses is their being too full of plants, and consequently the plants injure one another; but as a number of stove plants are much benefited by a change into some of the cooler houses, this house never need be injuriously crowded in summer.

FORCING PITTS.

The young stock of Gardenias, with all the novelties recently propagated, are the chief occupants here; and now begins the propagation, by grafting, of Camellias, Rhododendrons, and Azaleas. Where expedition is preferred these may be kept in a strong, moist, and close heat till the grafts are united; but they will do perfectly well in a close cold frame well shaded, only they take longer time.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

HERE, with the exception of planting Cauliflowers between rows of early Peas, where the former would be protected by the shade of the Peas, no planting was attempted, as the ground and the atmosphere were alike dry. We have read of storms and downpourings of rain, north, south, and all round us, but up to this, the 6th of the month, we have had only a few drops of rain in our district; and though established crops in the kitchen garden stand well, especially when assisted with mulching, it would be useless to transplant much, unless shading of some kind were given. In such weather garden pots afford good shading for a few days to all the Cabbage tribe, when the plantations are not extensive, removing the pots at night, and replacing them before the sun becomes very powerful. As much watering with us is entirely out of the question, we neutralised the excessive heat and dryness by surface-hoeing with the Dutch hoe, and mulching Cauliflowers, Peas, &c., with litter and short grass.

During the last days of the week the atmosphere was very dry with us—a fact we arrived at by no scientific instruments, but from the simple observation, that though there was a fierce sun all day, and a clear sky the most of the night, there was next to a complete absence of dew in the morning under the very circumstances in which we would have expected abundance, if there had been much vapour in the air near the ground to be condensed into dew. In such a state of things we forbore planting Celery and other crops, as it was much easier to water where the plants were close together in beds, than to spread the watering over a larger surface.

Potatoes.—Partly from press of other work, and partly on purpose, we have earthed-up but little. If planted 6 inches or more from the surface, Potatoes are little better of the earthing-up. In very dry seasons they are the worse of it, as the roots do not obtain enough of moisture, especially when the ridge resembles the point of an acute-angled triangle. In very wet summers and autumns, we think the ridged-up Potatoes are less liable to the disease. In loose, open soils, we do not see much use in the earthing-up, so as to make an open gutter between every two rows.

Weeds.—The hot weather made these grow so fast that we gave up bedding-out in the flower garden on the Saturday, in order to have at least one day's cleaning and surface-hoeing. It is bad policy, if it can be avoided, to permit seed weeds to require to be treated with anything but the Dutch hoe. In such weather as the last days of the week, ground hoed shallow will not only have a loose surface, but every weed cut up will soon disappear under the drying of the sun, and multitudes of weeds would be destroyed by the hoe that could scarcely be discovered with the eye. Weeding by the hand should be avoided as much as possible.

FRUIT GARDEN.

Very much the same as last week. Mulched our fruit trees in pots heavily so as to save watering, which the mulching does very much. In this case it chiefly consisted of rather fresh horse droppings, and a little litter, rather fresh, which had been in a heap for ten days, and heated violently. We used the centre of this heap, after passing it through a rough open sieve of rather more than 1-inch mesh, to exclude the longer pieces of litter. We know we lost fertilising power by this heating, but we killed all the ants that might have been in the droppings, also the stray seeds of Wheat that might have been in the straw for litter; and if this is not done, mulching with such material will provide plenty of future work in weeding the surfaces of the pots. Just now, and before we get our tanks replenished, we must be very economical of water.

Strawberries.—Some idea of the dryness may be formed from the fact, that blackbirds and thrushes, which have visited us in clouds this season, have begun their ravages on Cherries and Strawberries which are yet quite green out of doors. It is not likely that we shall gather Strawberries out of doors for

a week at least, but the berries of Keens' Seedling, &c., are of a good size though quite green, and great numbers of these are picked and eaten, a sure proof that the birds can obtain no other juicy food. In such weather old gardens generally suffer greatly, but a good rain relieves them for a time from the birds, as the latter then find succulent food elsewhere.

We have now removed most of the Strawberries from under glass, except in the front of the orchard houses, where they have done good service, and where we hope to gather until we have them out of doors, if we can keep the birds from them. The blackbirds helped themselves to some fine fruit of the British Queen in the Peach house, forcing us to net the openings for ventilation. From having a fair amount of light and air, the Strawberries in the orchard house are almost as good in flavour as when grown in the open air, and better than out-door ones in dull and drizzly rainy weather. All Strawberries are best the fresher gathered they are, as a general rule, but to have the full flavour they should be gathered dry. Those picked in the morning will be more juicy; those gathered in the afternoon after a sunny day will be more sweet and better supplied with saccharine matter. When we have wanted Strawberries early in the morning, before they would be dried after a dewy night, we have found it a good practice to gather on the evening before whilst the fruit and leaves were quite dry, and place the fruit thinly on fine paper for the night. This may be of use to those who wish to have their Strawberries at the best. The best fruit are comparatively insipid when gathered out of doors after a rainy day. Sun and dryness are necessary for flavour.

ORNAMENTAL DEPARTMENT.

Lawn.—We have used the daisy knife several times, just to make all look green. A few tough bents appear here and there to take off the uniform level, when examined close at hand, but looked at from a little distance the grass appears as well as if mown and swept several times. We shall be very unwilling to mow until rains come. All is now green; but if closely mown and another week of parching weather should come, we should expect a brown surface instead of a green one. The only disadvantage of the knife, instead of mowing or machining, is that we shall be obliged to use the scythe instead of the machine, and that will take more time at the first going-over. No flowers on a lawn will compensate for the want of greenness, and many a lawn might be green instead of brown but for the merciless cuttings it is subjected to in hot parching weather. The mere knocking-over of Daisies and Plantains, &c., is very different from cutting down so short in such weather the tender blades of grass. Better, in our opinion, have a green surface if not quite so short. If some of the grass should be 2 or 3 inches in height there will be no trouble in walking on it in dry weather, and when wet comes it will be easily mown, and then the machine may be used, though even then we like to employ the scythe occasionally, as it keeps all more level and nice at bottom.

Planting.—Gave up on Saturday owing to the excessive dryness, and much hoeing and cleaning being required. Deferred planting lots of annuals from the same cause. A little delay in such cases is often as good as too much forwarding. "What! not done planting yet?" has now no terrors for us as it used to have. What is planted is standing the test of the weather well. The plants were well watered at the roots, and the dry earth replaced on the surface; and though most of them were not turned out of pots, but lifted from earth beds in which they had been planted, they showed but little distress with all the bright sun until the 6th (Saturday), and instead of watering, the syringe and the garden engine were employed, just to spirt over the foliage and ground, on which the water did not rest long, but it arrested evaporation from the plants, and what was spilt on the ground refreshed them, too, as it rose again into the atmosphere, and by the evening every leaf was as erect as possible.

Such damping of foliage can scarcely be called watering. Many would be afraid to do so. Counsels out of number are given never to water, and, above all, never to wet the foliage of a plant when the sun shines, or dire were the results that were sure to follow, in scalding and burning even out of doors, if the sun shone on damped foliage. At present we say nothing of plants under glass, though even there, if the glass is good, no burning spots in it, and there is plenty of air to prevent condensed vapour, the danger in many cases is more problematical than real, but out of doors we have never noticed this wondrous scalding and burning. On the other hand, we have often noticed how gorgeous and lovely vegetation looked when after a heavy sunny shower, the sun came forth and all vegetable nature seemed to rejoice, instead of being in the least

sensitive to approaching danger. Will any of our observing readers tell us of instances within their knowledge in which vegetation was blighted and scalded after a sunny shower? So much for matters in the extreme. Our readers know well that we disapprove of watering in sunshine when it can be avoided. On the same principle, after this season it will be best to water during the afternoon and evening, as the plants then slowly and leisurely absorb the water and derive the benefit of it. When watered in the morning, the sun takes the moisture all away too quickly. We prefer watering house plants in the morning from the middle of October to the end of April, where no very high temperature is maintained, as the watering will always tend to lower the temperature, and that is best met by the rising temperature of the day, instead of being decreased by the waning temperature of the night. We have gone, however, from our starting point, which was merely to hint that newly-planted subjects out of doors in very bright days may often be benefited by a sprinkling overhead, when deluging at the roots would hardly have the same result, if they are wet enough already there; and it is certain that one pailful of water will do as much good over the foliage, when put on as a fine bedewing, as twenty pailfuls would do at the roots.

We intended saying something about cutting flowers, the advisability of having plants for show, and plants for cutting from, and a definite place for each; also, on the moving of plants when done flowering, as Camellias, Azaleas, Epacrises, and Heaths; on pruning the latter two, and never cutting into the old wood, unless rarely, however short be the spur left of the last year's wood; the importance of a suitable place for all these plants, and when young the importance of pits, and better still of wooden boxes for such purposes; the superiority of the wooden box being that not only can you give air top and bottom as in a pit, but by setting the box on a brick at the corners you can also have a free circulation of air beneath, and through among the pots as well as the tops of the plants. Unfortunately such matters must wait, but much that we intended saying will be found in the last articles of Mr. Keane, to which we would refer our readers, as many details are there carefully given.—R. F.

COVENT GARDEN MARKET.—JUNE 10.

VERY little variation is to be noted here. Supplies are ample, and there are large quantities of Strawberries from the open air. Old Potatoes are almost superseded now by the new ones. The latter from Lisbon bring from 15s. to 20s. per cwt.; Ashleaf, from 18s. to 22s.; Cornish, from 12s. to 15s.

TRADE CATALOGUE RECEIVED.

James Veitch & Sons, Royal Exotic Nursery, King's Road, London, S.W.—*Catalogue of New and Beautiful Plants.*

TO CORRESPONDENTS.

FLOWER BED IN A CHURCHYARD (*Churchyard*).—Your semicircular bed would look well thus arranged—white *Cerastium* outside border, then

blue *Lobelia*, yellow *Calceolaria*, and *Perilla* for the centre; or a pretty bed might be carpeted with *Mignonette*, and dotted with little groups of white *Pelargoniums*.

SEEDLING ANTIRRHINUMS (*J. Carter*).—There is nothing new among your seedlings. One, a large yellow variety, seems the best and would be worth cultivating. The others resemble many other seedlings.

LETUCE FOR WINTER AND SPRING (*H. C.*).—For use late in autumn and early in winter you may sow in the middle of July, but the main winter sowing should take place in the second or third week in August. Another sowing made three weeks later may be useful for spring if the winter be tolerably mild.

AMMONIACAL LIQUOR (*J. H. W. Bunbury*).—That referred to in the work you name is the same as the liquor from the gas works, but it varies in strength, and must, therefore, be used with great caution even after being diluted with several times its bulk of water. We would not recommend its application to a Vine border.

GRAPES DESTROYED (*J. R. Boydell*).—The berries you enclosed were destroyed by what gardeners call "the spot." We believe it to be occasioned by the growth of the Vine and its crop being faster than the roots can supply sap to sustain. Keeping the roots warmer, and the house rather cooler and freely ventilated, are the most effectual remedies.

GRAPES (*Nottinghamensis*).—The Muscat E-chokata is a synonym of the Muscat of Alexandria. Fertilisation should be assisted as recently directed. We do not know the book on Vines which you mention.

DURATION OF A VINE BRANCH'S PRODUCTIVENESS (*Jersey*).—The time that a Vine stem on the spur-pruning system will continue to produce fine fruit depends entirely on circumstances. We have known Vines thus produce without any signs of decay for between twenty-five and thirty years. We have seen others that seemed as if they needed the stimulus of fresh wood in five or ten years. In our own practice we seldom renewed such a stem at once. We would begin by leaving a shoot at the base one summer, which would fill a third or a half of the length of the latter next season, the spurs on the old stem being cut off for that length; and only when we had a new stem and shoot to reach the top of the house did we entirely remove the old stem. This is a good plan for renewing the strength of old Vines, and there need be no interruption of crop. The only difference in treatment is, that there are few laterals left on the bearing shoots of the old stem, but more strength is thus thrown into the young shoot, which keeps up a good root action.

VINE LEAVES BROWNED (*Mrs. M. S.*).—The Vine leaf has the signs of scalding with hot vapour, and early air-giving is the remedy. As only one Vine is affected, and one side of your Peach tree, we think as the latter is undoubtedly burned, so the Vine may also be burned. Examine the glass carefully, and you will be sure to find some scars and faults, and dabbing them with white paint will prevent the burning the Peach leaves.

MOLES IN VINE LEAVES (*E. S. Chelsea*).—The mode of planting the border and general management have nothing to do with the hole and eaten appearance of the Vine leaves. This is done by weevils, which you must watch for at night. If you spread a sheet beneath the leaves and shake them at midnight, you will most likely see some of your visitors drop. After thus clearing the Vines, fix some wool or wadding dipped in oil and turpentine on the stem of the Vine near the ground, to prevent them getting on the Vine so easily. We know no method of extirpating them except by night-watching.

VINE BLOSSOM INJURED (*Black Hambro*).—Your Vine blossom has been scorched by the late excessive heat before it was enabled to be developed. There does not appear to be any disease.

DEODORISER FOR SEWAGE (*Opponax*).—Powdered charcoal, gypsum, and chloride of lime (more properly called chloride of calcium), are all deodorisers and might be added to the sewage. They would promote rather than injure vegetation. The earth itself is a powerful deodoriser; and if you dig-in the sewage, or poured it into the trench made by the spade and covered it with the next spit, the offensive smell would at once be removed.

GAS AMMONIACAL LIQUOR (*A. B. J.*).—The proportion depends entirely on the strength of the gas water. We should be afraid to use it strong, better be on the safe side.

MANAGEMENT OF MANETTI ROSE STOCKS (*Wylie Green*).—"Manetti stocks cannot be planted too shallow if they are rooted plants; neither can they be budded too low. For this purpose it is best to plant them in shallow trenches. It is preferable to bud them on the main stock; but they may be budded low on one or more branches if so desired. It is usual to leave one shoot growing and to cut the others off. This may be done when winter sets in, or in the spring. I bought last winter a lot of Manetti Roses in dormant bud with the plants cut down. I planted them in a trench, filled the trench with stable litter, and closed with earth over the litter loosely, so as not to exclude the air from the concealed buds. They are now growing beautifully. If you wish to increase your Manetti stocks by cuttings you may, without injury, let all the shoots stay on till you wish to plant the cuttings in September. The cuttings should be 10 inches in length, and planted 6 inches deep, a leaf or two being left on the tops of the shoots. They should be trodden-in firmly, and horse litter or straw placed among them. After the shoots have grown long they may be stopped by pinching off the tops. With regard to Briars, where wind does not prevail, or where the shoots are not so heavy as to break themselves down, they may be left on. It is, however, safest to cut them back to 10 inches. Before budding water all kinds of stocks well, and after the stocks are budded, if the weather is hot and dry, it is a good plan to tie a deck or some other leaf over the bud to act as a temporary shield. If Manetti stocks are budded early, as soon as the bud has taken and swells you may cut off the shoot of the Manetti to within 3 inches of the bud, and flower the Rose in the year of its budding; but it is not good to do so late in the season.—W. F. RADCLIFFE."

BUDDING ROSES IN JUNE (*A Budding Greenhorn*).—"Fig. 1 in page 391 is a view looking down on the top of the stock, and what appears to be a Rose is the grain of the wood. The budding knife is shown in halves, because both ends are made use of—the blade in fig. 2, and the handle, which is of bone, in fig. 1. These knives can be procured at any seed shop.—T. J. S."

ROSE FLOWERING ONCE IN TWO OR THREE YEARS (J. Allen).—We do not know the Rose that blooms only once in two or three years. Some strong-growing Roses will not bloom if pruned closely; but if several long shoots are left and are well ripened, small flowering shoots will come from every bud on these long shoots in the following year. This may be the case with your Rose. Sow the Walcheren Broccoli now.

CUCUMBER PLANTS IN BOXES (Lancashire).—At this season we should have liked boxes larger than 14 inches by 10 by 9 for Cucumber and Melon plants, but they will do, only they will require well watering. As soon as established, use weak manure water and frequent mulchings with sweetrotten dung. We have had such boxes topped up several inches above the rim with mulching.

CUCUMBER LEAVES FLAGGING (Whit Monday).—Less heat, more air, and less moisture will benefit the Cucumbers, and render them less liable to injury from the sun. We do not like the brushwood and long dung over the pipes for bottom heat. Either the roots go through it and are scorched, or the heat will not rise freely.

CACTI NOT FLOWERING (Idem).—Expose the Cacti under glass as much as possible. In August set them out in front of a fence facing south, and give no water except what is wanted to keep them from shrivelling.

CUTTING OUT AN OLD VINE ROD (Idem).—If you do not care for the fruit on the old stem of the Vine you may cut it away now, to strengthen and afford space to the young shoot which you intend to take its place, more especially as that already reaches the top of the house.

MEDINILLA MAGNIFICA (Idem).—It is a native of the Philippine Islands.

PELAGONIM LEAVES DISEASED (H. H. T.).—We think the leaves withered have been scalded by condensed vapour about them when the sun shone on them. We recommend a drier atmosphere and plenty of air, so that the foliage may be kept dry. Some of the holes resemble those made by spot, and the above is the best cure and preventive. Others look as if they had been nibbled by weevils; and these insects must be looked for at night, or tempted with something sweet, as sugar and arsenic.

STRAWBERRY PLANTS BARREN (Dr. Dixon).—As this is the second season such numbers of your British Queen Strawberry have proved barren, we would remove the plants and save runners from those that are fruitful. We saw a fine bed of British Queen last September twelvemonth. The plants were then heavily mulched with rich manure, and were receiving strong manure-waterings. Comparative dryness would have been better. The plants grew very fast, but they yielded scarcely any fruit last season. Left alone, about half are showing bloom this season. If the barrenness is from overfeeding last year you may try again; but if not, we would remove the barren plants.

DESTROYING SCALE ON PEACH TREES (Subscriber).—Scrape the trees with soft-soap water, one ounce to the gallon, using it at 90° or 100°, and next winter apply it to the trees as hot as possible. The ants like the scale and other insects, using them as we do a milch cow. They do no harm to the tree, but woe betide your fruit when it ripens. See late numbers for modes of trapping and destroying ants.

PEACHES MILDEWED (C. P.).—Your Peaches are mildewed. Apply flowers of sulphur, and give plenty of air.

TRAINING RED CURRANT TREES (E. M. B. A.).—Red Currant trees will be much benefited by being pinched back now, just as you propose for dwarf standard fruit trees. Perhaps the best way of growing them and Gooseberries is espalier fashion to a strained wire trellis. A quantity of fine fruit may thus be obtained, and the ground round or between the trees may be cropped.

CLIMBERS FOR AN EASTERN ASPECT (J. S.).—Any of the hardy Clematis, Honeysuckles, and climbing Roses will suit you.

CLIMBERS AND PLANTS FOR CONSERVATORY (A. H. F.).—A few good climbers for a conservatory are Clematis Fortunei, double white; C. lanuginosa, lavender; Soliya linearis, blue; Kennedya inophylla floribunda, blue; Lapageria rosea, rose; Passiflora racemosa rubra, reddish; Rhychospermum jasminoides, white; Tropaeolum Triomph de Gand, orange; and T. tricolorum, orange and yellow. Of plants you may have Camellia Fimbriata, white; Lecana superba, crimson; Stori, rosy pink; Valletaria, rose; and Queen of Beauties, bluish, veined with pink; Azalea Cheloni, orange scarlet; Gleditsia formosa, white, striped and blotched with scarlet; Etolo de Gand, shaded salmon; Queen Victoria, white, striped and spotted with purple; Criterion, salmon pink with white edge, and spotted with lake; and Mars, orange scarlet. Of other plants the following would be suitable:—Epacris Lady Penmore, The Bride, and Hyacinthidors; Acacia longiflora magnifica, A. oleifolia elegans, and A. Drummondii, all yellow; Chorozoma cordatum splendens, brownish orange; Correa Brilliant, scarlet; Cyclamen persicum; Eriosemon intermedium; Dracophyllum gracile, white; Epiphyllum Russellianum, salmon; Inanophyllum minutum, orange and yellow; Indigofera decora, bluish purple; Kalosanthus coccinea superba, rosy red; Monochlora ensiferum, rosy purple; Pimelea Hendersoni, pink; Polygala Palmatensis, purple; Rhododendron jasminiflorum, white; Statice brassicifolia, lavender; and Valletta purpurea, scarlet. We hope we have not named too many, but you may reduce the number, and add to them by plants from seed, which may now be sown, as Cinerarias, Calceolarias, Fuchsias, Petunias, Primulas, and Pelargoniums. These will flower finely in the spring and summer of next year, and you may add to them by sowing next spring such annuals as Balsam, Cockscorn, Globe Amaranth, Celosia pyramidalis, and other tender and half-hardy annuals.

LAUREL CUTTINGS (L. A. S.).—Laurel cuttings should be put in at the end of September, and not later than the middle of October. The cuttings should have an inch or two of the old wood in addition to the growth of the current year, and be inserted two-thirds of their length in the soil, which should be made firm about them. Scarcely a cutting fails.

CUTTING-BACK BROOM (Idem).—Broom may be cut back as soon as the flowering is over, but leave some portion of the young wood to furnish new shoots, for if cut-in to bare stumps old plants sometimes die. The above remarks apply equally to double-blossomed Furze. Old plants are best replaced by young plants.

ROSE CUTTINGS (Idem).—Put in Rose cuttings in July, just when the shoots have shed their flowers; place them in a frame, and keep them

close and shaded until rooted. It is a successful mode of propagation. You will find an answer to your other question in "Our Letter Box."

PLANTS FOR SPRING BLOOMING (M. E. M.).—If you now procure good plants of the Cliveden Pansies you may by making every available portion into a cutting, and continuing propagation up to August, secure enough plants for two small beds. We should plant them in the beds as early in October as the removal of the bedding plants will allow, but planting may be deferred until March; then remove the plants with a good ball to each. The seed of Silene pedicularis should be sown in the end of September, and the seedlings pricked-off in a warm situation when large enough to handle, and planted out in spring; or they may be planted out in autumn on the removal of the bedding plants. The seed of Myosotis sylvatica should be sown now in light sandy soil, the plants being pricked-off when large enough to handle, and removed to the beds in autumn or spring with a ball of earth to each.

REMOVING LARGE EVERGREEN TREES (T. N.).—We have little hope of your removing a Cedar of Lebanon 30 feet high and 3 feet in circumference at 1 foot from the ground. The tree may probably be moved at great expense and with great difficulty by hand power, and though it would be more easily moved by machinery, we are very doubtful of its ever thriving afterwards; indeed, we would much prefer planting a young tree, which we know from long experience would after some years make a handsome tree than one removed. We have never known a Cedar of the size and kind you name do any good after removal; but we have seen many instances of supposed successful removal, in which after a few years the trees became unsightly objects. The removal of large deciduous trees can be effected with greater safety and prospect of growth afterwards than that of such trees as the Cedar of Lebanon, which make roots very distant from the stem. The removal of large evergreen trees is best effected in summer as soon as the growth has become firm; there is the best time to move all sorts of evergreen trees and shrubs, both young and old, and the transplanting of deciduous trees is best performed when the leaves are falling. The moving of all trees and shrubs is facilitated by taking out a trench round them in the autumn or spring preceding that in which they are transplanted.

REMOVING SHRUBS (J. B.).—The best time to remove the Thorn would be as early in November as the leaves assume their autumn tints. The Cypress and Arbor Vites would be best removed as soon after the middle of September as the weather is cloudy and showery. In removing them care should be taken to preserve to each a good ball of earth, and to retain as many roots as practicable. Digging a trench round them should have been done before growth took place, and fully twelve months previous to the contemplated lifting. In case your shrubs make but little growth this summer their removal had better be deferred until next April, except in the case of the Thorn, which should be removed in November.

LABURNUM WITH VARIOUS-COLOURED FLOWERS (W. Boyd).—It is Cytisus Adami, and was originally produced upwards of forty years ago in budding Cytisus purpureus on the common Laburnum. In this process it is supposed that a cell of the one species became divided and united to a cell of the other, and the result has been a plant producing not only flowers of each species separately, but others partaking of the characters of both. There are other instances in the vegetable kingdom in which a similar union of cells is believed to have taken place, but Cytisus Adami is the best known and best established. The subject has been referred to several times in the volumes of this Journal.

PAINTING FLOWER POTS (Clay).—See what "G. S." says to-day.

WATER WEED (C. H.).—The water weed you enclosed is Conferva floccosa, but we cannot say how you are to get rid of it, unless perhaps by emptying the pond; and, as the bottom is concreted, give it a good dressing of salt.

PROPAGATING CLEMATISES (J. M.).—The present time is not the best for the propagation of Clematises, but the operation may be done now, the shoots being layered when the wood is about half ripe. A small pot should be one-half or three-parts filled with sandy loam, adding a slight admixture of sandy peat and silver sand. The pot should be sunk in the ground to the rim, and the shoot to be layered should cross the pot at a joint, which should have a small slit cut in it with a sharp knife, as in layering Carnations; but on account of the smallness of the shoot of the Clematis the cut must be of less depth and length—indeed, it will be enough if the shoot be slightly cut immediately under the joint. The shoot may be laid across the pot and secured at the joint with a peg; then fill to the rim of the pot with fine soil. The part of the shoot beyond the pot may be tied to a stake placed in the pot, and in dry weather give water to keep the soil moist. The shoot will most likely be well rooted by autumn, when it may be detached from the old plant. If no shoots are situated near enough to the ground to permit of the layering in a pot sunk to the ground, the pot may be raised and the shoot layered, only the pot in this case will require constant daily watering in summer. Cuttings of the half-ripened wood inserted now in pots filled with light sandy loam and peat, and placed in a cold frame or pit, and kept close and shaded from bright sun, would in all probability root well. The cuttings should have two good joints, one of which should be inserted in the soil, but some Clematises are only to be propagated by layers.

NAMES OF PLANTS (O. Z.).—1 and 3, Asplenium bulbiferum; 2, A. filicidum; 4, A. lucidum; 5, Davallia sp.; 6, Gymnogramma tartarea; 7, G. ochracea. (T. P.).—Not possible to name such young specimens. (A. Subscriber).—Combretum racemosum. (M. H. R.).—Carex pendula. (Mr. Cobbett).—Crataegus pyrifolia. (T. Pearson).—1, Cotoneaster rotundifolia; 2, Eucalyptus europaeus. (F. G. Sherrin).—Lastrea dilatata. (W. H. M.).—All Cystopteris fragilis. (W. B. S.).—The Glanders Rose, Viburnum opulus, a native of England. (H. E. S.).—We cannot name plants from leaves only. (A. B.).—We cannot identify Saxifragas, nor any other plants from their leaves only. (G. A. S.).—2, Pteris flabellata; 3, Cyrtomium falcatum; 4, Adiantum diaphanum; 5, Blechnum occidentale; 6, Asplenium bulbiferum; 8, Doodia cordata; 8, Davallia novae-zealandiae; 10, Onoclea sensitiva; 11, 12, 13, Cystopteris fragilis; 14, Nephridium exaltatum; 15, Athyrium filix-femina. (Pteris).—Melittis melissophyllum. (J. A. Boyd).—Polypodium dryopteris. (J. W. Dick).—1, Neottia nidus-avis; 2, Galium cruciatum; 3, Anthriscus sylvestris; 4, Lychnis dioica. (J. Scott).—Saxifraga elatior. (T. B. W.).—1 and 2, bad specimens; 3, Habrothamnus fasciculatus. (T. C.).—1, Erius alpinus; 2, Veronica chamaedrys; 3, Chrysosplenium oppositifolium. (E. D. S.).—Onosma stellatum. (J. C. G.).—Menyanthes trifoliata.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending June 9th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

GAME FOWLS IN FORMER YEARS.

THE most celebrated breeders of the last generation were the following titled persons, as I have read—viz., the Duke of Leeds (about a hundred years ago); the Earl of Derby, Knowsley Park, Prescott; the Earl of Mexborough, Methley Park, near Leeds; the Earl of Lichfield, Sloughborough Park, Staffordshire; Lord Hill, Hawkstone Park, Shropshire; Lord Ongley, Old Warden Park, Bedfordshire; Lord Huntingfield, Heveningham Park, Suffolk; Sir Harry Goodricke, Bart., Studley Castle, Alcester; Sir George Sitwell, Bart., Renishaw Park, Derbyshire; and Sir Thomas White, Bart., Tuxford Park, Notts.

Charles II. patronised the cockpit, and amongst other colours was partial to the Black and Brassy-winged Black Game fowls, a colour now generally thought both too slow and too soft to be very good. King Charles frequented the Royal Cockpit at Whitehall and the Newmarket Cockpit.

The Duke of Leeds above mentioned had a very strong and powerful breed, called the "Shackbags," or "Shakebags," now extinct, having been latterly crossed with the large Malays and entirely spoilt thereby. The Duke's men used to bring their birds to fight in large bags, shaking the bags, and challenging all comers to single battles, in which the great size and power of the Duke's breed generally gained the victory. These birds were too large to fight in mains, and were fought in the "byes" and single battles, against the "catch weights" and "turn-out" birds.

The Earl of Derby, as previously mentioned, bred the white-legged Black-breasted Reds with yellow or daw eyes, and this breed was more than sixty years in the Stanley family, and the birds were called the "Derby Reds."

Lord Hill, I have been informed, bred the Silver-Grey breeds, both Dark Silver-Greys and Silver Duckwing Greys. Lord Huntingfield bred, as before stated, the white-legged Duckwings with yellow or daw eyes. The Earl of Lichfield had a breed of "Tasselled Spangles" amongst his other colours, which were in existence in 1832, but are since bred out. Sir Harry Goodricke, I think, had the Brown Reds.

The greatest patrons of the Royal Cockpit, Tufton Street, Westminster, were the Earl of Derby, Lord Ongley, and Mr. Germaine, the latter gentleman more especially so, and the feeders principally employed there were Gilliver, Potter (for the Earl of Derby), Nash, Leicester, and Walters. The favourite fighting weight was 4 lbs. 8 ozs., or 10 ozs., 2 ozs. over 1½ lbs. being allowed, and the cocks were as large-framed, light-fleshed, and long-reached as possible at this weight, or as "fine March cocks" as possible at the weight allowed, which birds are the fastest fighting of all.

The middle of the reign of George IV. was about the greatest era of cock-fighting, and the qualities of the best strains of birds were then best developed. Brown Reds were most used, and then Cheshire Piles, Dark Greys, white-legged Black-breasted Reds, and willow-legged Duckwings. These were the five most common winning colours that have the most beaten the common willow-legged Black-breasted Reds, which, with Blacks, were considered losing colours, and so were most other colours, with some exceptional strains. The north country hen-tailed cocks were often fought in the "byes."

Mains of cocks were generally of three descriptions—first, the royal main, or main royal of twenty-one cocks on each side, or forty-two cocks in all; second, the main of fifteen cocks on each side, or thirty birds in all; and thirdly, the main of seven cocks on each side, or fourteen birds in all, which

was, perhaps, the most common, and consisted of the most select birds. There was the Welsh main, also, of sixteen cocks in all, the eight survivors pitted again, four against four, and again two against two, and the two survivors again, one against one. Thus the winning cock had to win four battles. This was of course the hardest sort of fighting of all, and only really good hard birds like Brown Reds and Dark Greys could generally win Welsh mains, but the hen-tailed cocks did sometimes win them. In the royal mains some splendid Brown Reds used to be seen, this bird being the acknowledged favourite colour of almost all sporting gentlemen, and for the pit the most cultivated of any colour—in most localities at any rate.—NEWMARKET.

ENTRIES IN VARIETY CLASS.

I WANT the opinion of yourself and my fellow exhibitors as to entries in the variety class, and although a personal matter, yet as the case is one much in point, I state it.

At the Falmouth Bath and West of England Meeting, of which you gave a report last week, I received a high commendation in the "Any variety" class for Malays, White Spanish receiving a prize, whilst there was a class for Spanish without any limitation of colour. Query, Were the White Spanish wrongly entered? and if so, ought they not properly to have been disqualified?

At Weston-super-Mare Show, I think—if not there, at Clifton—a pen of Black Cochins chickens, remarkably good, took the first prize, I believe, in the "Any other variety" class. Now, many remarked that these birds ought to have been disqualified, because there was a class for "Cochin chickens."

There was at Falmouth, and there is at most shows, a regulation directing that "wrongly entered" fowls will be disqualified.

As there were other highly commended pens, I do not say that but for this award I should have taken a prize; my position might have been just the same, only I think the point ought to be settled.—Y. B. A. Z.

[As there was a class for "Spanish without any limitation of colour," we think, if strictly followed, the "White Spanish" ought to have been in that class, but we do not think that in practice such strictness is ever admitted. When Spanish fowls are spoken of, everyone understands that the normal Black Spanish are meant. White Spanish and Andalusians are varieties of the same breed, and properly admitted to the "variety class." To prevent any misapprehension, Committees would do wisely to specify in their prize lists the class as being for "Black Spanish."—EDS.]

THIS SEASON'S HATCHING.

When hatched.		No. set.	No. hatched.
March 2nd.	Brahma	11	8
" 16th	White Cochins	11	5
April 6th	Brahma and White Cochins	13	12
" 14th	Brahma and White Cochins	13	9
" 24th	Brahma	13	12
" 27th	Brahma and White Cochins	15	13
" 27th	Brahma and White Cochins	15	12
May 4th	Brahma	13	12
" 8th	Brahma and White Cochins	15	13
" 8th	Black Hamburg	13	11

The Black Hamburg eggs were bought, but all the others were from my own hens, which had their nests on the ground, with a good turf underneath. The chickens were all fine, healthy birds, and have done remarkably well. I have lost two of them by cramp among the first hatchings, and one in another

by accident. They have a good run in a farmyard, and I feed them on rice, barley, crushed oats, millet, and boiled potatoes.—W. BIRCH, *Barnack*.

BEDLINGTON POULTRY SHOW.

THE fourth annual Show of the Bedlington Society was held on the 2nd and 3rd inst., in a large marquee erected in a field belonging to the Secretary, Mr. Robert Swann, and met with much encouragement and support from the gentry and agriculturists in the district. The quality of the birds shown was of a very superior kind, and some really fine ornithological specimens were exhibited. James Dixon, Esq., of Bradford, officiated as Judge of poultry, and declared the thirty-five pens of *Game* contained some of the finest fowls he had seen. The *Brahmas* were also well represented; Mr. Shorthose, of Hartford, showing three pens of birds which were very perfect in breed, though somewhat too young to compete with others of greater maturity. The prize pair in the *Cochin-China* class were fine birds, especially the cock, which excited much admiration and attention. The presence of a pair of Buff Poles in the Show—the first ever exhibited in the North of England, was noticed with much gratification and curiosity by the bird fanciers.

The show of *Pigeons* was an indifferent one, and not so good as last year's, when the prizes offered for competition were considerably less. Mr. J. Shorthose, of Hartford Bridge, and Mr. Robinson, of Sunderland, judged the Pigeons.

There were only five hatches of *Rabbits*, but these contained noble animals, and were an attractive feature in the Show.

The arrangements were most complete, and reflected credit on the Managing Committee, and Mr. R. Swann, the Secretary. The miners in the district take much interest in breeding the finer specimens of poultry, and it was pleasant to see them take such a high position in the Show. The following is the prize list:—

GAME (Any variety).—Cock.—First, J. Achinglass, Barrington Colliery. Second, J. Brough, Carlisle. Third, M. Mervot, Bebside. Highly Commended, W. Ramsay, West Cramlington (Black Red); R. Sharpe, Bebside. **GAME (Black-breasted and other Reds).**—First, J. Mason, Worcester. Second, J. Brough. Third, G. Armstrong, Netherton. Highly Commended, H. M. Jullian, Hull; E. Rutherford, Bedlington Colliery. Commended, E. Sharpe.

GAME (Duckwings and other Greys).—First, J. Mason. Second, J. Brough. Third, H. M. Jullian. Highly Commended, J. Jones, Bebside; Rev. J. G. Milner, Bellerby, Yorkshire.

GAME (Any other variety).—First, J. Brough (Lemon Piles). Second, T. Davison, Netherton (White). Third, W. Drysdale, New Delaval (Piles). **DORKINGS.**—First, H. Pickles, jun., Earby. Second, J. Shorthose, Hartford Bridge Cottage. Third, Mrs. Seamons, Aylesbury. Highly Commended, T. Bell, Cramlington.

COCHIN-CHINA.—First, W. A. Taylor, Manchester. Second, J. Shorthose. Third, T. Fenwick, Netherton. Commended, R. Hine, Bedlington. **BRAHMA FOOTRAS.**—First, E. Leech, Rochdale. Second, J. Shorthose. Third, J. Anderson, Seghill. Highly Commended, J. Scott, Netherton; W. Swann, Whinney Hill, Choppington. Commended, J. Shorthose.

SPANISH.—First, T. J. Harrison, Singleton Park. Second, J. Stalker, West Sleekburn. Third, Messrs. Bowman & Fearon, Whitehaven.

POLISH (Any variety).—First, Mrs. E. Proctor, Hull. Second, S. S. Mossop, Long Sutton (Buff). Third, R. Parsons, Sleekburn Cottage (White-crested). Commended, G. F. Allan, Sunderland (White-crested).

HAMBURGS (Golden-spangled).—First, W. A. Taylor, Manchester. Second, H. Pickles, jun. Third, R. Swann, Morpeth. Highly Commended, G. Johnson, Barrington Colliery. Commended, W. Whitfield, Hetton-le-Hole; H. Pickles, jun.

HAMBURGS (Silver-spangled).—First and Third, H. Pickles, jun. Second, W. Hall, West Sleekburn. Commended, J. Howe, Cowpen; C. Armstrong.

HAMBURGS (Gold-pencilled).—First and Second, H. Pickles, jun. Third, Messrs. Bowman & Fearon.

HAMBURGS (Silver-pencilled).—First and Second, H. Pickles, jun. Third, R. Huntley, Glebe Farm, Bedlington. Commended, W. Whitfield.

BAIRDOR FOWLS.—First, W. Swann. Second, T. Roddam, Hetton-le-Hole. Third, Miss Robinson, Stannington East Farm.

GUINEA FOWLS.—First, J. Swann. Second, T. C. Harrison, Hull. Third, Miss Robinson.

ANY OTHER DISTINCT VARIETY NOT PREVIOUSLY MENTIONED, EXCEPT BANTAMS.—First, R. Draper, Seaham (Malays). Second, Rev. J. G. Milner, Bellerby, Yorkshire (Houdan). Third, G. M. Evers, Seaton Sluice.

GAME BANTAMS (Black-breasted and other Reds).—First, J. L. Robinson. Second and Third, J. Douglass, New Delaval. Highly Commended, E. Powell, Knutsborough; T. Clark, Sunderland; P. E. Scofield, Morpeth; Messrs. Bowman & Fearon; W. Hodgson, Darlington; J. Harvey, Jedburgh.

GAME BANTAMS (Any other variety).—First, W. Dixon, Sunderland (Duckwings). Second, T. C. Harrison, Hull. Third, H. Sharp (Duckwings).

BANTAMS (Any other variety except Game).—First, J. R. Robinson, Sunderland (Black Rose-comb). Second, W. A. Taylor, Manchester. Third, T. C. Harrison. Highly Commended, Akroyd & Scott, Sunderland (Silver-laced Sebrights). Commended, W. Dixon (Black Rose-comb); J. Robson, Bebside.

DUCKS (Aylesbury).—First and Second, Mrs. Seamons. Third, J. Swann, Bedlington.

DUCKS (Rouen).—First, E. Leech, Rochdale. Second, Rev. J. G. Milner, Bellerby, Yorkshire. Third, Mrs. Brown, Bebside Farm.

DUCKS (Any other variety).—Second, J. Fairless, Wideopen (Buenos Ayres).

COTTAGERS (Any variety).—First, J. Aisbitt, Bedlington Colliery (Black Red Game). Second, J. Stalker, West Sleekburn (Spanish). Third, E. Rutherford, Bedlington Colliery (Black Red Game).

SELLING CLASS.—First, G. Taylor, Bedlington Colliery (Duckwing

Game). Second, J. Achinglass, Barrington Colliery (Golden-spangled Hamburgs). Third, P. Wilkinson, Bedlington (Game). **TURKEYS.**—First, E. Leech. Second, Miss Robson, Dinington.

PIGEONS.

CARRIERS.—First, John Thompson, Wideopen, near Newcastle. Second, H. Yardley, Birmingham. **TRUMPERS (Almond).**—First, John Thompson. Second, H. Simpson, North Seaton.

TRUMPERS (Any variety).—First, Jesse Thompson, Bingley (Yellow Mottled). Second, H. Yardley. Highly Commended, John Thompson.

CHOPPERS.—First, H. Yardley. Second, John Thompson.

TURBITS.—First, J. Clark, Thirsk. Second and Highly Commended, Jesse Thompson.

OWLS.—First, J. Clark, Thirsk (White African). Second, H. Simpson.

JACOBS.—First, R. S. Bell, Hull. Second, J. Girdley, East Hartford.

FAN-TAILS.—First, H. Yardley. Second, J. Girdley.

ANY OTHER VARIETY NOT PREVIOUSLY MENTIONED.—First, H. Yardley. Second, Jesse Thompson. Highly Commended, W. Whitfield, Hetton-le-Hole (Trumpeters); H. Yardley.

SELLING CLASS.—First, Jesse Thompson. Second, T. W. Crozier, Hirst, Woodhorn (Jacobsins).

RABBITS.

LONG-EARED.—First, W. Neal, York. Second, T. Gordon, North Seaton.

ANY OTHER VARIETY.—First, W. Neal. Second, A. H. Easton, Hull (Silver Grey).

THE SHEFFIELD ORIGINAL FANCY RABBIT SOCIETY'S SHOW.

THE half-yearly Show was held on June 1st and 2nd at the Inkerman Tavern, Alma Street. The Show was larger and better than any of the previous ones. A valuable collection of Canaries exhibited by Messrs. W. Mauley, W. Smith, W. Martin, and J. Leigh, considerably added to its attraction. The following Rabbits took prizes in their respective classes:—

LENGTH OF EARS.—First, — Allison, grey buck. Length of ears, 23 inches; width, 5½ inches. Age, 8 months 3 days. Second, — Mangham, grey doe. Length of ears, 21½ inches; width, 5 inches. Age, 4 months 3 days. Third, — Carr, smut doe. Length of ears, 21 inches; width, 5 inches. Age, 5 months 3 days.

BLACK AND WHITE.—First, — Allison, doe. Length of ears, 21½ inches; width, 5½ inches. Weight, 6 lbs. 7 ozs. Age, 5 months 29 days. Second, — Nicholson, doe. Length of ears, 20 inches; width, 4½ inches. Weight, 7 lbs. 7 ozs. Age, 4 months 23 days.

BLUE AND WHITE.—First, — Allison, buck. Length of ears, 20½ inches; width, 4½ inches. Weight, 4 lbs. 7 ozs. Age, 2 months 24 days. Second, — Frith, buck. Length of ears, 20½ inches; width, 4½ inches. Weight, 5 lbs. 5 ozs. Age, 2 months 26 days.

GREY AND WHITE.—First, — Lindley, doe. Length of ears, 21½ inches; width, 5 inches. Weight, 7 lbs. 4 ozs. Age, 7 months 5 days. Second, — Falkner, doe. Length of ears, 20½ inches; width, 4½ inches. Weight, 5 lbs. 7 ozs. Age, 4 months 3 days.

YELLOW AND WHITE.—First, — Leigh, doe. Length of ears, 20½ inches; width, 4½ inches. Weight, 5 lbs. 10 ozs. Age, 4 months 9 days. Second, — Leigh, buck. Length of ears, 20½ inches; width, 4½ inches. Weight, 5 lbs. 3 ozs. Age, 4 months 23 days.

TORTOISESHELL.—First, — Mangham, buck. Length of ears, 22 inches; width, 4½ inches. Weight, 6 lbs. Age, 4 months 9 days. Second, — Nicholson, doe. Length of ears, 20½ inches; width, 5 inches. Weight, 7 lbs. Age, 4 months 23 days.

SELF-COLOUR.—First, — Lindley, yellow buck. Length of ears, 21½ inches; width, 5½ inches. Weight, 7 lbs. 4 ozs. Age, 7 months 5 days. Second, — Mangham, yellow doe. Length of ears, 21½ inches; width, 4½ inches. Weight, 6 lbs. 5 ozs. Age, 4 months 3 days.

WRENT.—First, — Moore, brown and white buck. Weight, 7 lbs. 6 ozs. Age, 7 months 5 days. Second, — Carr, smut doe. Weight, 7 lbs. 2 ozs. Age, 5 months 3 days.

—GEORGE LINDLEY, *Hon. Sec.*

BREEDING NORWICH CANARIES.

IN reply to your correspondent "T. C. C.," my own practice is that detailed in "The Guide." When my young birds are able to shift for themselves I transfer them to a large flight cage. I usually allow them to remain in an intermediate cage with the cock during the time the hen is sitting on her next nest, and then keep them by themselves until another lot of young ones is ready to displace them, when they are removed to the flight, being by this time fully able to attend to their own wants.

While in the intermediate cage I give the birds now and then a little soft food, gradually decreasing the supply, and when they take up their abode in the flight they receive nothing but hard seed and green food. Here they remain till they show signs of moulting. Being, however, of a rather pugnacious disposition, quite at variance with the ideas of their amiable character which we learned in the nursery rhymes of our youth, they do not always agree, but "fall out, and chide, and fight," and like children of larger growth, are very apt in their quarrels to tear the clothes from each other's backs in a most unfeeling manner. One or more birds are sure to come off losers in these squabbles, and as soon as any one of them begins to assume a ragged appearance, each of his companions will take a pleasure in assisting him down-hill, seldom passing

him without giving him a kick in the shape of a pluck at his feathers, which, as often as they are replaced by a rapid and more handsome growth, continue to fall victims to the depraved appetites of his persecutors. An hour or two is amply sufficient to lay bare the back of a bird, if the attacking party make good use of their time, which, rely on it, they will do. When you notice a bird moving along the perch in a quiet, easy, off-hand sort of way, making for a place next to some unsuspecting, plump, well-feathered individual, who, possibly, has taken up his quarters next the wall to protect at least one side, be sure that gentleman has an eye to business of a fraudulent kind, and the way in which he will help himself to a few feathers from his neighbour's coat is the perfection of cool impudence. The quill end of these he will nibble with infinite satisfaction, and if they be young and contain a little blood, so much the better, and the more delicious they will be. There is generally a ringleader in these games, and the best plan is to remove him, and such as appear likely to become victims to his bad example, to separate cages, when the remaining birds will most likely conduct themselves decently.

I think that birds moult better, and on the whole do better in all respects (especially show birds), when confined separately, though Mr. Walter, of Winchester, one of our most noted exhibitors, who always brings his birds out in the bloom of high condition, assures me that he moults a number, say twenty, together. I do this myself with ordinary birds, but those which show promise of becoming stars of greater or less magnitude, I prefer to separate. My young birds all receive the same treatment as regards food, &c., whether intended for exhibition or not—indeed, I do not see how you can well determine what are fit for show and what are not till they are moulted, since some apparently promising birds disappoint one, while others of less pretentious appearance turn out gems of the first water.

We labour under great disadvantages here in the north in our large manufacturing towns as regards moulting Canaries. Iron works, spelter works, gas works, chemical works, glass works, and bottle cones, with huge chimneys continually pouring out dense volumes of smoke, are not in a general way very conducive to a clear atmosphere; and while our southern friends can keep their birds an entire season almost as clean as when fresh moulted, ours in an incredibly short season become like little sweeps. To guard against this we are obliged to have recourse to various expedients to keep them clean, covering them up with sheets and other appliances, in spite of which they will get dirty. A friend of mine uses cages with glass fronts and small ventilators, but the everlasting smoke creeps in through the smallest crevice and tarnishes the gilding of our gems.

One thing is essential as a means of inducing a high colour, and that is keeping the birds from the light. As soon as they begin to strike out new feathers cover them up immediately. If they are in separate cages cover the front with brown paper, leaving only sufficient light at the bottom to admit of the birds seeing their seed and water, or darken the window. Under any circumstances exclude the light, cover up from dust and smoke, feed high, and you may expect good results.

There are not many men, except a few of the Norwich and Derby schools, who can bring out a Norwich bird in his glory. I have conversed with many on the subject, and find that opinions as to mode of treatment differ widely. Some prescribe one thing and some another; but the above treatment and a skilful application of soap and water will bring a bird out fit to meet all comers, provided only that the quality is there to begin with. I should recommend beginners to try Crested Norwich. In the first place they are very beautiful birds, are rapidly rising to a very high place in public estimation, and the chances of obtaining prizes with them are much greater than with clear birds, since the points requisite to constitute a first-class bird are distributed over a larger area. It is true that the classes for these birds have hitherto been somewhat circumscribed at many of our great shows, but I see no reason why that should not be remedied.—W. A. BLAESTON.

STRONG VERSUS WEAK SWARMS.

I HAVE read with considerable interest the paper under the above heading in page 415, and shall be glad to learn how it is that Mr. Mitchell, of Abington, manages to obtain glasses of honey of 70 or 80 lbs. weight without bee bread or larvae. I find in my own practice that it is difficult to obtain supers of

6 or 8 lbs. without brood and bee bread; and any information which would enable me to come at all near Mr. Mitchell's results would be gladly received.

Of the advantages of strong swarms over weak ones I have long been convinced, and generally (in the case of second swarms universally), I pin two and sometimes three together in the manner advised by Mr. Taylor in the various editions of his "Bee-keeper's Manual" (page 193 of the last edition). This plan applies to the common cottage hive. With improved systems I have had little or no experience, except with Nutt's collateral hives, but I could not prevent swarming, nor brood in the side boxes, and gave up the plan. I shall be exceedingly glad to be taught a system which will prevent swarming, and give me 60 or 80 lbs. of pure honey from each hive.

I learned from a neighbour how great are the advantages of strong swarms. He said he knew a man who kept bees, and who had two hives which swarmed at the same time in May, and united. Chancing to have a very large hive, he shook them into it, and the season being a remarkably fine one, the bees filled the hive in eight days to such an extent that the new combs were not able to sustain the weight of the honey, and broke down, and he had to drive the bees into a new hive; but in those eight days they had gathered such a store that he obtained 60 lbs. of clear honey from the hive besides what was wasted by the breaking down of the combs. This seems to be a marvellous story, but I have no other reason to doubt the truth of my informant.

I think the advantages of strong swarms are self-evident. Suppose it requires five thousand bees to keep up the temperature of a hive to the point necessary to secure the health, and progress of the brood in the combs, and that the swarm is a second or third swarm consisting, say, of seven thousand bees, there are then, according to supposition, only two thousand to carry on the work of the hive; but suppose we add another swarm of six thousand to this hive, there will then be the five thousand to keep up the temperature and carry on the internal work of the hive, and eight thousand for outdoor labour, or four times as many workers in one case than there are in the other.—T. G.

RAISING QUEENS.

IN forming the nuclei to raise queens, given in THE JOURNAL OF HORTICULTURE of April, 1867, it is said, "All this must not, however, be left to chance." I have twice failed this spring, the bees would not start royal cells. In that case what am I to do with the nucleus? Are the spare combs to be empty ones or full, that are placed on either side?—J. R. F.

[The passage which you quote refers to the number of bees remaining in the nucleus, which if insufficient should be recruited in the manner described afterwards. When the brood comb is well covered with bees, they scarcely ever fail sooner or later to start royal cells. Should they, however, neglect doing so until the whole of the brood in the comb is sealed over, it should first have all the bees brushed off it, and then be exchanged for another comb containing brood in all stages, which with the adhering bees should be put in its place, and on this queen cells are pretty sure to appear. In certain rare cases the expected production of royal cells may be frustrated by the presence of fertile workers, whose existence is evidenced by the appearance of new-laid eggs in the cells. The presence of these abnormal creatures throws so many difficulties in the way of queen-rearing, that when once their existence is ascertained it is better to start another nucleus rather than lose time in persevering.]

The spare combs are better if either wholly or partially filled with honey. When they are empty, feeding often becomes necessary to save the embryo colony from starvation.]

SILKWORM-REARING IN ENGLAND.—No. 11.

Third Period and Sleep.—At the completion of this period the worms will occupy about 80 feet of space on the stages. From 90 to 100 lbs. of leaves, not somewhat larger than during the two previous periods, will be required. The worms having been transferred to their fresh papers, or calico if the latter be used, are again fed every five hours. The wooden trays will now begin to be required for transporting the papers of worms from one stage to another, as also the steps or ladders to reach the upper stages.

The consumption of leaves on the first and second days will be about 30 lbs.; on the third and fourth, 40 lbs.; on the fifth, sixth, and seventh, 30 lbs. On the fifth day the removal to fresh papers, and the clearance of the dirt, refuse, &c., must be attended to. To facilitate this work the finer nets may be used; they can be laid over the worms and the leaves supplied by their help. When the worms have all passed through the meshes of the nets to the leaves, the nets can be raised and secured to the stage above by means of small hooks, while the space below is cleaned and arranged with fresh papers, after which the worms are lowered, or some can be transported on the trays to fresh compartments if necessary.

Maintain the temperature at 70°, and keep the air of the room pure by ventilation. Fresh air is life to silkworms, and it cannot be shut out entirely from them without injury. The ventilators should be opened more or less according as the external temperature admits. Sometimes the door may be opened, and in fine, warm, calm days the windows as well. In damp weather, a flame produced by burning straw, shavings, &c., on the hearth will be beneficial, by promoting a change or movement of air in the rearing room.

It is not imperative to use the nets now, or, indeed, at all for the quantity of worms of which I am speaking, but the advantages arising from their use become more manifest in larger rearings. Many persons use no nets until the worms are near the fourth sleep.

Fourth Period and Sleep.—At the end of this period 200 feet of space, more or less, are required, and from 200 to 250 lbs. of leaves, which do not require to be cut before being given to the worms. The day after the third sleep the change of papers and removal of excrements, refuse, &c., must take place as before. This must never be neglected, for the accumulation of a bed of dirt under the insects is most prejudicial. This period lasting seven days, it will be advantageous to perform this operation three times. The consumption of leaves during the first and second days will be about 50 lbs.; on the third and fourth days 100 lbs.; on the fifth, sixth, and seventh days it again decreases to 50 lbs.

During this period gathering the leaves, feeding the worms, and cleaning them will occupy the entire time of two women. It would be well to have the assistance of two extra ones to give the worms their last meal at night, or first one in the morning. Attend to the temperature and the ventilation by opening the ventilators more or less. If the weather is sufficiently fine during the day, open the door and windows. The fourth sleep lasts somewhat longer than the preceding ones, and it is also the most difficult. While it lasts the temperature should not be allowed to fall below 70°, night or day.

Fifth Period, and last before spinning.—This is the most difficult period, for the rearer has to contend against a large amount of watery vapour every day transpired by the insects and evaporated from the leaves, likewise the putrid emanations from the excrements, which much increase. The thermometer and odour in the room must serve to indicate when more ventilation is needed. At the completion of this fifth period, occupying about ten days, from 450 to 500 feet of space will be necessary on all the stages, excepting the top one of each castle, and altogether from 1500 to 1600 lbs. of uncut leaves to be distributed in abundant meals, almost covering the worms from sight, every five hours. The day after the fourth sleep clear away the excrements and provide fresh space, repeating the same care every three days at least. In this period the worms eat voraciously, grow fast, and, of course, their excrements increase in proportion; therefore, do not neglect cleanliness and ventilation. During the first two days about 100 lbs. of leaves are necessary, during the following two, 250; in the next two, 400; in the next, 400; and in the last two something under 200 lbs. When the worms consume their meal within an hour and a half, a fresh one should be given, or what I will term an intermediate meal. This is also necessary during any of the preceding periods.

During the whole time the ventilators should be continually open, or partially so, and fire heat must maintain the temperature at as near 70° as possible. It is never necessary to exceed this degree, nor is it advisable to let it fall below 60°. Sometimes from variations of temperature or other causes, this period is prolonged one, two, or more days, as in the case of the preceding periods, but the maturity of the worms is very evident, for many may be seen crawling over the leaves without eating, as though seeking for some retreat, and many will be directing themselves to the edges of the tables or stages. They appear transparent when looked at

against the light; silk is seen issuing from their mouths over the leaves; the rings round their bodies contract, the skin about their heads becomes crisp, and they evacuate soft greenish matter.—LEONARD HARMAN, JUN.

OUR LETTER BOX.

HASTENING MOULTING (W. H. R.).—Hempseed will precipitate the operation of moulting by destroying all life in the old plumage. Canary seed will cause the feathers to fall off. That, however, which causes the loss of the old feathers is sometimes anything but favourable to the new. The heat of the hempseed and the relaxing properties of the canary do not favour growth. This is one of those cases in which we believe Nature unassisted will do well; but endeavours to forestall or to retard her operations end in failure.

MOISTENING EGGS WHILE HATCHING (St. Edmunds).—The water used for moistening eggs may be cold. The process is a base imitation of Nature. The hen of any sort leaves her eggs in the morning while the grass drips with dew; she remains searching for her food till her breast feathers are quite saturated with the cold dew water. She does not even shake herself, but sits down on her eggs. We believe that in five out of six cases the failure of eggs is from the neglect of dampings.

GEESSE SUFFERING FROM WEAKNESS (Idem).—Your Geese are suffering from weakness caused by insufficient or improper feeding, or from being shut up in a floored house at night. If they are shut up in a place where there is stone, brick, or wooden flooring, goslings would suffer as you say yours do. Feed on oats, oatmeal, bran, and gravel, mixed in a trough with water, and let them roost where they stand on bare earth.

PIGEONS NOT SITTING (Idem).—Mate your Pigeons afresh, dividing the pair that neglects its important duty.

FOOD REQUIRED BY FOWLS (T. T.).—We are unable to answer your question properly. To enable us to do so, you should describe the run and the accidental food the birds obtain. At this time of year, when the earth teems with vegetation, there are many things fowls find that are better for them than corn. Where thrashing is going on, or where many horses are kept, and the birds have access to the yard, they find helps that should diminish the consumption of corn. If your fowls have nothing but that which is given to them, and you give them nothing but corn, each fowl must have two "grasp" handfuls daily. We, however, repeat that which we have often said, you must be guided by circumstances.

HULL POULTRY SHOW.—The first prize for Coloured Dorkings at this Show was awarded to Mr. John White, of Warlaby, and not to Mr. Robson, of Louth.

THE BLACK-BREADED RED COCK, first at Birmingham in 1867, mentioned by "NEWMARKET" on May 21st, is not of Sir St. G. Gore's strain. The bird was only his property, and is now in my possession.—WILLIAM H. WHEELER, Carlton, near Nottingham.

INSECTS IN POULTRY HOUSE (Subscriber, Faversham).—They are one of the Acari or mites. Limewash the interior of the house, adding half a pound of flowers of sulphur to a bucketful of the limewash.

PADJAN FOWLS (J. E.).—The following is their description as given in the "Poultry Keeper's Manual." Size and shape of medium Dorkings; legs short and white; cock's hackle and saddle feathers bright orange; back and wings dark red; breast chestnut, green iridescence on wings; tail a rich greenish black; comb single. Hen's breast chestnut or fawn-coloured; hackle golden, edged with brown; back and wings brown in shades, each feather marked like those of the Partridge. Excellent layers and sitters; good table birds; eggs average size; shell dark cream-coloured.

FOWLS EATING FEATHERS (L. P. E.).—Where fowls take to eating feathers, or picking each other's flesh, it is a sure sign they are in a very pampered or diseased state. Purge them well with castor oil, a table-spoonful at a time; give them lettuce to eat; feed sparingly, and let the food be ground only. Let them have dust in their house, and rub the spots bare of feathers with compound sulphur ointment. They should have no food by them at any time, and be sparingly served at each meal. They do not eat each other or their feathers because they are hungry, but because they are suffering from a vitiated appetite.

REMOVING A HIVE TO A BEE HOUSE (Chatham).—We should transfer the hive from its bracket to some kind of moveable support, and then shift it little by little very gradually, until it reaches the bee house about 20 yards off.

PRESERVING PEAS (E. A. S.).—They may be preserved until the next spring if some of the summer crop are treated as follows:—"Pick them when full grown, shell them, dry them gently but thoroughly, and then store them in canvas bags in a dry place. When required for use soak them in water for a few hours until plumped up, and then boil them." The following mode has been reported to us by a person well qualified to judge of such matters as being very successful:—"Carefully shell the Peas, then put them in tin canisters, not too large ones; put in a small piece of alum, about the size of a horsebean, to a pint of Peas. When the canister is full of Peas fill up the interstices with water, and solder on the lid perfectly air-tight, and boil the canister for about twenty minutes; then remove them to a cool place, and they will be found in January but little inferior to fresh, newly-gathered Peas. Bottling is not so good—at least, we have not found it so; the air gets in, the liquid turns sour, and the Peas acquire a bad taste."

POULTRY MARKET.—JUNE 10.

THERE are indications of a better supply, and trade has somewhat improved.

From observations taken near London during the last forty-one years, the average day temperature of the week is 72.8°; and its night temperature 49.4°. The greatest heat was 93°, on the 19th and 22nd, 1846; and the lowest cold 33°, on the 20th, 1865. The greatest fall of rain was 0.84 inch.

SUGGESTIONS AS TO THE CAUSES AND PREVENTION OF LICHENS ON FRUIT TREES.

SOME time ago a correspondent called attention to what threatened to prove a serious evil both to fruit and forest trees—namely, their becoming covered with a lichen of a light grey colour. This, he stated, had been much on the increase of late years, and fears were entertained that the growth of young trees would be completely arrested, and that premature old age would set in; he asked what could be done to check the mischief, and whether its increase had been noticed in other localities as well as that he wrote from. These and similar questions are fitting subjects for inquiry in the pages of this Journal, and as the evil exists to a serious extent here (Kent), I venture to make some remarks on the causes which appear to favour the growth of lichen, and to offer a few conjectures as to its prevention.

The evil is not a new one, for moss-grown trees have probably existed ever since trees arrived at an advanced age; but it is quite possible that many trees now become covered with moss at an earlier age than in former years, and that they are much affected by it in localities where at one time it was comparatively rare. It is certain that the moss interferes with the healthy action, and checks the due development of the plant supporting it, while it no doubt hastens the death of the more aged specimen; still its growth and progress seem to be dependant on causes difficult to comprehend, as trees occupying widely different positions are often alike affected, so that some other cause than locality must be sought for.

Happening to be travelling in the western part of Lancashire lately, I had an opportunity of looking over some orchards of Apple and other trees at different places, and although the climate is proverbially moist, and few fields or enclosures were without water in a ditch, stream, or pond, the trees were comparatively free from moss or lichen; while at a very short distance from the place whence I write trees of the same description are covered with it, although water could only be obtained by digging down 100 feet or more, and, the situation being elevated, the air may also be said to be dry. Now, here is a strong argument against moisture being the cause; but I feel convinced as regards the Lancashire trees that, besides its presence, another cause kept the parasite at bay, and I believe that the strong sea breeze had much to do with its absence. In the case of the correspondent referred to, I am inclined to believe that the want of moisture, or at least of a sufficient quantity of it, caused his trees to be so overgrown with lichen, and one of the most likely theories would seem to be that the soil and climate (for both may be in fault), were not favourable to the Apple growing with sufficient vigour to resist the attacks of this parasite; or, shall we say that the climate and other things favoured its growth more than that of the stock which supported it? One or other of these causes must have been at work; but let us examine the matter still further, and

take a third place into consideration, and this is one where the lichen was also absent, and in a position where the tree was in anything rather than a healthy condition, but it may, perhaps, give us some insight into the causes which encourage the production of lichen and moss on trees.

Having an opportunity of looking at the condition of some Apple and other fruit trees, as well as of forest trees and shrubs growing in the suburbs of a large manufacturing city, I failed to discover a particle of moss, although the trees and shrubs could not be called healthy, and, in fact, were encrusted in soot as thick, probably, as the bark that covered them. Here the case was plain enough, the tree could drag on an existence in spite of the soot, but the moss could not, the impurities of the atmosphere were fatal to it; hence its non-appearance. I will not say that its dirty substitute is not the worse evil of the two.

Let us now examine the causes which contribute to the production of lichen, and on considering the three cases which I have given it would appear that a clear pure atmosphere free from saline or smoky matters tends to encourage it, and I am inclined to think that both an excess and deficiency of moisture are also favourable to it. I am not in a position to affirm this with certainty as regards living objects, but as to those which are not so, I will observe that the park here is surrounded by a close oak paling about 6 feet high. The palings being left and standing upright last a great many years, and I have often pointed them out to painters as a proof that their so-called preservative mixtures failed to keep any description of outside timber work so long as these slender strips which had no such covering. The Silver Moss, as it is commonly called, has more or less covered these palings just as it did the branches of Apple and other trees, and on a portion of the fence which passes through some damp clayey ground overhung by trees, the moss exists in greater abundance than where the fence is on high or open ground. This may be easily accounted for. A stagnant atmosphere, whether moist or dry, is in general favourable to the growth of lichens, but more so when the air is moist; and this leads me to think that the moss is as much indebted to the atmosphere for an existence as to the body it is growing on, as in the case of the oak palings, which in some instances are densely covered with a thick beard $1\frac{1}{2}$ inch long, the support it can receive from the wood must be very small; for although the moss probably to some extent hastens the decay of the oak, this lasts so many years as to prove that the amount of its substance which it has given to vegetation must have been very small. Possibly the destruction of the wood may have been counterbalanced in some degree by the preservative effect which a clayey soil is said to have on Oak timber. Posts of it fixed in the ground are said to stand longer in a clayey soil than in a dry sandy or gravelly one. As palings densely covered with this lichen will last a great many years, I imagine that the lichen is as much indebted to the atmosphere for its existence as to the wood on which it is growing, and that its presence on Apple trees is, after all, not so detrimental as might be supposed. We ought not, however, to be satisfied with this solution, as there can hardly be a doubt that a healthy tree, without

lichen is better than one with it, for although it may not take more food from the growing tree than it does from the inert oak post or paling, it must take some, and where the trees are growing on a high and dry situation, and the atmosphere affords the lichen less food, it most likely supplies the deficiency from the juices of the tree. As a proof of this, the oak paling placed on the dry ground is in a great measure free from it, while the Apple trees there, which ought only to be in their prime, are covered to an extent which cannot be otherwise than injurious.

Assuming, therefore, that this parasite is more indebted for its existence to the atmosphere than to the material on which it is growing, let us see in what way we can account for its greater prevalence during the last few years than formerly. Here we enter the regions of conjecture, and in Kent I attribute this result to the greater amount of moisture we have had in the summer months for the last three seasons than in previous years (1863 so far is an exception); but our pasture and other crops have suffered less from drought in the last three summers than before that time, and probably the lichen has taken advantage of that, to make the formidable progress which it has done in some parts of the country. In Kent, however, I am not sure that it has increased so much as elsewhere. It has always been prevalent with us, and gives many of the orchards an unsightly appearance in winter, and a stranger would hardly suppose that such large leaves and good-sized fruit would follow in summer. The trees would, no doubt, be better without such a burden as the lichen is; but, strange to say, they thrive well under it, and trees fourteen or sixteen years old often become much infested with it, and are double the size of others lately pointed out to me in Lancashire that were free from the parasite: so much for climate. The soil in Lancashire I would account the better of the two; but along with the more rapid growth of the tree we have also that of the moss, and the prevention of the latter is one of those problems not easy to solve. A partial remedy, however, is often resorted to with considerable success, and its application is easy and inexpensive.

One of the cheapest of remedies for moulds and other low types of vegetation has been brought into use here; it is lime, the employment of which is not so general as it ought to be. Taking advantage of a mild moist morning in April, before the buds were so far swelled as to be sure of their not sustaining any injury, ladders were placed against the orchard trees, and men arrayed in garments suitable for the work scattered fresh-slaked lime amongst the twigs and branches; and this adhering to the moss in consequence of its being wet, killed or very much injured a considerable part of it, and soon afterwards it began to look brown and discoloured. Of course much of the lime falls on the ground as well as on the tree; but it will do no harm there and may do good, and the tree is much relieved of its incumbrance. It is also advisable in some cases to whitewash the bole and a portion of the branches; but if lime dustings be persevered in for a few years in succession, the moss will be kept down, and the trees have a better appearance. Some orchards, however, are so liable to moss, that it is difficult to keep it under; and where the expenditure is not certain to be returned by a commensurate increase of crop, the trees are allowed to take their chance. Many tenants of orchards spare nothing likely to improve their trees, and lime-washing and lime-dusting are commonly practised in the spring.

The remark has been generally made that moss has been more prevalent during the last few years than it used to be, trees being attacked at an earlier age, and older ones to a greater extent than was the case thirty or forty years ago. Possibly, as already suggested, three or four successive seasons may have been more than usually favourable to its growth, as we have not in these suffered from the want of water. Possibly these may be followed by a cycle of dry summers, and if we then find this lichen diminishing we may safely conclude that its greater abundance of late has been owing to the causes assigned. At the same time this affords no reason for neglecting the means of diminishing a covering which is not only injurious to the tree but unsightly, and the means pointed out is within the reach of all. Although I have mentioned it only in its application to fruit trees, there is no reason to doubt that forest trees operated on in the same way would be equally benefited.

In those districts where moss is troublesome it would be worth while to consult the returns of the rain during the past year, and if the quantity falling in the summer months has exceeded the average, the evil may be due to that cause.

A - it is well to try any means of destroying moss likely to

prove effectual, those whose fruit trees are much infected, and who may object to lime as being unpleasant to handle, may perhaps obtain good results by syringing with salt water in winter, taking care not to use it too strong, and not to apply it so freely as to injure the under crop if there is any. As an experiment I have tried this and recommend it to others, but I am not quite certain whether its utility in abating one evil is not counterbalanced by its injury to the land: while in the case of lime, which is used on scores of acres of orchards every year, its only objection is the unpleasantness of dusting it over the trees, and this is not so serious a matter if the time be judiciously chosen and the operator take his position to windward. He will, however, have to be above the branches, as the lime cannot well be thrown upwards; but a little practice will enable him to perform the work with less annoyance to himself than he expects at the beginning, and the trees will be grateful for the incumbrance removed from them.—J. ROBINSON.

THE PERFECTION OF TYPE IN STRAWBERRIES.

WHEN Mr. De Jonghe wrote his excellent article on the above subject (if I recollect right, in the columns of your contemporary, the *Gardeners' Chronicle*), I little thought that in three or four years I should be found following in the same direction.

It is now pretty generally known that for some time past I have devoted a considerable portion of my leisure hours to the cultivation of fruits, and of the Strawberry more particularly; and latterly I have devoted my time in pastures new—to the raising of seedlings, which accounts for my long silence and apparent abandonment of fragarian pursuits. My last communication to your valuable Journal was in commendation of *La Constante*, which sort appeared to me to have been unduly attacked at that time; and it was this great Strawberry, doubtless, which formed in Mr. De Jonghe's mind his *beau idéal* of perfection, when he wrote the article I have above alluded to.

It will be said by some who read this communication, "What do we want of so many kinds of Strawberry? There are Strawberries enough already to satisfy any reasonable person." This is quite true, and, doubtless, a great deal of trash may be thrown on the public in the way of seedlings, everybody thinking his own pet the best production. But what if a Strawberry as handsome or handsomer than *La Constante*, with perfection of form, colour, and flavour, and all the other requisites of fertility and hardihood can be produced so as to ripen some fortnight or so before that variety? I would fain believe, then, that I have accomplished that object: and having as far as I can judge from my point of view done so, I think it my duty not to hide my light under a bushel, but to tell my brother fragarians what I have achieved, how the matter came to pass, and what induced me to try my hand at this interesting and exciting subject.

I may say, then, that having cultivated first and last some three or four hundred varieties of the Strawberry, I am pretty well acquainted with the merits and characteristics of all the known leading sorts. Amongst many kinds which have from time to time been sent to me from various parts of the world to test, I received some five or six years ago an unnamed continental variety, which to this time has not received any further attention that I am aware of. I was struck by the beauty of the plant; but, alas! two or three years in succession the plant grew and multiplied, but only about one in a dozen plants bloomed, and that sparingly. At length I obtained one very beautiful berry, and I thought to myself, "If I could only render this sort fertile, I would not wish a finer or better Strawberry," but I got tired of planting year after year for no purpose. I accordingly sowed the seed of that same fruit in the autumn of 1865. The seedlings, about fifty in number, were picked out from the seedling bed in the next spring. In the following autumn the plants were removed to their fruiting bed, and I was both pleased and astonished to find that with only two or three exceptions all these seedlings were in due time fertile.

Four or five of them were of such merit when they fruited last year that I at once named them, and this year (having multiplied each sort as much as I possibly could), my anticipations have been more than realised. The remainder of the seedlings are still in the original bed, and, doubtless, many of them are also valuable; but the first five I dropped upon are so

excellent that it will be quite sufficient at present to describe the leading traits of these only.

No. 1 from its earliness and prolificacy I named *Early Prolific*. This variety has a bright green leaf distinctly dentated, and the plant is an excellent grower and of very elegant habit. I took forty plants from the parent, each runner having three or four plants, and all of which, large and small, bloomed so early that about one-third of the bloom was killed by the spring frosts, which with us this year have been intense and remarkably persistent, scarcely having subsided even now. These plants are now pictures of beauty, and have been giving ripe fruit from the 1st of the month. Fruit large, beautifully conical, and never gets out of shape, bright glossy crimson colour, getting a little darker when thoroughly ripe; seeds but slightly embedded; flesh pure white, with the narrowest possible margin of colour on section, firm throughout, juicy, and with a most delicate Pine flavour, which cannot fail to be appreciated by a connoisseur in Strawberries.

No. 2 I have named the *Duke of Edinburgh*. It may be observed that there is a sort of masculine and feminine character, so to speak, about the general habit of the Strawberry plant and its fruit, which leads one to name them accordingly, and this fine handsome fellow at once suggested to my mind the above name. Fruit large, and very large. I took twenty runners of this kind from the parent; for this and the following kinds happened, unfortunately, to be near a tree which robbed them of their powers, so that when I got this variety under full culture I have no doubt that the fruit will be classed as very large. Foliage bold and dark green, somewhat irregularly dentate, with long stiff leafstalks; leaves less numerous than in No. 1, and quite a contrast in colour and habit; fruit obovate, very handsome, with a perfect outline, and never departs from its normal shape, small reflected calyx, and glossy neck; in colour rather darker crimson than No. 1; seeds numerous and prominent; flesh white, but a duller white than No. 1; flavour piquant and excellent. Fruit now in full gathering, and has been ripe from the 5th inst., rapidly succeeding *Early Prolific*. Every plant, however small, is a bearer.

No. 3. I purpose to name this variety, if it turns out to my satisfaction as to size, *Madame Glode*, as a little compliment to my friend Mr. Glode, than whom there does not exist a more enthusiastic, enterprising fragarian, and whose geniality and kindness of disposition deserve a small tribute at my hands. Foliage of medium colour, with small regular serrations; plant neat and compact; fruit roundish and occasionally obovate, bright red; flesh pale red, solid, juicy, and of first-rate flavour; seeds numerous and prominent; size at present large medium, but as the plants have not had the benefit of good culture, I anticipate that the size will be ordinarily large.

No. 4 I propose to call *Sir Robert Napier*. Foliage bright green, with a yellowish tinge than No. 1; leaf firmer than that variety, and not quite so broadly serrated; fruit rather longer cone than *Early Prolific*, and occasionally slightly angular and flattened; calyx semi-reflected; seeds numerous, and decidedly prominent; flesh pinky white and sometimes pink, firm and juicy, with a piquant brisk aroma.

No. 5, *The Sultan*, in honour of His Majesty's visit to this country. Dark green foliage, and plant of similar habit to No. 2, but leafstalks shorter, and leaves not quite so dark as in that variety. Fruit large, obovate, and roundish, type as to shape not quite so perfect as in the *Duke*; colour dark crimson; seeds thickly disseminated and slightly depressed; flesh darkish red throughout, firm and juicy; flavour vinous and delicious.

The above five varieties it will be observed are totally distinct in almost every particular from each other, and none of them like the parent. They ripen in succession in the order placed, and the respective fruits are for the most part larger in the same order, save that No. 2 as an early second is larger in proportion than the rest. The two first varieties I consider so valuable as handsome additions to our early Strawberries, that I think I should not be justified in keeping them to myself. I intend, therefore, when the stock is sufficient (which cannot be before next season), to take some means of bringing them before the public; and if no other channel opens, I may, probably, give my gardener, who has necessarily taken much trouble off my hands during these long-continued operations, the privilege of so doing. As a professional man, actively engaged in various ways, it is doubtful whether I can go through the usual routine of exhibiting these seedlings, but I shall do so if time and circumstances permit; but at any rate I hope to give the Editors an opportunity of examining their merits,

as there ought to be some guarantee to those at a distance who cannot see my beds of the correctness of my descriptions. Those who see the plants growing, see them to greater advantage, and many excellent judges of fruit in this neighbourhood who have visited my gardens have been struck with the beauty and excellence of these varieties. I shall be happy to see any one who feels disposed to give me a call, either this season or next.

The *Early Prolific* is so early, so handsome as a fruit and as a plant, and so delicious in quality, that I feel sure it has no compeer in its season of excellence, if form, colour, size, and flavour combined in the same variety, are to be considered the types of perfection; whilst as to the *Duke* we have at once a larger, handsomer Strawberry if possible than *La Constante*, before that splendid sort growing by its side is scarcely half swollen, and certainly cannot be ripe in any quantity for some fortnight or so to come.

Amongst the remaining seedlings is a handsome, large-leaved, large-fruited, variegated variety. The fruit is not sufficiently ripe to describe now, but I mention the subject because one or two notices have lately appeared in the *Gardener's Chronicle*, of a variegated variety in Devonshire. I was not aware of any such variety of bold growth and bearing large fruit being in existence. I knew there were one or two small-leaved sorts, occasionally, but not very frequently, bearing a fruit about the size of the wild Strawberry, remarkable only as curiosities; but Mr. Foote tells us in the *Gardener's Chronicle*, of May 23rd, that the Strawberry in question was found in a bed near Exeter, in July, 1866, but whether it is a sport or a seedling he is unable to say. I must say, with all due deference to the opinions of others, that I do not believe in sports as to Strawberries. Either it is a seedling or an unnoticed variety previously in existence, there is no such thing as a sport: but I quite agree with Mr. Foote, that a handsome variegated variety equal even as a bedding plant to some of our best *Pelargoniums*, must ere long attract attention, and I felt myself very fortunate (though, as Lord Dondreary says, "it's a thing that no fellow can understand"), in having raised such a Strawberry, and which I shall take another opportunity of noticing when I have saved a little stock and know more of its qualities. That the above, which I have temporarily named *Pandora*, is a genuine seedling and from a good strain I know, from the fact that I gathered and sowed the seed myself, and have witnessed already the virtues of its allied seedlings.

The foregoing and other facts within my knowledge have only strengthened my opinion, that Mr. De Jonghe's theory as to the utter uselessness of artificial fertilisation as enunciated at page 363, Vol. VIII., of *JOURNAL OF HORTICULTURE*, is perfectly sound and correct. Besides the above varieties, raised from a sort nearly barren, which I have enumerated partly to illustrate the truth of his theory, I have a similar instance in the case of the celebrated large early sort, *Marguerite*, raised by M. Lebreton. This sort, prolific enough on the continent, with me almost refuses to bloom. Year after year I have cultivated the plants under all kinds of circumstances, but nothing would induce fertility. At length, previous to entirely giving it up, I determined to sow the seed of the first fine fruit I could get. I did so, and raised sixty seedlings, the whole of which are fertile, and only one of them at all approaching to the style of the parent, and many of them are so early and so much higher flavoured than the parent—the chief desideratum, that next year I hope to be able to speak of them.

I have had delicious fruit from these seedlings without any efforts as to situation, &c., from the 29th ult. The present terribly dry, scorching weather in the midland counties is, however, very much against the runners, which I am endeavouring to classify and save for the above purpose.

If another illustration were wanted in favour of Mr. De Jonghe's theory, I have some seedlings from *La Constante*, one of which (No. 12), is very early, and of quite a distinct shape and flavour, and extremely delicious. Another No. 8, is a bold grower, with a bright green leaf like *Victoria*, but handsomer, with a firm, bright salmon red, perfectly globular fruit, which might but for its origin be justly called a much-improved *Victoria*. Here is a perfect departure from every characteristic of the parent, but the fruit is, nevertheless, in another direction, a type of perfection.

I have large quantities of other seedlings coming on, of different strains to those above mentioned, from which I expect great results; and I may here observe that all depends upon good luck in getting the right strain. With the same attention and knowledge of the subject one man may be more fortunate

in a given period than another; for unless the operator hit upon a good strain, he may sow seed of half the sorts in his collection, and have only to mourn over his continual disappointments. Stick, therefore, to a good strain, and from the same Strawberry, as I have myself witnessed, sorts may be raised as wide asunder as Black Prince is from Trollope's Victoria.

One word as to the flavour of Strawberries. This every fragararian knows varies very much with soil and situation. I speak from my own soil, and in the majority of instances Strawberries are good and keep to their characteristic flavour; occasionally, however, we observe a great departure. Sir Charles Napier and Victoria on Mr. Rivers's soil, I recollect, are so acid that the addition of sugar is absolutely necessary, whilst on my ground these sorts, the latter especially, are sweet and refreshing. Within two miles of this place, again, Victoria is so sour and different in flavour, that but for its form and colour I should scarcely recognise it. Possibly, on the other hand, by the same rule, Strawberries raised on my soil may be richer in flavour elsewhere. Form, size, and colour are not so much influenced, and these are the more unchangeable types of perfection which lend such a charm to success in raising a new Strawberry.

Of mid-season varieties there are plenty, and there is scarcely room for improvement. What we want is better early and late sorts; and if I should be as successful in raising late varieties with these attributes of perfection, as I trust I have been with early ones, I shall have done some little service to horticulture, if only in contributing to the decoration of the dessert. At any rate, these are, in my humble opinion, steps in the right direction.—WILLIAM RODEN, M.D., A.M., *The Grange, Kidderminster.*

[We have been favoured by Dr. Roden with an opportunity of examining and tasting two of his new seedlings, Early Prolific and Duke of Edinburgh, and we were greatly impressed with the wonderful advance these two varieties are on all other early kinds, both in size and flavour. The former produces its fruit literally in bunches, and is as early as Black Prince, with fruit three times the size; the latter not quite so early, but nearly so, and the fruit immensely large, one specimen we had being over 2 inches in diameter, and the flavour remarkably fine. These are most valuable and characteristic acquisitions to the already too-numerous varieties of this estimable fruit, and they must become essential in every garden.]

JUDGING AT THE ROYAL HORTICULTURAL SHOW.

"J. W." says, page 419, that Mr. Turner's and Mr. Paul's collections of Variegated Zonal Pelargoniums ought to have been disqualified, for that they did not fulfil the conditions required by the schedule. I differ from him entirely. May Queen in Mr. Turner's, and Snowdrop in Mr. Paul's collections are true Variegated Zonals. Zonal is a term used and well understood as applying to a section of Pelargoniums, and distinguishing it from the florists' large-flowered, the French, the Fancy, and other kinds of Pelargoniums, and a Zonal in this sense may, anomalous as it appears, show no trace of a zone at all.

If it were intended that gold green and red, or white green and red Zonals (tricolors or quadricolors), should alone be eligible for exhibition in the class in question, it seems to me it should have been so expressed. As the wording stands I submit that Mr. Turner and Mr. Paul had a right to exhibit the plants they showed in this class.—P.

POTTING AURICULAS.

I see that you have inserted a paragraph by Mr. Hepworth, from "The Gardener," on the best time for potting the Auricula. He says July. Now, I beg to differ, and for the very reasons that he has advanced, and say that it is better to pot them as soon as the bloom is over. They have then a better chance of making their growth and filling the pots with roots than if potted in July, when they are somewhat at rest; and lest it might be thought that they would remain too long in the pots without change of soil, and so get soured, it must be borne in mind that from November to February they hardly require any water at all, and then a good top-dressing renovates them amazingly. I used always to pot in August, but of late years have adopted this plan, which certainly answers better

down south; it is that which Mr. Turner so successfully follows, though I am aware that other successful growers treat them differently.—D., *Deal.*

AMONG THE FIRST TRACES OF OUR NORMAN FOREFATHERS.

THREE tourists met on the Grand Parade at Eastbourne during last week—fair specimens of the classes into which such travellers may be divided. The Utilitarian observed, "I never saw such healthy, abundant crops—Wheat, Hay, Apples—all splendid. We may expect a quiet winter, for plenty and peace are a cause and effect."

The Valetudinarian added, "And what splendid weather!—temperature 85° in the shade. I do hope now to be released from this fettering rheumatism."

The Lover of the Beautiful, while those comments were uttering, was rewarding a little bare-legged girl for a spray of Roses she had presented, and well they merited the reward, for they were beautiful specimens of the old Cabbage Rose, and, like all the Roses in this vicinity, intense of colour and without an insect or a blotched leaf to mar their effect by a reminder of decay. "Have you seen such Roses as these since you were boys?" asked this third of the tourists, and then added, "How they revive memories of my old home, and make me forget that I alone am left of the group once gathered there." Full sympathy was expressed in that feeling, and this comment might have been quoted, "The charm of flowers to the lonely-hearted is often more than words can tell. They are a pleasure and delight; they recall happy days, bring kind friends to mind, and soothe and please in the saddest hours."

Those tourists passed a week in close companionship, and the following are jottings of their "sayings and doings."

This present rapidly increasing resort for bathing is not the East Bourne of the olden time. That is situated a mile and a half inland, deriving its name from a bourne, or rivulet, rising on the eastern side of the Downs, terminating at Beachy Head, and which extend throughout the length of Sussex, Hampshire, and Wilts. The head-spring of this bourne issues from the chalk in a field attached to the parsonage, passes through the garden of the Manor House, and mingles with the sea at Broad-bourne. From that stream the Romans drank eighteen hundred years ago, for the mosaic pavement of the rooms and bath of a Roman villa were discovered many years since near the western end of the Grand Parade.

That Parade is formed of three broad terraces or promenades, the lowest of which is washed by the sea. They rise one above the other, and the bank sloping from the higher to that below is planted with that perverse clinger to our warm sea-board the Tamarisk (*Tamarix gallica*). Such a belt as this will form when a year or two older will be unmatched. The Tamarisk deserves the epithet of perverse because it refuses to grow except on our southern coast. This remark induced an old resident who overheard it to rejoin, "The Oak is as perverse hereabouts, for there are but two near Eastbourne, and one of them is nursed in the garden of Oak Cottage, and that would not be if the cottage did not belong to the Penderells, descendants of those who saved Charles II."

This led to the just observation that the gardening around is worthy of high commendation. The climate is friendly to exotics; flowers flourish in the open air, and that which readily rewards our labour has that care readily bestowed. The love of gardening seems to be in all classes. The areas in some of the streets are filled with flowering plants, and in their shadiest corners are rockeries tenanted by vigorous Ferns. In the windows of the cottages are Pelargoniums, Fuchsias, Calceolarias, and other flowers, looking so healthy and so intense of colour as to command notice, and the gardens around the cottages are well stocked with cleanly-cultivated vegetables and fruits.

Among the fruits must the old orchard trees be well remembered. Who can tell how old those Apple trees are, the stumps of which, alive yet, are in the garden adjoining the ruins of Hurstmonceux Castle? or of those in some of the old gardens at Waincock? It was too early in the year to identify the varieties, with but one exception, and that exception was the nearly extinct Old Codlin. Its leaves and fruit, though young, were unmistakable. It is in a cottage garden, and the old dame there resident, overhearing its praise, came forward to tell that it was strong "cause it was grafted on a Black Jack." What this stock is called in a less local vocabulary did not then

appear; but Mr. Ashwell, the proprietor of the Strawberry Gardens at Wannock, explained that the Norfolk Beech is known about Eastbourne as the "Black Jack."

Those Strawberry gardens are well worthy of a visit. They have been yielding Strawberries ever since 1792. They occupy about four acres, and as much of the beds are under fruit trees, and as many of our modern varieties are cultivated, and as there is a stream of water winding through and dividing the gardens, the supply of fruit is large and long-continued. The gardens are open to the public, and in the season forty visitors during a day visit them to banquet on Strawberries, cream, and bread and butter. Mr. Ashwell is rapidly adding to the means of fruit culture there, and visitors are treated too courteously not to be induced to repeat their visit.

It was observed during the tourists' visit that Wannock is a corrupt pronunciation of Walnut Street; that nut tree flourishes in the neighbourhood, as it does in all alluvial soils in the vicinity of the chalk formation. There are some very fine specimens near Old Eastbourne.

The streams, such as that at Wannock, and the widely-extending levels around Eastbourne are so favourable to the growth of aquatic and marine plants, that nowhere in England are they to be found more fine or in greater numbers. The beautiful *Butomus umbellatus*, or Flowering Rush; *Caltha palustris*, or Marsh Marigold, here called "Water-blob"; *Crambe maritima*, or Sea-kale, near Beachy Head; *Glaucium luteum*, or Horned Poppy, near the beach; *Nuphar lutea*, or Yellow Water Lily, and *Nymphaea alba*, or White Water Lily, in the still waters of Pevensey Level, and many other smaller aquatics were found by the tourists. On the Downs of Beachy Head and its vicinity also were noticed the *Ophrys apifera*, Bee Orchis; *Ophrys muscifera*, Fly Orchis; *Orchis ustulata*, Dark-winged Orchis; *Orchis compea*, Fragrant Gymnadenia; *Orchis pyramidalis*, Pyramidal Orchis; *Orchis mascula*, early Purple Orchis; *Orchis fusca*, Brown-winged Orchis, in the marshes; and *Orchis latifolia*, in the moist meadows near Polegate.

No place in England is more associated than is Pevensey with memorable events and personages. It was the "Anderida Portus" of the Romans. Its castle is partly of Roman, partly of Norman architecture; it was the last stronghold of Harold, and the first stronghold of the Norman William. It and the surrounding districts were granted to his Norman followers, and the names of places around mark how the Norman mastery prevailed. Langley Point is Languey, or Long Nose Point; Pevensey, Hnrtmonceux are all compounds of Anglo-Saxon and Norman names. The present race cling to the Norman French, for even the bellman of Eastbourne still prefaces his announcement with the old "Oyez, Oyez, Oyez," which some of your readers may not know is "Hear ye, Hear ye, Hear ye."

Then Pevensey was, too, the birthplace of Andrew Borde, the wandering friar and physician of Henry VIII., who punned upon his own names, and designated himself *Andreas Perforatus*, or Bored Andrew, and was through life so jocular as to have given occasion to a jester being called a Merry Andrew.

Wilmington has no other connection with Pevensey than that the tourists visited the ruins of its priory on the same day. Those ruins are trivial, but the Yew tree in its churchyard is not, for the trunk of that tree is 22 feet in circumference, and its branches overshadow a circle 80 feet in diameter. That church is on an eminence, and may serve to sustain the opinion that one of the reasons why such trees were planted near churches was that they might shelter those edifices. At all events, the last statute passed in the reign of Edward I. was entitled "*Ne Rector arbores in cimiterio prosternat*" (The Rector shall not fell the trees in the graveyard), and the preamble of the statute states that the trees planted there were to screen the church from the wind. Churches in those times, as Daines Barrington observes, were built low, and the thick, wide-spreading evergreen foliage of the Yew answered for shelter better than that of any other tree.—G.

CARBOLIC ACID.

NOTICING IN THE JOURNAL OF HORTICULTURE for May 21st, that carbolic acid will prevent Odium, &c., I placed a dish or two in a large vinery in which Odium was showing itself, and after leaving it in for three or four days, I am very much disappointed at finding that it has no effect on the Odium, and has injured the foliage of the Vines to a most disastrous extent. Can any one else give their experience on this matter?—G. R.

[We published only an extract from another journal, and that extract only says that it will "prevent," not that it will de-

stroy mildew. We shall be obliged by relative information from any of our readers. The above communication will act as a warning to be careful in trying the efficacy of the acid in question.—Eus.]

ROYAL HORTICULTURAL SOCIETY.

JUNE 16TH AND 17TH.

SPECIAL PRIZE AND PELARGONIUMS. Since this was properly one of the Society's minor shows, it attracted nearly the dimensions of a great show, and, from the diversity of the subjects which it brought together, was of a very interesting character. As regards the extent of the Show, it filled a portion of the north-eastern conservatory arcade, the conservatory itself, and the whole of the north-western arcade, in which were densely packed not only the variegated Zonal Pelargoniums. The arrangement of the tables in the conservatory was much more effective than on former occasions, there being a small octagon stage at each end, the one filled principally with specimen Orchids, the other with a charming miscellaneous group in which there were also several Orchids, contributed by Messrs. Lee, of Hammer Smith. In the centre was a stage of similar form, to those at each end and occupied with Roses, whilst between the central and end stages were two oblong ones divided up the centre. The whole had a symmetrical appearance, and only wanted something to conceal the wood-work to make it all that could be desired in the absence of a place specially adapted for holding exhibitions.

Taking now the classes in the order of the schedule, those from 1 to 7 were for special prizes offered by members of the Council, & which the Society added about half the amount as second prizes.

The Duke of Buccleuch, President of the Society, offered in Class 2 a prize for the nine best cultivated Azaleas; but as it is now getting late for fine specimens of that plant, especially after the hot weather of the last fortnight, no one came forward to claim the prize.

The same nobleman also offered a prize for the nine best cultivated Roses in pots, which was taken by Mr. William Paul with Paul's Giant, La Reine, Anna de Schleswig, Madame A. de Rougemont, Baron A. de Rothschild, Colne Forestier, Semateur Vaise, Catherine Guillot, and Lelia. These were well-grown specimens, and covered with flowers, but the latter in consequence of the heat had lost that freshness which in the earlier part of the season rendered the Roses exhibited more than usually beautiful. Mr. W. Paul also exhibited a collection in small pots, for which an extra prize was awarded, and Messrs. Paul & Son had one for boxes of cut blooms, among which we noticed a large example of the new Rose, Duke of Edinburgh, and Boule d'Neige, a fine white Hybrid Perpetual.

In Class 3, which was likewise for a prize offered by the Duke of Buccleuch, the subject being the nine best cultivated Zonal Pelargoniums in bloom, Mr. Weston, gardener to D. Martineau, Esq., Clapham Park, was first, with finely-grown plants from 3 feet to 3½ feet in diameter. These consisted of Herald of Spring and Excel-lest, scarlet, Monsieur Martin, Emily Vancher, Sparkler, Eugénie Mizard, Sensation, Amelia Grisau, and Beauté des Farterres, lilac rose Nosegay. Mr. G. Wheeler, gardener to Sir F. Goldsmid, Bart., M.P., Regent's Park, was second, but the plants were rough, and showed to a great extent the wire on which they were trained. Among them, however, were some very good kinds, as Dr. Lindley, which makes a fine pot plant, and Mrs. William Paul, with fine large flowers.

Class 4 was for a prize offered by W. Wilson Saunders, Esq., and which had for its subject the ten best cultivated Orchids. This was taken by Mr. Williams, of Holloway, who had *Epidendrum vitellinum*; *Vanda tricolor*; *Vanda saxavis*, good, though not specially remarkable; *Oncidium leopoldinum* with nine spikes of yellow and brown flowers; *Lelia purpurata* with two spikes, each with four finely-colored flowers; *Cypripedium barbatum* superbum, with twenty-eight blooms; *Acridis larpentei*, with three spikes; *Acridis odoratum majus*, a splendid plant with eleven racemes of bloom; the bright-colored *Acridis Lobbi*, and *Cypripedium superbum* with a dozen blooms.

In Class 5, the best twenty herbaceous plants in flower, Mr. Saunders likewise offered a prize, which went to Mr. Ware, of Tottenham. Among the plants which he exhibited were *Platanus atrovirens* and procumbens, the former with rich blood-red, the latter with small but pretty pink flowers; *Stictis maritima* rubra, with two heads of deep rose-colored flowers; *Orchis foliosa*, ornamental alike by its spotted leaves and neat heads of flower; *Oxalis spectabilis*, with lilac purple flowers, and leaves prettily marked with purple; *Campanula glomerata* alba; *Veronica maritima* alba, with very neat heads of white flowers; double white *Spiraea filipendula*; and *Sedum peruviana* alba. The same exhibitor also had an extra prize for cut flowers of herbaceous plants, among which were several of the above, *Lychnis chalcedonica*, Foxgloves, *Polonia*, *Isides*, and *Lilium*, and he likewise sent cut Roses and Antirrhinums.

Class 6 was for the best display of bedding plants in wooden boxes 10 inches square by 5 in. high, the prize here being also offered by Mr. Wilson Saunders, and it was awarded to Messrs. F. G. Henderson, of the Wellington Nursery, for the most and best interesting collection of these plants which we ever saw exhibited. Altogether it comprised one hundred species and varieties, consisting of Pelargoniums of various classes, Saxifrages, Echeverias, Cusceas, Centaureas and other white-leaved edging plants, variegated Grasses,

Euonymus, *Iresine Herbstii*, *Perilla*, and so many other plants that their names constituted of themselves a small catalogue which was freely distributed. The whole was surrounded by *Retinospora leptoclada*, forming very neat, small, pyramidal plants. The example which Messrs. Henderson have set will doubtless be followed by others, and in this way the public will have an opportunity of comparing and selecting for bedding and other purposes a vast number of plants the merits of which are but too little known.

The last class in which a special prize was offered was that for the best collection of Lilies in pots, the donor being G. F. Wilson, Esq. This was taken by Mr. Burley, Albert Nursery, Bayswater, who sent several pots of *Lilium auratum*, the Tiger, Martagon, common white, and Turk's Cap Lilies, an *Amaryllis*, and one or two other plants not properly Lilies, though belonging to that family. The best collection of Lilies, however, were those furnished by Mr. Wilson himself as cat spikes, to which the Floral Committee awarded a special certificate.

Of new plants there was a fine show, to which Messrs. Veitch largely contributed. They took the first prize for the best six new plants sent out in 1866 and 1867 with *Retinospora plumosa*, a very graceful species, and well deserving its name from its feather-like appearance; *Sanehezia nobilis variegata*, the yellow-veined foliage of which renders it one of the most handsome of variegated plants; *Anthurium regale*, with noble white-veined leaves; *Maranta Veitchii*, one of the finest of ornamental-foliaged plants; *Nepenthes hybrida maculata*, hung with numerous pitchers; and *Dalechampia Roeziana rosea*, with rosy bracts. Mr. Bull was second with the last-named plant; *Maranta roseo-picta*, with beautifully-marked foliage; *Encelphalartos gracilis*, *Trichinium Manglessii*, *Zamia villosa*, and *Echites rubro-venosa*, with leaves beautifully veined and reticulated with red. Mr. Williams sent *Maranta roseo-picta*, *M. Veitchii*, *Gleichenia circinata glauca*, *Fittonia argyroneura* with leaves veined with pure white, *Miconia peruviana*, with Sphaerogone-like leaves, and *Dipladenia amabilis*, with glowing deep rose-coloured flowers.

For the best six new plants sent out in 1868 Messrs. Veitch were again first with *Begonia boliviensis*, *Alocasia Jenningsii*, *Retinospora filicoides*; *Croton interruptum*, with bright red midribs to its narrow leaves; *Davallia paryala*, a charming little Fern with minutely divided leaves; and *Alocasia intermedia*, with large metallic green leaves having a silvery lustre. Mr. Bull was second with *Cibotium regale*; *Alocasia Jenningsii*; *Cyrtodeira chontalensis*, with brownish leaves with a band resembling frosted silver longitudinally along the centre; *Dicffenbachia eburnea*, with white markings; *Maranta virginalis*, banded with white; and *Panicum plicatum foliis niveo-vittatis*, with leaves $1\frac{1}{2}$ inch wide, exhibiting a few narrow white stripes, but ineffective as shown.

The best new plant shown for the first time in flower in Great Britain was *Dipladenia holiviana* from Messrs. Veitch. The flowers are very distinct in colour from those of the other *Dipladenias*, being white with a yellow throat, and measure about 2 inches in diameter. Messrs. Veitch likewise exhibited *Osbeckia virgata*, with purple flowers and prominent yellow stamens. It is a native of Ceylon. Mr. Bull was second with *Lysimachia tubinoides* with small white flowers.

For the best new ornamental-foliaged plant Messrs. Veitch were also first, exhibiting *Croton Wisemanii*, with leaves beautifully mottled and marbled with green and yellow, and a rich yellow band along the centre of the leaf. The same firm likewise sent *Alocasia Cheloni*, with magnificent bronzed leaves, especially when young, and being then remarkable for their splendid metallic lustre. For the best new garden seedling in flower, Messrs. Veitch took another first prize with a hybrid *Cattleya* raised between C. Chelsoni and C. Aeklandie, in which the colours are purple, white, and brownish green spotted with purple. Mr. Bull was second in the same class with Ivy-leaved *Pelargonium* Princess Thyra, with for its class large pale rose flowers, lined in the upper petals with crimson.

A class for six fine-foliaged and six flowering plants followed next in the schedule, and in it Mr. Williams was first, with a fine *Croton variegatum*, *Dasyliroton acrotrichum*, *Fatania borbonica*, *Yucca quadricolor*, *Pandanus ornatus*, *Draecena lineata*, a fine specimen of *Pimelea decussata*, an *Ixora*, and other flowering plants. Mr. Wilkie, Oak Lodge, Kensington, was second in the same class, having a good specimen of *Pimelea*, a balloon-trained *Rhynchospermum jasmoides*, the Cocoa Palm, Variegated Aloe-leaved *Yucca*, and other plants with ornamental foliage.

In the next class for the best twelve Stove and Greenhouse plants, Mr. Ward, gardener to F. G. Wilkins, Esq., Leyton, had a first prize for a well-grown collection, in which were good specimens of *Dipladenia crassinoda*, *Aphelexis mearnsii* purpurea, Barnes's variety of *Phenocoma prolifera*, the showy *Kalosanthes Phoenix*, and good *Heaths*, &c. Mr. Wilkie, who was second, had good *Heaths*, *Clerodendron fallax*, and other plants. Mr. Tanton, of Epsom, had a third prize for a collection in which *Allamanda Hendersoni* was conspicuous by the great size and abundance of its flowers, in addition to which he had *Heaths*, *Aphelexis*, and *Statice*.

The Subscription prizes for Variegated Zonal *Pelargoniums* excited much interest among exhibitors, and they brought a multitude of varieties, many of them very nearly approaching each other, but between which the shades of distinction were infinite.

In Class 15, for the best Golden Variegated Zonal *Pelargonium* not in commerce, Messrs. E. G. Henderson were first with Mrs. Grieve, a

splendid variety with large leaves having a broad dark crimson zone and a distinct yellow edge. Mr. Stevens, of Ealing, was second with *Achievement*, also splendid, having a crimson and nearly black zone and a narrow yellow edge. Messrs. Carter were third with *Ettie Beale*, with a bright and dark crimson zone, green centre, and regular yellow margin, a very pretty variety. Mr. Mann, of Brentwood, was fourth with *Masterpiece*, having fine large leaves very well marked. Messrs. Lee, Turner, Grieve, Tanton, F. & A. Smith, Garaway, Saltmarsh, and E. G. Henderson, also exhibited in this class, and some of their varieties were also fine.

The best Silver Variegated Zonal not in commerce, came from Messrs. Lee, of Hammersmith, and was named Mrs. John Clutton. It has large leaves with a fine white edge, and a dark zone with fiery markings. Mr. Grieve, Clifton Hall Gardens, was second with *Lass o' Gowrie*, having a broad white margin, and a rosy crimson and dark crimson zone, a finely-marked variety. Messrs. Carter were third with *Princess Beatrice*, having a broad white margin surrounding a dark crimson zone with flushes of bright crimson. Mr. Turner, of Slough, took the fourth prize with Miss F. Stevens, with a finely-marked dark zone flushed with rose.

For the best Gold and Bronze *Pelargonium* not in commerce, Messrs. F. & A. Smith took the first prize with *Criterion*, a magnificent variety, having a rich deep brownish red zone, which, as well as the golden margin and centre, is very regular. The same firm was second with *Arab*, having a broader margin and a somewhat greener ground colour, but with the zone very rich and distinct. Mr. Turner was third with Mrs. Simpson, also a handsome variety, but not so regular in outline; and Messrs. Lee were fourth with *Lady Farnham*, with a broad reddish brown zone and distinct yellow edging.

The best Golden-leaved variety not in commerce was *Golden Emperor* with large golden leaves, with a slight tinge of the palest green, and very beautiful. This came from Messrs. Downie & Co., and the second prize went to Messrs. Saltmarsh for *Golden Queen* with pale golden leaves, scarcely less beautiful. Mr. Keeler, of Lewisham, was third with a kind also called *Golden Queen*, and Messrs. F. & A. Smith fourth with *Golden Glen*.

In the next class for the best Silver-edged *Pelargonium* not in commerce, Mr. Turner was first with *May Queen*, with a fine pure white margin, and apparently of free habit of growth. The second prize went to Mr. Turner for *Bright Star*, also an excellent variety; and the third to Messrs. E. G. Henderson for *Bridal Bouquet*, with a leaf flatter than most others, and broadly edged with white.

The next class was for the best three Golden Variegated kinds not in commerce, and in this the first prize went to Messrs. Carter & Co. for *Sir R. Napier*, having a splendid blackish crimson zone and being very distinct; *Prince of Wales*, which maintains the high character which it gained as a seedling; and Mrs. Dunnett, with a fine, broad zone. Messrs. F. G. Henderson were second, and Messrs. F. & A. Smith third, with *Jetty Lacy*, very fine, *Viceroy*, and *King*. The last-mentioned firm was first in the next class, that for the best three Silver Variegated kinds, showing *Banshee*, *Peri*, and *Miss Burdett Coutts*; Mr. Turner being second with *Excellent*, *Clara*, and Mrs. F. Stevens; and Messrs. Garaway third with *Silver Pheasant*, *Julietta*, and *Cup of Beauty*.

In the class for the best three Gold and Bronze varieties not in commerce, some very fine ones were shown. The first prize was taken by Messrs. F. & A. Smith with *Goldfinder*, having a broad reddish chocolate zone; *Plutus*, darker in colour; *Sibyl*, with a broad deep-coloured zone and narrow margin, the ground colour greenish yellow. These varieties were very beautiful, bold, and effective. Messrs. Carter & Co. came second with *Black Prince*, with a broad very rich chocolate zone, *Cleopatra*, and *Anthony*, very pretty, with a broad golden edge. The third prize went to Messrs. Saltmarsh for the Hon. Mrs. Claghton, *Plutus*, and *Bronze Queen*.

The best twelve Zonal *Pelargoniums*—Variegated, Gold and Bronze, or Golden-leaved—came from Mr. Turner, and consisted of *Excellent*, *Beauty of Guestwick*, *Clara*, *Beauty of Salthill*, *Sophia Dumaresque*, Mrs. Turner, Mlle. Christine Nilsson, *Lady Cullum*, very fine, *Empress Eugenie*, *Queen Victoria*, Dr. Simpson, and *Princess of Wales*. Messrs. F. & A. Smith were second with a very evenly-grown set of plants, the kinds being *Snuray*, *Exquisite*, *Bullion*, *Banshee*, *Coronet*, *Miss Burdett Coutts*, *Lonisa Smith*, *L'Empereur*, *Enchantress*, *Plutus*, very fine, *Sultan*, and *Imperatrice Eugenie*. Messrs. Carter & Co., who were third, sent *Princess of Wales* with a beautifully coloured zone, *Goliath*, *Fairy Land*, *Aurora*, *Sultan Abdul Aziz*, *Royal Standard*, *Ruby Ring*, *Marian* with a bright crimson zone, *Josephine*, *Egyptian Queen* very effective and good, *Prince of Wales*, and *Daybreak*. Messrs. E. G. Henderson also showed *Lady Cullum*, *Italia Unita*, and several other fine varieties in this class.

Class 24 was for the best six of any class, nurserymen only exhibiting, and in this the prizes were awarded respectively to Messrs. Carter, Messrs. Downie & Co., and Mr. Turner, who each exhibited well-grown plants. In the corresponding class for amateurs, Mr. Jones, of Highgate, was first, and the second prize was withheld.

For the best six Gold or Silver Variegated Zonal varieties, the prizes went to Messrs. E. G. Henderson, Mr. W. Paul, and Messrs. Lee, of Hammersmith; and for the best six Gold and Bronze kinds, to Mr. Cannell, Messrs. Downie & Co., and Messrs. F. & A. Smith.

The best three plants of any Golden or Silver Variegated Zonal variety in commerce, in 6-inch pots, were *Howarth Ashton*, from Messrs.

M. G. Henderson, and which exhibited a fine blackish crimson zone; Messrs. Perkins, of Coventry, were second with Countess of Craven; and Mr. Turner third with Mrs. Turner.

The best six Nosegay *Pelargoniums* in pots came from Messrs. Downie & Co., and consisted of Duchess of Sutherland with splendid trusses of magenta-tinged rose-coloured flowers, Le Grand, King of the Nosegays, very fine, orange scarlet; Countess of Strathmore, Mrs. Laing, and Rose Stella. The second prize was withheld, and the third went to Mr. Wheeler.

In the nurserymen's class for six Zonal *Pelargoniums* in 6-inch pots, Mr. W. Paul exhibited some small plants of fine varieties. Among these were Surpasse Beauté de Suresnes with beautiful lilac-rose flowers, with a white blotch at the base of the upper petals; Gloire de Douai, brilliant orange scarlet, and the flowers in large trusses; Aurora, rosy salmon, and Madame Thibaut, deep salmon. In the corresponding class for amateurs, third and fourth prizes were awarded respectively to Mr. August, of Beddington, and Mr. G. Wheeler, the first and second being withheld. The best single specimen came from Mr. Weston, being a plant of White Tom Thumb, measuring 4 feet across, in fine bloom. Mr. Wheeler was second with La Peyronne.

Among miscellaneous subjects, Messrs. Lee exhibited a fine group, which has been already referred to, consisting of Orchids, Heath, fine-leafed and flowering stove and greenhouse plants. The same firm also furnished *Hemerocallis* Kwanse, with leaves boldly striped with white, a pretty dwarf gold-variegated Box, *Rhus glabra* with handsomely cut leaves, a *Tropaeolum* with showy yellow flowers and small glaucous foliage, and *Acauthopanax variegata* with small leaves neatly marked with cream-coloured variegations. Messrs. Downie, Laird, & Laing sent *Caladiums*, among which was M. Kolb, light green, becoming of a deeper green towards the edges of the leaves, and blotched with carmine. Messrs. Veitch had new *Dichorisandras*, *Maranta roseo-picta*, *Coffea bengalensis* with pretty white flowers, *Dendrobium crystallinum*, a fine collection of *Gloxinias*, of which Bergerette and M. Brogniart received second-class certificates from the Floral Committee, the splendid *Begonia Veitchii*, and other new plants. Messrs. Veitch also had a collection of *Delphiniums*, of which Madame H. Jacotot and Gigantea were two of the finest. Mr. Sampson, of Yeovil, and Messrs. Windebank & Kingsbury, of Southampton, sent numerous seedling *Pelargoniums* of various classes, and Mr. Turner, Messrs. F. & A. Smith, Messrs. Downie and Co., Messrs. E. G. Henderson, Messrs. Saltmarsh, Mr. Mann, sent several collections of new and old kinds. Mr. W. Paul also contributed several varieties, among which were Jason, Prince Silverwings, Platach, Ronge et Noir, and Goldfinch. These we omitted to mention in the proper place. Mr. Ball furnished new *Coluses*, *Areca Baueri*, and other plants. Lastly, Mr. Green, gardener to W. Wilson Saunders, Esq., sent several rare and curious plants.

FRUIT COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. The Committee met on Monday last at Chiswick to examine the trials of Early Peas, when the following decisions were arrived at, confirming the decisions of last and former years. Sutton's Ringleader, Dillstone's Early, and Carter's First Crop were found to be synonyms.

Dickson's First and Best, Young's Early, Poynter's Early, Sutton's Improved Early Champion, and Taber's Perfection were all synonyms with Sangster's No. 1.

Wheeler's First Early proved to be the same as Dillstone's, or an inferior stock of that variety.

Nutting's Improved No. 1 is a very fine stock of Dillstone's Early. Paul's Tom Thumb is a true stock of the old Tom Thumb.

Stuart & Mein's Improved Early is closely allied to Dickson's Favourite, and only a second early Pea.

Laxton's William 1st. A fine early green Marrow Pea, with a beautiful pod, ripening only four days after Sangster's No. 1, and a week in advance of any other green Marrow.

Laxton's Alpha. The character of this Pea does not yet appear to be fixed, as the pods exhibited a varied character, some being very large, full, and as early as Dillstone's, and others were hollow.

Early Emerald, sent by Mr. Turner, is very much like Little Gem.

Nutting's Maltum in Parvo. This is a first-class early wrinkled Marrow Pea. The plant is of dwarf habit like Little Gem, but with immense pods. A first-class Pea.

Sadbury A1, wrinkled, is a more robust grower than Maltum in Parvo, and not so early.

Nelson's Vanguard was not distinguishable from Climax.

Nutting's No. 1, wrinkled, similar but not equal to Maltum in Parvo.

Nutting's Early Seedling does not differ materially from Maltum in Parvo.

Carter's Dwarf Waterloo is a Pea of the highest excellence. It is a dwarf, 1½ foot high, producing large pods like the Tall Waterloo, and in such abundance as to be quite marvellous.

The Committee again met at South Kensington, on Tuesday, when Mr. Charles Bates, of the Metropolitan Sewage Company, Barking, exhibited a basket of very handsome fruit of British Queen Strawberry, grown under the influence of the London sewage, the flavour of which did not correspond with the fine appearance of the fruit. Mr. Sinclair, gardener to R. Allison, Esq., Woolton Hayes, Liverpool,

sent a seedling Melon which was not of good flavour. Mr. Higga, gardener to R. Driver, Esq., Crabwood, Southampton, sent fruit of the Lognat perfectly ripened and of unusually good flavour.

FLORAL COMMITTEE.—This being the great and special day for the Variegated Zonal *Pelargoniums*, the subjects for examination were comparatively few. Messrs. Veitch contributed new and valuable plants largely as usual. Two *Gloxinias* were selected out of some two dozen varieties and were awarded second-class certificates—Monsieur Brogniart, a curiously-spotted flower; and Bergerette, a soft rose and white flower. *Angraecum falcatum*, a small, dwarf, delicate white Orchid, sweetly scented, received a second-class certificate. M. Verschaffelt sent again his variegated-leaved *Passiflora trifasciata*. This will, probably, prove a valuable foliage plant, and as a climber will be a great acquisition—first-class certificate. Mr. Garaway exhibited three varieties of crested *Athyrium Filix-foemina*, one the usual form cristatum, another *Athyrium F. scopiforme*, the true name, *Thiaptant* received a first-class certificate when exhibited by Messrs. Ivery under a wrong name. Also *Athyrium F. encyphalum*. Both of these received first-class certificates. Mr. Green, gardener to W. Wilson Saunders, Esq., brought four interesting plants which received a special certificate. *Cypripedium arietinum*, a hardy North American plant; *Calliopsis* sp., a bulbous-rooted plant; *Primula sikkimensis*, and a beautiful little Orchid *Promenaea stapelioides*. Each of these plants was very attractive and novel. Mr. Wm. Paul was awarded a first-class certificate for a double *Pelargonium*, Madame Lemoine, a delicate rose and pink-coloured flower. Messrs. Henderson received a first-class certificate for the same. The specimens exhibited by this firm were stronger and larger plants, showing most undeniably that this is a first-rate plant.

Mr. Cole, Worthington Nursery, sent a beautiful specimen of a seedling Fern, *Lomaria gibba crispata*, which received a first-class certificate. Mr. C. Noble exhibited *Spiraea palmata* (Thunberg), a most graceful plant, with deep pink clusters of flowers—first-class certificate.

G. Wilson, Esq., sent a collection of cut *Liliums*, which were awarded a special certificate. Among them were *L. auratum*, *L. longiflorum*, *L. testaceum*, *L. candidum*, *L. japonicum*, *L. aurantiacum*, and two varieties of *L. Thunbergianum*; the *Lilium auratum* were specimens of two distinct varieties. This made a very beautiful group. Mr. Hally, Blackheath, sent some seedling double *Pelargoniums*, but no advance upon those in cultivation. Mr. Mann sent a Zonal *Pelargonium* Countess of Derby, a fine flower, but much resembling Persian and others; it is, nevertheless, a first-class plant and a fine flower, a worthy companion of his lordship. Mr. Turner sent variegated *Pelargoniums*, but none of any great merit. Messrs. Lee also sent a collection of Zonal *Pelargoniums*, and Mr. Stevens, of Ealing, the same. Messrs. Veitch sent *Coffea bengalensis*.

GENERAL MEETING.—G. F. Wilson, Esq., F.R.S., in the chair. The business was confined to the election of five new Fellows.

ROYAL BOTANIC SOCIETY'S SHOW.

The second great summer Show of this Society opened yesterday, and will be continued to-day. In the plant department there is a fine display of ornamental-foliaged plants, of which Mr. Fairbairn, gardener to the Duke of Northumberland, Stion, sends some magnificent specimens; and among nurserymen, Mr. Williams sends fine collections of Exotic Ferns and Palms, besides many other subjects. Of Orchids, Mr. Penny, Mr. Wilson, Mr. Gedney, Mr. Williams, and Mr. Parker have good collections; and of new plants, Messrs. Veitch and Bull send extensive collections. E. J. Lowe, Esq., of Highfield House, near Nottingham, has a very numerous collection of new forms of Ferns; and Mr. Perry, of Castle Bromwich, has a splendid stand of *Verbenas*, in which are two fine seedlings—viz., Mrs. Perry and Florence Fiddian, also Mrs. Turner, Jamaica Birkbeck, W. Dean, and others of his fine new varieties.

Among the stove and greenhouse plants, Mr. Peed has some very fine specimens, especially *Allamanda grandiflora*, and a splendid example of *Dipladenia nassibalis*, on which the flowers are not only numerous but large. Heath is represented in numbers, and among them are excellent specimens. *Pelargoniums* both Show and Fancy, as shown by Mr. Fraser, Mr. Donald, Mr. Nye, and others form a fine bank. Cut flowers, especially Roses, are in great force both as regards numbers and beauty.

Of Fruit there are several heavy Queen Pine Apples, Mr. Ward, of Bishop Stortford, having one upwards of 6 lbs. in weight, and Mr. Barnes, of Bicken, one of 5 lbs. 7 ozs. Mr. Hannan, gardener to R. T. Crawshay, Esq., Cyfarthfa Castle, has a Providence of 12 lbs. 7 ozs., finely ripened, but not quite perfect in the swelling-off at the top.

Of Black Hamburgh Grapes there are numerous splendid bunches, and Mr. Lyuu and Mr. Meads have fine bunches of Black Prince, Buckland Sweetwater, from Mr. Douglas, Loxford Hall, is finely ripened, especially two bunches from a grafted Vine, and with these another bunch from the Vine on its own roots does not compare advantageously. Messrs. Lane also show excellent bunches of the same kind. Fine compact, large-berried bunches of the Royal Ascot are

shown by Messrs. Standish & Co., from Vine grafted in May, 1867. Royal George and Violette Hative Peaches are large and well ripened; and of Strawberries, immense berries of Dr. Hogg are shown by Mr. Douglas, along with President, also large and fine. The Metropolitan Sowing Company send British Queen, also of very large size.

INSECTS.

(Continued from page 419.)

RED SPIDER.—This is one of the smallest and most inveterate of the enemies with which the gardener has to contend. There is scarcely a house requiring fire heat for the successful cultivation of its inmates, in which these do not at some time suffer from red spider. Its attacks are mainly confined to the under sides of the leaves, but if allowed to establish itself it will destroy the young shoots. Whilst deriving food from the plants, it greatly impairs their health and vigour, and in the case of those which bear fruit the flavour of that is to a great extent destroyed. Indeed, if the red spider be allowed to have its own way, the crop will be worth little, and the buds in the axils of the leaves will be so imperfectly formed that they will either fall in winter, or be so puny at the time of flowering that there will be no hope of the blossom setting and of their bringing to maturity a good crop. The vigour of the tree, likewise, is not so perfect in the following year as that of a tree not attacked, for the parasite feasts on the juices of the plant, appropriating to its use that which would otherwise be expended on the formation of buds and the perfection of the current year's growth, and depriving the tree of the stored-up sap on which its vigour in the following year in a great measure depends.

The red spider is of a bright red colour, and has the appearance of a minute red speck no larger than a grain of silver sand. In its young state the insect is pale grey, but varies considerably in colour; indeed, there are several kinds of it. The red is, perhaps, the most common, but is not the most injurious, nor is it so difficult to destroy as the dark grey, which has a whitish head, is far more active, and multiplies with greater rapidity. It forms for itself a web of the slenderest threads conceivable, and marches along its labyrinth with incredible swiftness.

The best indication of the presence of red spider is the upper surface of the leaves exhibiting minute yellowish brown specks, and if the under sides of the leaves are examined there will be found a small red speck, which may, by touching it with the point of a pen, be set in motion. If the specks are more of a blotch than speck, and spreading, it will mostly be found that the specks on the under side of the blotched leaves are not red, but of a dark grey hue, and that they are moving to and fro. The upper surface of the leaves will show the presence of red spider beneath, and when the least sign is noticed, no time should be lost in attempting the destruction of the insect.

Commence by giving a thorough syringing with water, directing its force against the under sides of the leaves, driving the insect and its web off the leaves. This syringing should be given every evening and morning as long as it is practicable to do so without injuring the ripening of the fruit and of the wood. This syringing may be thought injudicious, for some of our best cultivators seldom syringe their fruit trees, but fruit trees which are syringed morning and evening from the setting of the fruit until it swells or changes colour for ripening are never attacked by red spider. I would in all cases recommend syringing where soft water can be obtained, and it may be collected in most places, if provision be made to catch all the rain water falling on the garden structures. There cannot be a doubt that water in some places is not good for syringing with, and especially where it is derived from springs; but even such may be made suitable for the purpose by exposure to the sun and air in an uncovered cistern, and it may be rendered quite equal to soft or rain water by adding one peck of soot to every thirty gallons, stirring the soot well up, and allowing the whole to stand forty-eight hours. Syringe with the clear liquid. Either this or syringing with rain water is a complete preventive to, as well as cure for, red spider.

There are cases in which the water cure cannot be employed, as where syringing one plant attacked would be injurious to other plants in a state of growth for which a dry atmosphere is needed. In the case of a solitary plant being attacked it may be removed, and, if smooth-leaved, like the Gardenia and Fuchsia, it should be syringed with a solution of soft-soap at the rate of 2 ozs. to the gallon, the pot being laid on its side, and the soapy water directed against the under sides of the leaves, the plant being turned round so as to give

every leaf a forcible syringing. The solution should be used at a temperature of 120° for plants in growth, and at 140° for those whose growth is perfected. This application repeated once or twice will free the plants of the insect.

Cucumbers and Melons in frames and pits cannot well be syringed, and other means must, therefore, be resorted to. It is well in all cases where plants subject to red spider are grown, to give the woodwork of the house a thorough cleaning with soft-soap water, using a brush and sponge, and taking care to keep the soap from the glass, which, however, should be thoroughly washed with clean water; and the walls ought to have a thorough whitewashing with equal quantities of lime and flowers of sulphur, bringing them to the consistency of whitewash by adding a solution of soft-soap at the rate of 2 ozs. to the gallon. This is a good preventive, and yet not always effectual. If the red spider appear fill the evaporation troughs, if such exist, with guano water, 1 lb. being dissolved in a gallon of water, and as it evaporates replenish them, and keep them full for three weeks. This effectual cure was first brought into notice by Mr. D. Thomson, of Archenfield. It is eligible for all descriptions of houses having evaporation troughs, and where there is none the paths may be kept wet with guano water. This sprinkled over the paths, walls, and put in the evaporation troughs, is an excellent preventive, and increases the vigour of the plants. Four ounces of Peruvian guano to the gallon will be sufficiently strong, and yet safe.

If there are no evaporation troughs and red spider appear, mix 1 lb. of flowers of sulphur with 1 oz. of gum arabic dissolved in a quart of water, make into a paste, and add to three gallons of water. Syringe the plants on a fine afternoon with this liquid so as to wet them thoroughly, shutting the frame close, and shading to prevent the leaves being scorched. The syringing may take place at 2 p.m. if shade can be given, but an hour later if none can be afforded. The sides of the frame or pit should be painted on the inside with a composition of sulphur brought to the consistency of paint by the addition of 4 ozs. of soft-soap in a gallon of water. This must be kept from the leaves of the plants, as soft-soap will destroy the foliage. Shut up early for a fortnight afterwards, and repeat the syringing with sulphur water within a week if it has been washed off the leaves in watering. This is an effectual remedy for red spider on Peach trees, whether in houses or against walls, adding 2 ozs. of soft-soap to every gallon of water, but omitting the soft-soap if the fruit is more than half swelled. This remedy must not be employed for Vines.

I will now say a few words in favour of a cheap remedy, and, I think, the best of all applications for destroying red spider—viz., soot. One peck of soot in thirty gallons of water applied every evening with a syringe for three weeks is a cure, and dusting the leaves with dry soot till they are quite black is still better, the foliage being previously wetted. For Strawberries in pots or in the open ground there is no better cure than strewing soot over the plants and soil till the whole is quite black. Violets, too, so liable to red spider, are effectually freed by a thorough dusting with soot, and it is a remedy, unlike many others, that acts as a manure. For this remedy I am indebted to the Journal and the Rev. W. F. Keadylyffe.

Opposed as some are to syringing Vines, and as it cannot always be practised upon them, other means must be adopted, though I never saw the least injury result from a daily syringing with clear soft water from the setting of the fruit up to the time of its changing colour, except where air has not been given early; then I have seen the leaves scorched and the berries spotted, but quite as often when no syringing was practised, for condensed moisture on the leaves and berries is as frequently the cause of scorching and spot as moisture from syringing, if not more so. Preventive measures being always the best, the house ought every season before the Vines are started to be thoroughly cleaned, the woodwork washed with soap and water, the glass cleaned with water only, for soapy water ought never to touch glass, and the walls should be washed with sulphur and lime in equal proportions, brought to the consistency of whitewash by adding 2 ozs. of soft-soap dissolved in a gallon of water. In addition to this I would strongly recommend keeping the evaporation troughs filled with 4 ozs. of guano to the gallon of water, sprinkling the floors at least once daily with the same liquid. Should red spider appear notwithstanding these precautions, a paint should be made of sulphur and 2 ozs. of soft-soap to the gallon of water, and the pipes being heated to a temperature of 140° or 150°, coat every part of them with the sulphur paint, and then

sprinkle them with water of the same temperature as the pipes until the house is full of steam and sulphur fumes. The house, of course, must be shut up closely. This may be repeated if necessary within a week. It is not necessary to syringe the Vines, but it may be done if the state of the crop allow. The walls should be painted with sulphur and soft-soap water, 4 ozs. of the latter being dissolved in a gallon of water. This paint must not be put upon flues unless it is quite certain that they will never be hotter than 160°, for should the sulphur ever burn it will destroy the foliage and, of course, the crop.

To destroy red spider in houses having no heating apparatus, the following method will be found effectual:—Take some 11-inch flower-pots, half fill them with fresh lime (unslaked), and place one at each end, and the others 8 feet apart along the front of the house. Pour water over the lime so as to cover it, and sprinkle a small handful of flowers of sulphur in each pot. In the morning syringe thoroughly, but if syringing cannot be practised, as when Grapes are ripening, make the floors, walls, and other surfaces quite wet. This is an excellent remedy but requires care, as if the sulphur ignite the foliage will be scorched. Be careful, therefore, not to put in too much sulphur, and to give enough water to the lime to thoroughly slake but not drown it.

Water is the natural enemy of red spider, it will prevent and destroy it. A moist atmosphere and a plentiful supply of water and nutriment at the root are the best means of preventing the attacks of this insect, and these conditions being afforded red spider will not be difficult to get rid of.—G. ABBEY.

(To be continued.)

NOTES AND GLEANINGS.

On more than one occasion we have asked for the attention of our readers to the LINDLEY LIBRARY, and we now place before them this circular recently issued by the Trustees. If they would publish a list of the works already in the Library, donors would know which to present that would not be duplicates.

“Notice is hereby given, that the Committee of the International Horticultural Exhibition having offered to invest the balance of the profits realised by that Exhibition over £1850, after presenting £1000 to the Gardeners' Benevolent Institution in the purchase of books to form a library in connection with the Royal Horticultural Society, and to be called the 'Lindley Library,' in testimony of the respect in which the late Dr. Lindley's memory is held, on the condition that the books so purchased, and any others which might hereafter be presented, should be vested in seven Trustees, and that the books should, under rules, be available for the use of the Fellows of the Society, and other horticultural students,—the Council agreed with pleasure to accept the offer, and appointed W. Wilson Saunders, Esq., a Vice-President of the R.H.S., John Clutton, Esq., the Hon. Treasurer of the R.H.S., Col. H. Y. D. Scott, R.E., the Hon. Secretary of the R.H.S., as their three Trustees; and the International Committee appointed Dr. Robert Hogg, Dr. Maxwell T. Masters, and Thomas Moore, Esq., to represent them; and the six having agreed, nominated Sir C. Wentworth Dilke, Bart., M.P., as the seventh, and the trust-deed has this day (May 5th, 1868) been signed. The first purchase made by the Trustees is Dr. Lindley's Botanical and Horticultural Library, at a cost of £600, and steps are being taken to make the library available. As the Trustees are unanimously of opinion that the addition of such a library to the Horticultural Society would be a great boon to students of Horticulture and Botany, and also materially promote the best interests of the Royal Horticultural Society, and as the Trustees wish to make it as perfect as possible, they think it right to call upon the Fellows of the Royal Horticultural Society to aid them with funds and presents of books, to extend the usefulness of the library which has thus been commenced.

“The Trustees have the gratification of being able to announce that Her Majesty the Queen has been graciously pleased to present to the 'Lindley Library' a botanical work of the value of twenty-five guineas.

“The Trustees are also happy to be able to state that already several Fellows of the Society, and other gentlemen, have promised valuable assistance, amongst others—

George Bentham, Esq., Pres.
Linn. Soc.
Rev. M. J. Berkeley
Messrs. Bradbury, Evans, & Co.
John Clutton, Esq.
Sir C. Wentworth Dilke, Bart., M.P.
W. M. Flaggate, Esq.
Dr. Hogg
Dr. Joseph D. Hooker, F.R.S.
G. W. Johnson, Esq.
Thomas Lee Esq.

N. Lindley, Esq.
Dr. Maxwell T. Masters.
Thomas Moore, Esq.
Prof. E. Morren, Liege.
W. Wilson Saunders, Esq., F.R.S.
Col. H. Y. D. Scott, R.E.
M. Henry Villard, Paris.
D. S. Williams, Esq.
Mrs. C. A. Chetfield, and
Mrs. Inwood Jones.

“Any presents to be addressed to The Trustees of the Lindley

Library,' Royal Horticultural Society, South Kensington, London, W.

THOMAS MOORE
W. WILSON SAUNDERS
H. Y. D. SCOTT.

“Trustees of the Lindley Library.”

— EVERY gardener knows the “Wardian case,” by the agency of which living plants have been introduced after half circumnavigating the world, and which had defied all efforts to preserve them, until that case was invented. Its inventor, NATHANIEL BAGSHAW WARD, died on the 4th inst., at St. Leonards, aged 77. He had been Master of the Apothecaries' Company, and one of its Examiners, for which duty he was additionally qualified by his botanical knowledge. He was also a Fellow of the Royal, the Linnean, and other scientific Societies, and for forty years vaccinator to the National Vaccine Establishment. He resided successively in Wellese Square, and Clapham, and in his houses he most strikingly demonstrated how healthfully plants may be cultivated in confined spaces, and in the smoky atmosphere of a city. He published “Observations on the Growth of Plants in Closely-glazed Cases.”

WORK FOR THE WEEK.

KITCHEN GARDEN.

EVERYONE who has had the benefit of the late rains will be planting, sowing, and thinning. As soon as convenient let the surface of the ground be well stirred with the hoe or fork, to prevent the moisture evaporating. The late very dry weather will have forced several matters upon the consideration of many, such as the importance of so choosing the site of a garden as to have a plentiful supply of water: the construction of tanks in gardens to receive the water from drainage, hot-houses, and frames. It is an ascertained fact, that in general as much rain falls on a dwelling house as will supply the inmates during the season. Why should such a fact not be taken advantage of in gardens? In most pit and frame grounds much valuable water is lost every heavy rain, which would be of great service for summer crops. The past season will likewise have demonstrated surface-watering to be insufficient, the importance of keeping the surface of the soil loose, and the great advantage of digging or trenching deeply for all the main crops. About the end of June and beginning of July, as the early Peas and Beans are cleared off the ground, is the usual time for planting out *Broccoli*, *Brussels Sprouts*, *Savoy*, &c.; but if room is scarce these may be planted out between the rows of standing crops that are expected to come off soon. No one ever thinks of planting any of the Cabbage tribe without first manuring the ground. *Calcivorts* are much sought after in places, but in some families they are never used. This is about the time to make the first sowing of them, and in many late situations it is high time to sow *Cabbages* to come in early next spring, but in good situations a fortnight hence will be time enough. *Celery*, another trench or two may be planted out, but a fortnight hence will be time enough for the main crop in most places. *Peas* and *Beans*, the earliest varieties of these should now be sown for the last time, but some Early Frame Peas may be sown as late as the second week in July, and if we have fine weather in October they will afford some dishes which will be very acceptable.

FRUIT GARDEN.

If the tops of shoots of Currants or Gooseberries should become infested with insects, as they often do about this time, the best way is to cut off the tops at once, which will do no harm to the bushes so late as this in the season. A good washing with the engine occasionally will be of service to the wall trees, and unless they are attacked by insects clean water is as good for this purpose as any mixture. See that the Vines never get loose or grow so long before they are tied in, and so with all wall trees. Put down the shoots of Cucumbers and Vegetable Marrows under hand-lights.

FLOWER GARDEN.

Everywhere in the flower garden the greatest order and neatness should prevail; not a dead or falling flower should be seen, not even in the wildest corner of the shrubberies. No plants requiring support should be a day without a new stick. The flowering of many of the annuals may be prolonged if their seeds be cut off as they begin to form; some, again, would do better if the strongest shoots were cut back all

over the bed or row. Never let *Salvia patens* come up with a centre stem; pinch this off close to the bottom, and half a dozen shoots will spring up instead of one. This is better than thick planting. Some people treat Hollyhocks in the same way, and by that means obtain great masses of late-flowering shoots. Chrysanthemums which have been planted out and are now growing tall may have their branches regularly pegged-out, so as to have the tips turned up preparatory to their being layered towards the end of next month. Continue to prick out seedling Auriculas in pans or boxes, shading them from the sun. Polyanthus may be parted now in showery weather, renewing the bed with decayed cow manure and leaf soil. The general collection of Tulips may now be taken up, provided the foliage has assumed a yellow hue; shake the soil from the roots, but do not yet remove the fibres or outer skin from the bulbs. Place them in their respective compartments in boxes, and wrap them in very thin paper. The late drought has been seriously against the Ranunculuses; any of which the foliage has begun to decay must be immediately taken up, or rainy weather will cause them to start again to their almost certain destruction. In sunny weather dust any of the flowers which it may be desired to seed with the pollen of the best-formed semi-double flowers that can be obtained. Follow the directions given last week as to Carnations, pinching off the laterals, disbudding, tying, keeping free from aphids if possible, &c. Put in pipings, marking each lot of cuttings, so that when the layers from which they are taken bloom, if they should chance to be "run," or full of colour, the pipings from such foul flowers may be destroyed.

GREENHOUSE AND CONSERVATORY.

Common Pelargoniums are now being struck from cuttings in the open ground round London, in multitudes. The old plants might also be shaken out of their pots; and planted in the open ground, to be taken up early in the autumn, so as to have them well established in the pots before winter, they would make excellent plants for forcing next spring. The mid-summer cuttings will make strong plants by next October, and if they are well encouraged early in the spring, they will make beautiful flowering plants by this time next year. All the best varieties of the Chinese Primrose should now be divided and planted out in a shady situation, in very rotten leaf mould, to be taken up next September for winter flowering. Seedlings of them should also be planted out now in spare pits, well shaded, there to remain till they all flower, when the inferior sorts may be thrown away. All the best specimen plants are still to be kept in-doors in the greenhouse, but the paths are flooded over every evening to keep the plants in a moist atmosphere, and when a portion of the hardier stove plants are introduced among them, the doors and ventilators had better be shut up late in the evening. All the coarser plants being now removed out of doors, more attention must be paid to the watering of the more delicate plants which are kept in-doors throughout the season; train out and stake them till you have them handsome in shape.

STOVE.

This is about the best time to perform any necessary repairs, painting, &c., as the greater portion of the plants may be safely removed into other houses; indeed, all plant houses ought to have a slight coat of paint annually. Any moveable sashes may be done from the outside, by turning them on purpose. The lights of pits or frames at work may be painted at any time in dry weather, by turning them in the same way. Many of the softwooded stove plants flower best while they are young, and about the end of June is a good time to propagate these for flowering next season. Plants in this house have their young wood so well hardened that they may have air largely every day. There is hardly a week till the beginning of August in which some plants will not want a shift into a larger pot.

PITS.

Prepare to make in these useful structures, a large plantation of choice and dwarf young plants turned out of their pots for two or three months, in suitable composts. One who has not seen the good effects of this plan can hardly conceive the improvement it makes in the plants, particularly on Heaths, Epacris, and other delicate plants which are difficult to manage in dry, hot seasons under the ordinary pot culture. It is advisable to syringe all plants here in the afternoon, and to leave the lights off at night where the hardier plants are, and only put them on about breakfast time. Most pot plants require to be somewhat screened from the sun out of doors for a few weeks, till the nights become a little longer, when the dews will, in a great measure, counteract the effects of strong

sun. For growing a stock of young plants in summer no structures are so good or economical as pits properly constructed. Place the pots on a bed of sifted coal ashes, and if clean moss free from slugs can be procured, it is an excellent plan to place a thin layer of it between the pots. After it is well damped you have a source of constant moisture, which, passing up among the foliage, is very beneficial to all plants in summer, and they require less shading when they are thus managed.—W. KEANE.

DOINGS OF THE LAST WEEK.

FITCHEN GARDEN.

FROM want of rain, Peas and some other crops are suffering, but less than might be expected in the scorching heat. With Peas and young Cauliflower plants our chief means of counteracting drought was *mulching* with grass and dry litter. In some cases, as with young Turnips, we shook dry litter thinly over the foliage to arrest the evaporation, and yet allow enough of light to pass to keep all healthy. A heavy shower would place the most of this sprinkling away out of sight close to the ground. Our strong Celery would have been planted out long ago but for the drought and the scarcity of water, as it is easier to water it when it stands thickly than when planted out in beds or rows. Lettuces we have sprinkled overhead thinly with clean litter to keep the moisture of the earth from so freely escaping, and gave a little water when it could not be avoided. In sowing Turnips, Lettuces, Radishes, &c., we have watered the rows after the drills were drawn, sown the seeds, covered them with the drier earth, and then covered all over with litter or mats until the seedlings appear. This plan is in many respects better than watering the ground on the surface, saves much watering, and secures moisture for the roots for a considerable time, even if the surface soil should become dry. If that surface be kept loose this watering the drills before sowing often saves all watering afterwards. Peas are generally treated in this way, and when well drenched they do all the better in such scorching weather if the surface soil is composed of dry earth rather fine and loose, which acts like a mat or other covering in preventing the moisture from so freely escaping. We never had first and second crops of Cauliflowers better, but they were mulched well with short dung, and then with dry litter wrought up as far as possible among their stems and on the ground immediately contiguous, so that the moisture that was evaporated was chiefly that which transpired from their large leaves. Potatoes are doing well.

Water and Watering.—Such seasons as this show clearly the impropriety of having large gardens in positions where little or no water can be depended on, except that which falls directly from the clouds, and must be secured in ponds and tanks. In all such cases, to keep plants at all near the mark, extra care and watchfulness and much extra labour are demanded. With all our care to lessen the necessity of watering, the indispensable watering is a heavy item of labour, as all the water must be wheeled in water barrels, and often brought from a distance in a horse-and-cart large barrel. In the latter case, to make the most of the horse, much labour must be employed to empty the barrel quickly, and in such a case water must often be applied at anything but the best time for watering, as the nearer the evening it is now applied the greater will be the effect of the watering, whether under glass or in the open air. We have watered in the open air during a scorching sun, merely to keep plants from suffering; but if even dry earth was placed over the moist, the water too quickly found its way into the atmosphere without the plants deriving the benefit which they would have done if they could have absorbed it quickly after the sun was getting low.

By means of piping in connection with a pump and pond we hope to lessen the labour of carrying and wheeling, but even then we shall be far behind those places where the watering chiefly consists in fixing a hose to a tap and so taking the water to where it is wanted. This, without great expense, cannot be done on the highest ground in the neighbourhood unless there is a stream in the valley, from which water may be sent by means of a water ram constantly at work. In all new gardens of any extent the water supply should form a subject of primary consideration. In these days of economy people are apt to compare the expense of one garden with that of another something similar in size, but they are very apt to overlook the great difference in labour when few and many crops are grown in winter, or when a house is appropriated to one purpose or to many purposes, there being in the latter case

a great increase of labour involved in moving; and secondly, they are very apt to forget the difference in watering, when water has to be carried into the garden, into houses, &c., and where little more is required than the dipping of a pail, or the turning of a tap.

As a matter of economy it is of first importance then in every glass house, or at least in every short range, that there should be a water supply. As respects ourselves, could we depend on the supply from ponds, and that could be done by increased drainage, a greater supply of piping from an elevated cistern filled by a force pump would in a short time save in labour all the expense for piping, cisterns, &c. We are no great admirers of merely having a tap in a house from which water may be had at pleasure. If the cistern is so elevated that you can apply a small hose on the top and merely have to walk round the house with the hose to give all the watering, all is well; but if the tap is merely to fill pails as wanted, there is apt to be a waste of water, or a waste of time in waiting for the pail filling, but all this is avoided when the pail is filled at once by a dip in a cistern or tank. On the same principle we look on a tap in a water barrel, to be wheeled by a man, as a nice-enough contrivance for an amateur, or a lady or gentleman, but quite unsuitable for a workman, who, by dipping, or turning the barrel on the pivots on which it is hung, would empty the barrel whilst a pailful or two were running from the taps. All such matters prove the importance, not only of a water supply, but having it so fully at command as to involve the least amount of labour, for in many seasons where all water must be carried, the cost of watering must be very great. The position of a garden is, therefore, of much consequence. On elevated ground there is less risk from spring and autumn frosts, but there is a greater risk of suffering from summer droughts, unless there are means of securing the rainfall, or of bringing water up the hill.

We must not omit to mention, that where water is most abundant there is a danger of using it too freely. We have seen crops in kitchen gardens suffering from almost a flooding daily with water from the hose fixed to a pipe. We have seen flower beds drenched in June and July by the same means from an elevated cistern, and yet they did not look any better, nor so well, in fact, as beds the plants in which had merely a little water at the roots once or twice a-week, and the surface stirred to keep the moisture in. We saw a year or two ago a flower garden watered overhead every night, and the plants were anything but flourishing in the baked caked soil. All such matters require discretion, and the injury done was most likely owing to the cold produced by evaporation in somewhat unnatural circumstances, as when we have natural waterings by rain we have the cloud that arrests evaporation, a very different affair from a wet soil and a scorching sun. Be this as it may, the facts remain, that it is of first importance in a garden to have water at command, as the ease and the difficulty in its application make a great difference in the labour necessary.

As regards *manure watering*, three or four cases have been brought to our notice of the injury done to plants and fruit trees from an over-dose of rich liquid. One person emptied the cesspools of a large stable on his Vine border, and apparently the roots will never want another watering. Another watered Cauliflowers freely with gas ammoniacal water, and they died by degrees, and left nothing for the cooking pot; and here is another correspondent who has ruined some fine Peach trees in pots, because he watered them from a cesspool connected with a stable, believing that the stronger the liquid was the better the trees would like it. From what we have seen of such liquid, altogether free from a drop of ordinary water, we would not have applied it without the addition of from six to ten times the quantity of pure water. The lesson to be learned from all this is, to make sure that all manure water is weak enough not to injure the roots. It is better to give it often, instead of too strong at any one time, and just as it is well for us to change our food, so plants like a change in the quality of their water. Soot, the droppings of different animals, superphosphates, guano, &c., furnish plenty of variety. If droppings are used fresh, they should ferment in the water for some days. Guano is safer used at the rate of an ounce to a gallon than stronger, if it is really good.

FRUIT GARDEN.

We have netted all our Cherries and all the earlier Strawberry, or the latter would never have been allowed to ripen; this, as already referred to, being the first time that we have noticed green Strawberries eaten and carried off in quantities. For the last few days our flocks of thrushes and blackbirds

have decreased, and many that appear are very weakly—scarcely deeming it worth their while to get out of the way, which we attribute to two causes—the green fruit not agreeing with them, and the great difficulty they must have in getting more nourishing soft food in the way of worms, slugs, snails, &c. Keens' Seedling Strawberry is now coming in; and just before it President and British Queen are doing good service in the front of the latest orchard house.

In the orchard house we dashed the glass a little with water just whitened, to lessen the quantity of water that would otherwise be needed inside; and though giving air early, we seldom opened the ventilators fully in front, as the less draught prevented such rapid drying. In the hottest days we sprinkled at midday the ground and the lower part of the trees in pots from the syringe, which cooled the house considerably. With abundance of water at command we should not have dulled the glass, though with large squares it is no bad plan in such scorching weather. Provided air is given early or left on constantly, we are not afraid of a high temperature during the day. We have finished some of our Cherry trees in pots, which were heavily loaded; and others are coming in rather too heavily cropped, and would have been better if more thinned. Plum trees in small pots are very heavily laden with fruit, and we have done little in thinning it. As we expected, some have dropped and saved us the trouble; but to have fine fruit we must thin. These trees have all been well mulched, as stated lately; and now and then we throw as much soot as can be held with the thumb and two fingers over each pot—say once in ten days, alternating it with as much of dissolved bones or superphosphate. These trees in pots we should like to pot afresh this autumn, if we gave them no larger pots, as they have not been potted for a number of years. We believe they might remain in the same pots for many years by top-dressing every autumn. The pots are fully half-plunged in the border to save watering, and all they have hitherto had done to them is merely lifting them up every autumn, so as to break all the roots that had run through the bottom of the pot in summer.

Proceeded with thinning late Grapes as we could get at them. The Peach house yielding nicely we sprinkle several times with water along the floor and path in the hottest days, and give plenty of air, netting the openings as the blackbirds had begun on the soft Peaches. Vineries have had no syringing, but the paths and stages were damped in the hottest days, and in the house where Grapes are coming in a little air is left on all night, and this prevents condensed moisture lodging on the berries. Many years ago we called on a friend one Sunday morning; he did not get up early that morning, and on entering the vinery the Grapes nearest the top of the house, nearly ripe, were found to be very wet. The sashes were drawn down to admit plenty of air, and the rapid drying of the bunches left watermarks on them, which disfigured them for the table. If a space of from half an inch to an inch had been left open all night at the top of the house for air, such condensation of moisture on the bunches would have been prevented.

ORNAMENTAL DEPARTMENT.

A trying time it has been for bedding plants. Some of our Pelargoniums lifted out of earth beds have shown a few withered leaves, and as yet we have allowed them to remain, as they shade the stems and the ground a little. With the little water at our command the plants on the whole have done very well, we rather think better than where they were watered every day in such weather. Even Calceolarias are holding their own well; but in their case we have commenced mulching the ground about them with a little rotten dung, which will keep the roots cool and moist. Give the Calceolaria coolness and moisture at the roots, and then it will be the better of all the sun it can get. We find that with our small supply of water carefully given the roots of the plants are pushing well, and the buds along the stems are nice and prominent, only waiting for a change of weather to throw out a profusion of short stubby flowering shoots. Pinks and Carnations we would have watered well if we could, but we have been forced mostly to content ourselves with surface-stirring.

How deliciously the air is scented with Pinks just now! They and Carnations and Picotees are best supported with twisted wires, as then no tying is necessary; all that is required is to place the stems in the twists of the wire, and they are held securely. For fine flowers the pod should be tied to prevent splitting. Cuttings or pipings should now be made, and the quickest way to do so is to catch the shoot with the left hand, and pull out the point of the shoot at the second joint with the right hand, when in general the cutting will be fit to im-

sert, and the old plant will be little disfigured, as the leaves conceal the wound made by pulling the cutting out at the joint. A shady place, a sandy soil, and a hand-light are the best conditions for insuring success. In a sunny spot shade during the day, and give a little air at night.

Ranunculuses will now need a considerable quantity of moisture. A firm, moist, well-drained soil is their delight. One of the best methods for securing these conditions in such weather is to loosen the mere surface, make some holes in it, and water the soil well, touching the leaves with the water as little as possible; and then as the surface becomes rather dry, cover with riddled rotten dung. This will keep the roots moist without the necessity of wetting the foliage.

As soon as possible we will have verandahs, corridors, conservatory, &c., fresh arranged, and thus get many Pelargoniums of the florist and fancy kinds out of doors, first in a shady place, and then in a sunny spot to harden the wood. Azaleas now in corridors will be removed to the conservatory, where they can be kept a little closer by themselves. In limited space it is impossible to give just what such plants like now without injuring others. Even an unheated glass house would suit such plants well that had growth to make, as a close moist atmosphere could be kept about them, and more air when needed. The sun can now make any place under glass a hot-house. A cold pit for grafting, inarching, and other purposes, in such weather is just as good as a hotbed.—R. F.

COVENT GARDEN MARKET.—JUNE 17.

HEAVY arrivals of rough goods are now coming to hand daily, much in a poor condition for want of rain. Strawberries and Cherries have also largely increased in bulk, and the demand for them has been very steady, and most of the stands have been cleared.

TO CORRESPONDENTS.

... We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

ADVERTISING HORTICULTURAL BOOKS.—"Is it not a very short-sighted policy on the part of booksellers, publishers, and authors of horticultural, &c., not to advertise their works? Many books on such subjects are reviewed by you and other journalists, but it is vain to look in your columns for an advertisement of the books themselves, and many parties, of course, would not run the risk of ordering books without knowing the price of same. I could quote endless instances of the want of information on this point.—W. H. B."

BOOKS (T. H. Donnan).—Keane's "In-door Gardening" details the management of stove and greenhouse plants. You can have it free by post from our office if you enclose twenty postage stamps with your address. (*A Young Gardener*).—Read Johnson's "Science and Practice of Gardening," and the "Cottage Gardener's Dictionary." If you write to Mr. Richards, Assistant Secretary, Royal Horticultural Society, South Kensington, he will give you information relative to the examinations. The two books we have named can be had from our office, post free, if

you enclose 2s. in postage stamps with your address. (P. Y.).—Lance's "Hop Farmer" is the only modern work on the subject that we know. (C. R. H.).—Lowe's "British Ferns" will answer your purpose.

GRAPES CRACKING (J. B. Chilton).—Your Grapes were so smashed in the letter we had difficulty in making anything of them. They appear to have what is called rust, and the tissue being hard and dry will naturally crack. Give air cautiously, and do not allow a cold current to pass over the Grapes early in the morning.

CHASSELES NAPOLÉON OR BICANE GRAPE (T. E. Partridge).—Mr. Knight is not a nurseryman, but now gardener to the Duke of Roxburghe. If you write to Mr. Rivers you may procure it from him.

MILDEW ON GRAPE (A Subscriber).—We have repeatedly eradicated the mildew from the berries by literally covering the bunches with flowers of sulphur in a soap plate held beneath them and rolling the bunches in them. The sulphur may also be dusted over the leaves, and the stems painted with a mixture of clay and water. The mildew berries will crack if they are not sulphured.

VINE LEAVES DISEASED (W. R. Lancaster).—Your Vine leaves are very curiously affected. It is a tendency to fasciation of the three principal veins in the middle of the leaf. It is very curious, and we shall have the matter investigated. Do not the Vines exhibit languor in their growth?

VINES IN AN ENGINE HOUSE (T. H. B.).—We would water the Vines outside, and in this hot weather we would damp the tiled floor inside the house, at least at midday, or whenever it dries quickly.

VINE CULTURE (P. S.).—You may now discontinue fires, the house being closed early, and a little air should be given all night. In dull damp periods a gentle fire or bed will do good, and especially later in the season, to thoroughly ripen the crop and wood. The stages, floors, &c., should be kept damp until the Grapes are advanced in ripening, and syringing the Vines in the evening with clear soft water until the berries change colour for ripening, air being given early in the morning. Good root action and the thorough maturation of the wood are essentials of Vine-growing. The Vines may be pruned as soon as the leaves have fallen.

AZALEA CULTURE (Idem).—Azaleas require to be placed in a house where there is a gentle heat, either flowering, and should be kept there until they have made good growth and have set the flower buds. In a house devoted to them the atmosphere, after flowering, should be kept closer, and moisture should be given abundantly. This is not the treatment required for Heaths, and we do not consider Azaleas and Heaths succeed well together. Azaleas should not be turned out of doors after they have made their growth, but be kept in a cool, well-ventilated house. Placing them outside will tend to keep down thrips, but it is not desirable to turn them out of doors in summer on that account; indeed, it is a bad practice.

MAGNET IN ONIONS (Idem).—Soot applied to the ground, giving a good dressing, so as to make the surface quite black, is the best preventive. It should be gently pointed in prior to sowing. There is no remedy; but as soon as the presence of the insect is detected, those plants of which the leaves have flagged and are turning yellow should be pulled up and burnt, and the beds watered with lime water, 10 lbs. of fresh lime being sufficient for thirty gallons of water, or the beds may be well watered with strong soap-suds, and then sprinkled with soot so as to make the surface quite black.

CAMELLIAS IN POTS AND IN BORDERS (Idem).—Camellias thrive quite as well planted in borders as in pots; good management is all that is required in either case, but there are instances when the best cultivators at times fail.

GRASSES (L. R.).—We know of no better volume on English and foreign Grasses than that by Miss Flax.

HOT-WATER HEATING (Idem).—We do not know any dealer in second-hand boilers. From 60 to 90 feet of 4-inch piping would heat your house if you did not propose forcing. Those who advertise in our columns would be the best to refer to. A small saddle-back boiler, new, would cost from 50s. furnace fittings 30s., and piping from 9s. to 1s. per foot, with extras for curves and bends.

GREEN COLOURING FOR GRASS (M.).—We cannot tell what the green coloring matter is which you saw on the glass of greenhouses in a nursery in your neighbourhood, but green colour mixed up with size water or even with milk will be the most of the summer. We have seen blue used with good effect, and would be glad to know what cheap colours could be safely and most easily obtained.

PEACH LEAVES BLISTERED (L. Hutton).—The leaves of your Peach tree are blistered and mildewed. Apply flowers of sulphur.

CUTTINGS OF PELARGONIUMS (L. H.).—We do not know where you can get cuttings of Variegated Pelargonium. You should try some florist.

MILDEW ON FERNS (G. J. S.).—Mildew on the stems is generally caused by the plants being kept in a close and a atmosphere. It may be destroyed by dusting with flowers of sulphur the parts affected. Mildew seldom shows itself on Ferns that we should be obliged by your sending us a frond with its stem infested with mildew as you describe. We make no charge for answering queries.

NECTARINES CRACKING (T. H.).—We should advise you to syringe only in the evening. Nectarines are much more apt to crack than Peaches. Probably the foliage of the trees is very dry, and the sun's rays fall directly on the fruit. In that case we would shade the portion of roof over them for a few hours, when the sun's rays fall not directly on the trees, and confine this until the fruit begins to ripen.

WOODLICE IN HOTBED (T. H. B. Don).—The "spiders" we think are woodlice. Nothing is so effectual as to tread the sides of the frame inside, making the soil very firm for a distance of 4 inches or so all around; and the first thing in the morning pour strong water against the sides of the frame inside, and on the floor portion of the bed. This repeated occasionally will thin their numbers considerably, and a board placed in the frame would keep them down.

ROSES AT PARIS (Kingsbridge).—The first fortnight in July is too late in any year to see the best gardens in the neighbourhood of Paris, but we may see in this exceptionally early season. The most worthy of notice are M. Charles Verdier and M. Eugene Verdier at Ivry, and Mons. Margottin at Bourg-la-Reine, the latter one of the best rosarians, and an hour's chat with him is a great treat. We hope for notes from an earlier visitor.

PLUM-TREE LEAVES WHITENED (T. G.).—The whitish or glaucous appearance of the trees sent us we think is caused by the late powerful sun heat, and the tree being in want of water at the root. We think a few good soakings of water at the root, and a thorough syringing with an infusion of 2 ozs. of tobacco in a gallon of water, would free the tree of the few aphides which we think exist on the tree; or you may syringe it with a solution of 2 ozs. of soft-soap to the gallon, and give a good syringing with clear water as often as you find convenient. There is no appearance of disease in the leaves sent, only there are traces of aphides.

SEWING AURICULA SEED (E. R. B.).—The seed should be sown in good time, say the beginning of March. The seed pans should be well drained, and filled to within an inch of the rim with rather light turfy loam merely chopped with a spade, so as to make it rather small, then fill to the rim with finely sifted soil to which has been added a little well reduced leaf mould or old manure. Give the pan a gentle tap on the potting bench, and make the surface quite smooth by patting it gently with the bottom of a small flower pot. Scatter the seeds tolerably thickly, and cover with not less than the eighth of an inch nor more than the quarter of an inch in depth of light soil. A gentle watering should be given, and the soil should always be kept moist but not wet. Set the pan on the front shelf of a cool greenhouse, cold pit, or frame; place it near the glass, and where it will not be shaded in any way. If the seed is good the seedlings will make their appearance in a month after sowing, but it may be more; and in eight or nine weeks they will need to be removed to a more shady situation, where they can have the sun up to 9 or 10 o'clock A.M., and be shaded during the remainder of the day. Keep them well supplied with water. At the end of June or early in July they should be pricked-off in a shady situation, planting them about 3 or 4 inches apart, and giving a gentle watering. Water moderately every two or three days during the summer.

HOUSE FOR CAMELLIAS (T. G.).—We should prefer the house upon which the sun's rays strike all day. The Camellias, and such Rhododendrons as Nuttallii and Edgeworthii, would succeed well in the same house. You can shade the cuttings, or have a glazed case within the house, which would be best, as the Rhododendron must have plenty of air.

BERBERIDOPSIS CORALLINA, and POINCEANA GILLESII CULTURE (T. G.).—Berberidopsis corallina succeeds admirably in a cool house, and in a compost of two-thirds fibrous loam and one-third sandy fibrous peat. It also succeeds against a wall in sheltered situations in the open ground, and is one of the handsomest evergreen shrubs introduced of late years. Poinciana Gillesii requires a cool house, a wall with a south or south-west aspect, or a warm sheltered situation. It then grows freely, and is of easy culture.

NARCISSUS ALBUS FLEUUS ODORATUS FORING (J. W. K.).—This very fine and sweet Narcissus may be forced as easily as any of the family, but should not be brought on too rapidly. It should be forced slowly, the plants or bulbs being taken up in October with balls, and potted in pots sufficiently large to hold them well. In November the pots may be placed near the glass in a cool house, and in December should be introduced into a house where there is a gentle heat, not forcing much until the flower buds appear; then give more heat, keep them near the glass, and give air freely. We hardly expect you will have them fine in February, but in March and April they will be very good.

PASSIFLORA MANIGATA (P. J. N.).—Passiflora (Troponia) manicata will succeed in a greenhouse, but not in a cool one, by which we mean a house in which no fire heat is employed. It will do well, however, in an ordinary greenhouse. Had we a border we should plant out, but brick-off a portion of the border so as to confine the roots, otherwise the plant makes growth instead of flowers. It should have good drainage, and be well supplied with water when growing; but when it has made good growth water should be gradually withheld and a state of rest induced, keeping it dry in winter. The shoots should not be allowed to become thick, but be kept rather thin and trained near the glass.

MELONS (Cocah).—These are difficult to keep true, more especially if two varieties are grown near each other. We had several kinds last year from seeds produced by Golden Perfection. We do not know Scarlet Perfection.

CALCEOLIC ACID (W. H.).—See a communication in our Journal to-day.

NEW PLANT (J. L. M.).—There is no rule by which to decide what is a "new plant." One discovered two years before the award was not wrongly admitted.

LONICERA JAPONICA AUREO-RETICULATA (J. Gooden.).—It is blooming, is quite common.

ROSES (James Phillips).—We cannot name florists' varieties. Your seedling is not equal to many others, and would not sell.

WATERING WITH TEPID WATER (Alacer Fallax).—There is an advantage in using heated water out of doors, until, as now, the natural exposed water is warm enough. The genus Callirhoe was named after the daughter of Scamander, a Grecian fabulous character.

TARDES.—"R. P." is much obliged to Mr. Hall. Nothing is further from his intention than controversy; but the mystery is still unexplained, as he knows the signs and the sight of things too well to be deceived in anything respecting them. He would know by the appearance of a leaf whether thrips had been there or not. Thus far it should be stated that the plants that suffered in these two lights were from old seeds, but a plant from fresher seed, and the same as flourished in frames, &c., was affected in the same way. There may be something in the glass, but nothing else has suffered except Melons; and the same thing has happened for several years as respects the first crop. "R. P." believes that getting the foliage dry in certain circumstances as those referred to is of first consequence.

LARGE FRAGRANT ROSE (A Lady in Cheshire).—"I recommend Charles Lechvre. It is red, has the desired qualities, and can be pot-grown. It has no equal. Senateur Vaisse and Madame Victor Verrier are also good. As a pink rose Jules Margottin has no equal. Anna Alexici is also large and fine, and good for your purpose. Of a rose-colour Baronne Prevost would suit. John Hopper rose with crimsonish centre, is splendid. These all would supply what you require—namely, the earliest, largest flowering, and most fragrant roses to be grown in a pot to be placed in a hall when in flower." They are all fine-constituted, free and abundant bloomers. I advise you to have also Prince Camille de Rohan, dark velvety maroon or purple—the largest, finest, and handsomest dark rose known.—W. F. RADCLIFFE."

NAMES OF PLANTS (Richard Graves).—Your plant is Clitoria ternatea, and has been long in the country.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending June 16th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

HANTS AND BERKS POULTRY SHOW.

ALTHOUGH our province is with poultry, it may not be out of place to take some notice of these events with which it is intimately connected; and above all to express our satisfaction if we find our favourite subject following the track in which we have always wished to find it. Poultry and agriculture would seem to be intimately connected, inasmuch as the occupier of land has facilities denied to others. If, then, those who have the disadvantages of limited space, and the necessity of buying every article of consumption, can find it a self-supporting hobby, those who have food produced at the lowest cost, and the space gratis that others would be content to acquire at a considerable cost, should find a large profit. Poultry, at last, is urging its claims on the public at large; and while we repeat that which we have often written—that poultry will never become an article of general consumption, we may say that the hundreds, ay, thousands of pounds sent abroad might with a little painstaking be kept at home. When we say it will never be an article of general consumption, we would not be thought to admit for a moment that there will not be always good sale for all that can be produced. Eggs are things of general use, and these can be produced by the farmer at a nominal cost. The age of pooh-poohing these things is passed away, and the increase of

the Show with which we have to do will prove it. From the small exhibition of a few pens, some five or six years ago, it is now a considerable exhibition, numbering 226 pens of choice birds from all parts of the country. This would prove nothing, as the exhibitors might be amateurs from many towns; but the fact in which the birds were located was a chief point of attraction, and the conversation that could be heard through the canvas walls before it was opened was new. It showed that poultry was rising, and taking as it deserves to do, its place besides the quadruped denizen of the farmyard.

Copying a powerful neighbour, the Society with which this Show is connected has become peripatetic, visiting the chief towns in detail. This year the Show was held at Winchester, and with the remark that there was an excellent show of cattle, a large exhibition of implements: that the band of the 60th Rifles lent its attractions, and that the weather brought so many spectators that the meeting was a success and a pleasure, we will pass to the consideration of that which is our especial duty.

The day is gone and past when the success of one was rendered easy by the mistakes or shortcomings of the others. All understand their work, and those who were successful were so by force of merit.

The Dorking exhibitors showed many of our best names. It will hardly be marvelled at, that the first prize went to Surrey, taken by Mrs. Norris, the second to Col. Lane. The list we publish will show the commended, they were deservedly numerous.

Twenty good pens competed for *Game* honours, and we have seen many worse classes at very large shows. All colours were well repre-

sented and all countries, proof of which may be seen by the fact the first prize went to Warwick, the second to Dublin.

The *Game* classes were excellent. Here, again, there were no errors in judgment to make decisions easy. The Black Reds held their own well against the Brown Reds, and the merits of the Duckwings as *Game* birds was almost equalled by their merits as birds of feather.

The *Polands* were very good, but brought only six entries. The *Spanish* shown were worthy of any exhibition. The same may be said of the Golden *Hamburghs*, Pencilled and Spangled, but the Silvers hardly maintained their reputation.

There were twenty-two pens of *Brahma Pootras*, twelve Light and ten Dark, showing most of our leading exhibitors in both classes. The names, however, that mostly stand in the front rank did not on this occasion.

Fifteen pens of excellent *Game Bantams*. Here we would warn exhibitors these birds must not drop their wings like *Sprights*. Two cocks shown would seem to have been chosen for this bad quality. They were otherwise excellent birds. There were fifteen pens of "Variations" Bantams, some of them beautiful specimens. The first-prize pen were highly meritorious.

The French fowls were good. The *La Flèche* are losing ground—one pen only was shown. The *Houdans* were not so good as the *Crève-Cœurs*.

There were all sorts of curiosities and many very pretty "oddities" in the class for Any variety. The *Ducks* were excellent. There was also an excellent show of *Pigeons* and *Rabbits*.

DORINGS.—First, Mrs. E. G. Norris, Hatchford Parsonage, Cobham, Surrey. Second, Lieut-Col. Lane, Bracknell. Highly Commended, Lieut-Col. Lane; Miss J. Millward, Newton, St. Lee, Bristol; D. C. Campbell, M.D., Brentwood.

COCHINS.—First, Rev. S. C. Hamerton, Warwick. Second, C. F. Staunton, Clonsalkin, Dublin. Highly Commended, Mrs. Christie, Glyndelourne; W. W. Pyne, Lancing; S. A. Wyllie, East Mousley; H. Yardley, Birmingham. Commended, F. G. Stebbing, Fleet, Winchfield; E. W. Boys, Winchester.

GAME (Black-breasted and other Reds).—First, W. W. Pyne. Second, H. Lee, Appledrambe, Isle of Wight. Highly Commended, H. C. Dear, North Stoneham Park, Southampton; Rev. G. S. Cruwys, Tiverton. Commended, T. R. Hulbert, Old Alresford; W. H. Stagg, Netheravon; Rev. G. S. Cruwys; S. Matthews.

GAME (Any other variety).—First, S. Matthew, Stowmarket. Second, Miss Hales, Canterbury. Highly Commended, Rev. G. S. Cruwys.

POLANDS.—First, Mrs. Pettatt, Ashe Rectory. Second, T. P. Edwards, Lyndhurst. Highly Commended, Mrs. Pettatt; D. Mutton, Brighton. Commended, Mrs. Pettatt.

SPANISH.—First and Second, F. James, Peckham Rye. Highly Commended, Rev. J. De L. Simmonds, Chilcomb Rectory.

HAMBURGERS (Gold-pencilled).—First and Second, F. Pittis, jun. Highly Commended, Miss Hales.

HAMBURGERS (Silver-pencilled).—First, H. Pickles, jun., Earby, Skipton. Second, F. Pittis, jun.

HAMBURGERS (Gold-spangled).—First, H. Pickles, jun. Second, T. Walker, jun., Denton, Manchester. Highly Commended, H. Lee.

HAMBURGERS (Silver-spangled).—First, H. Pickles, jun. Second, H. Lee.

BRAMA POOTRA (Light).—First, H. Dowsett, Pleshey, Chelmsford. Second, H. M. Maynard, Holmwood, Ryde. Highly Commended, J. Pares, Postford, Guildford. Commended, Miss Harvey, Sarisbury, Southampton.

BRAMA POOTRA (Dark).—First, J. H. Croft, Metropolitan Cattle Market, London. Second, J. K. Fowler, Aylesbury. Highly Commended, Lieut-Col. Lane. Commended, S. A. Wyllie, East Mousley.

GAME BANTAMS.—First and Second, F. Pittis, jun. Highly Commended, G. Johnson, Farnham, Surrey; Rev. G. Rayner, Tonbridge, Kent.

BANTAMS (Any other variety).—First, Miss Hales. Second, Messrs. Lonkin & Tuckey, Bristol. Highly Commended, H. M. Maynard; Capt. E. J. Baker; Rev. G. S. Cruwys; Messrs. S. & R. Ashton, Nottram; Mrs. Pettatt. Commended, Mrs. St. John.

FRENCH.—First and Third, Col. Stuart Wortley, Grove End Road, London. Second, J. K. Fowler (Crève-Cœurs). Highly Commended, J. Burghope, jun., Stroud (Crève-Cœurs). Commended, Mrs. St. John; H. M. Maynard (Houdans).

ANY VARIETY NOT BEFORE MENTIONED.—First, J. Binton, Hinton (Malays). Second, Col. Stuart Wortley (Fringed Japanese). Third, Mrs. St. John. Highly Commended, F. Pittis, jun. Commended, J. Pares (Silkies); Mrs. Morant.

DUCKS.—First, J. K. Fowler. Second, Mrs. E. G. Norris. Highly Commended, F. Pittis, jun.; Mrs. Morant. Commended, Mrs. Morant; J. K. Fowler.

PIGEONS.

CARRIERS.—First, H. M. Maynard. Second, H. Yardley. Highly Commended, J. Lufkin, Farnham.

TUMBLERS.—First, J. Lufkin. Second, H. Yardley. Highly Commended, G. Hill, Winchester; E. Shearn, Chelmsford.

FANTAILS.—First, H. M. Maynard. Second, H. Yardley. Highly Commended, Miss J. Millward; H. Yardley; W. S. Loder, Bath.

TRUMPETERS.—First, E. Shearn. Second, H. Yardley. Highly Commended, A. P. Maurice; G. Hill. Commended, H. Yardley.

MAGPIES.—First, H. Yardley. Second, F. Pittis, jun.

ANY VARIETY NOT BEFORE MENTIONED.—First, S. Loder. Second, J. Lufkin. Highly Commended, H. Yardley; W. S. Loder; H. Yardley; F. Pittis, jun.

RABBITS.

LONGEST EARS.—First, G. Hill. Second, G. Jones. Commended, C. Gravel, jun., Thorne; F. James; H. Yardley.

FOREIGN.—First, Mrs. Churcher, Stratton, Mitcheldever. Second, H. Yardley.

VARIETY, TO INCLUDE ALL POINTS.—First, G. Jones. Second, C. Gravel, jun. Highly Commended, G. Hill; A. E. Smith, Gosport. Commended, Master E. J. Bennett, Chilmark, Salisbury.

Mr. Bailly was the Judge.

POULTRY CULTURE.

At a recent meeting of the Food Committee of the Society of Arts, B. Shaw, Esq., in the chair, Mr. George Manning, of Springfield, attended, and gave information respecting Poultry Culture as follows:—

Mr. Manning said.—In looking for new sources and for the farther development of the old means of animal food, I cannot but think that poultry claims our attention before many others, as having once formed an important part of our meat supply, as being simple and inexpensive in culture, and everywhere ready to hand. Of late years, however, poultry has fallen into neglect; and this kind of meat can now be procured at such prices only as to render it an expensive luxury rather than a reasonable portion of daily food. The farmyard seems to be the proper home of the avian order of birds; yet it is here that the neglect is most evident, whilst farmers, for the most part, deny the usefulness of this portion of stock, and tolerate it only from habit. It is not only the farmer, however, who raises objections to this kind of food. The consumer has certain prejudices. On the part of the farmer it is said:—

1. That poultry stock does not pay.
2. That even if it did pay it is too unimportant to engage his attention.
3. That it damages the stock yard.
4. That it is injurious to the crops.

On the part of the consumer it is urged:—

1. That the retail price of poultry is such as to place it out of the list of daily foods.

2. That, even if it can be produced at reasonable prices, it is a poor substitute for butchers' meat, and does not contain sufficient animal nourishment.

If poultry-keeping does not pay, and under existing circumstances in the majority of cases it probably does not, the reasons are to be found in the following facts:—

1. That no attention is paid to the choice and management of stock.
2. That food is irregularly and wastefully administered to it.
3. That no regard is had to the roosting, and particularly to the laying, places of hens.
4. That the demand is restricted by the market system.
5. That farmers' wives have ceased to be henwives.

With regard to the choice and management of stock in poultry, we find on farms generally, mongrel-bred birds, which, from continued in-breeding, have deteriorated in size and stamina. The barndoor fowl of the olden time has changed, particularly within the last few years, becoming continually less useful for food. It is true that the barndoor fowl was always a mongrel; but when farmyards were the nurseries of fighting cocks, where landlords, by covenant inserted in the leases, required the tenants to "walk" a Game cock, or number of cockerels, and tenant farmers bred birds for the pit on their own account, there was a continued infusion of new and vigorous blood into the progeny of the hens that stocked the yard. That custom has happily nearly passed away. The deterioration, however, begun by the loss of these high-bred cock birds, was completed shortly after the Cochinchina mania, when by the introduction of cock birds of this variety (valuable as the hen birds are for certain purposes), a race of spare-breasted, leggy birds has been the result, wanting the chief merits of a table fowl. Again, when the flail and a careless system of farming made the barn door a golden feeding ground, chickens had opportunities of growth which they now have not, and which must be supplied to them more economically and judiciously by hand if rearing poultry is to be profitable. This, plan, however, has been neglected, for poultry, unlike other farm stock, has not only not advanced, but has gone back in value, and consequently in estimation. The average weight of barndoor fowls sold from farmyards is 3½ lbs. From this must be deducted 3 ozs. for feathers and 12 ozs. for offal before they become food. The Game cock, as bred for the pit, rarely exceeded 4½ lbs.; but by crossing with the Malay they may be brought to 6 lbs. or 7 lbs. in weight. Dorkings, when not inbred, but well and carefully fed as chickens, will reach to 7½ lbs. as pullets, and to 9 lbs. as cockerels; higher weights, such as 10 lbs. for hens, and 12 lbs. for cocks, can be obtained, but these are exceptional. Dorkings, however, are not suited for cold clays and damp soils. Of food birds, besides Dorkings, the Game and the large Surrey and Sussex fowls (which last always command a high price), there are the *Brahma Pootra* fowl and the *Houdan*, or French Dorking, well adapted for use. Of these the Dorking and Surrey fowls are beyond all question the best for the table, in delicacy and weight of flesh; the Game the most savoury, although deficient in size; the *Brahma Pootra* not so delicate in flavour as the others, but hardy, weighty, and easily fattened; the *Houdan* having the good without the bad qualities of the Dorking—precocious and small-boned, being non-sitters, and almost uninterrupted layers of large eggs. The *Brahma Pootra* seems to be a useful stock on which to build other varieties. Of these, the cross with the Dorking is most strongly recommended; and a cross with the *Houdan* produces table chickens of a fine size. At the last Chelmsford and Essex Poultry Show, the birds which took the first and second prizes for dual poultry, trussed as by poulters, but not drawn, were, the one 13 lbs. 12 ozs., the other, 13 lbs. 10 ozs., the pair at five months old. They were the direct offspring of a *Brahma Pootra* cock bird and Dorking hens. For stock it would be a better plan to put a Dorking cock with *Brahma Pootra* hens, and the pullets of this union with Dorking cocks in no way related to the ancestors of the pullets.

Very hardy and weighty table birds may thus be produced. By answers to inquiries, and by reference to the books of a farm including the last six years, I find that the average price paid by bidders for barn-door fowls of the average weights first mentioned is 2s. for coop-fed, and 1s. 8d. for yard-fed birds. The cost of feeding and rearing the prize birds at Chelmsford was probably very little, if at all, more than that of raising the others. With regard to feeding, our system of leaving chickens to shift for themselves until such time as they are ready or wanted for the coop is all wrong. No attempt at after-tattening will increase frame if the feeding of infancy has been disregarded. Again, the indiscriminate emptying of apronfuls or sievefuls of grain in a heap on the ground, whilst it serves to gorge the powerful, leaves chickens and weaker birds to starve, picking up here and there a grain, whilst sparrows and small birds have a large share in the feast. I see that Mr. Mechi has published the results of an experiment in the cost of feeding a single hen, shut up and without access to any food but that which was given by hand. The result shows that 5 lbs. of barley at the average of 1d. per lb. (or 10s. the quarter), will make 1 lb. live weight of poultry food, worth 9d. per lb. I say it is quite practicable to feed poultry more cheaply, and consequently to sell them cheaper than shown by this method—that is supposing them to be at large; but I am sure Mr. Mechi will pardon me for saying that I think this statement of feeding in confinement is rather low, a circumstance which may arise from the fact that the bird pined at first. I have tried the same experiment with two pens of birds, consisting of a cock and two hens, confined for a long time to separate but very small wired pens. I tried it in March last year, and in the month just ended, and I found that my birds consumed about 3½ pints to his 2½ pints in the week; but then I dare say the barley I used was of foreign growth, and of much lighter bulk. Birds having a free run would cost very considerably less. I must not occupy your valuable time with the details of what is necessary for the housing of birds and, for their places of laying and incubation. It will be enough to say that they should be, what they are seldom in farmyards—namely, cleanly, convenient, and attractive.

Captain Grant: Do you think a hen's nest should be high or low?

Mr. Manning: It should be on the ground, if there is no danger from rats, for laying and also for hatching; and the roosts should be low, particularly when they are heavy birds. I believe the sore and injured feet, which are not unusual in large poultry, are often caused by their jumping down almost perpendicularly from a high roost. Fowls will always choose the highest perch, probably because it is the warmest, and when this is in a large open shed, as a cart lodge, they have room for some length of flight before reaching the ground, but in a small poultry house they come down very heavily. If the perches are arranged in steps one above the other they will jump them one at a time until they reach the highest, but they will not come down that way. I do not approve of artificially warming the fowl house; it should be well built, and brick is better than wood, being warmer, and more easily cleaned; but I think if the introduction of hot-air pipes is allowed it must produce such a warmth that on going out into the cold air the fowls are apt to get chilled, and to have an attack of the "roup."

Mr. Hoskyns: I have a small fine passing through my fowl house, and I find that it tends to improve the regularity of laying, and does not produce any ill effects.

Mr. Manning: It may be useful if very judiciously employed, but I am always afraid of it. It would depend, too, on the breed; the Brahma Pootra and Cochins are very hardy, whilst the Dorking is very delicate. On the point that the demand for poultry is restricted by the market system, I would call attention to the fact that poultry produce stands at a costly rate to the consumer, and at a poorly remunerative one to the producer, by reason of the irresponsible middle men through whose hands it passes before it reaches the retail seller. Again, in its perishable nature the producer is liable to much loss in a dull or a glutted market. In this matter I would venture to suggest the establishment in London, and the great towns of the United Kingdom, of wholesale markets, either apart from or in connection with the meat markets, subject to police and other regulations, to have sales by auction, so that no part of the consignment need be returned to the producer, or destroyed as unfit for food; to extend the same principles of markets and sales to other towns in the kingdom on their market days. One of the reasons already given for the neglect of poultry stock was, that farmers' wives have ceased to be henwives. Perhaps in the altered state of society it is unavoidable. It is, however, to be regretted. But poultry-growing, as a part of farm stock, and an item of our daily food, will need masters rather than henwives. I mean that if it were carried on by the husband as a regular part of his business, he would feed his poultry the same as he does his horses and his stock; but when it is left to the wife, there is often a complaint of the quantity of food required for the poultry, and a little sly barn robbery the result of waste.

Mr. C. W. Hoskyns: But part of the economy of poultry-keeping consists in the fact that the wife is able to attend to it.

Mr. Manning: Oh, yes; and it should be so. There is nothing in the management of poultry which goes beyond an ordinary woman's capabilities; the only thing is to see that they have food enough without waste, and that chickens are carefully reared.

Mr. Hoskyns: Are there not many oleaginous seeds which might be used with advantage in feeding?

Mr. Manning: Yes; I have tried bran or buckwheat, which is very good, and so is Indian corn. Cheapen a necessary of life, and a demand follows instantly; this is a maxim illustrated every day. Simplify the market system and improve the means of production; you will then remove the consumer's first objection—viz., price. The second objection as to nutriment is answered by the fact that, as a flesh-forming food, poultry is more nutritious than beef. It is only inferior to beef as being less fattening, for it contains a little less water, a fraction per cent. less albuminous matter, and a greater proportion of salts. To the remaining objections urged by the farmers, that poultry damage the stack yard, I have little hesitation in saying that this is a mistake where stacks are set upon frames, and birds regularly and judiciously fed. The other—namely, that poultry damage the crops, will, I think, receive a conclusive and practical answer from Mr. Mechi. Mr. Mechi keeps three hundred head of poultry, which have free access to the fields near the homesteads, and he buds that they do more good than harm. With regard to the system of sales by auction, this plan has already been adopted by Messrs. Broome & Co., meat and poultry salesmen in Newgate Market. Their manager, Mr. Brooke, has been in Normandy, and the other poultry districts of France, to ascertain the French methods of feeding, and of poultry management generally, which appear to be more systematic and economical than our own. Messrs. Broome have kindly consented that their manager should attend before you, if desired, to give any information that may be of value. Taken in connection with the statements of the weight and the cost of rearing barn-door fowls, it may be useful to place side by side the prices quoted in Newgate and Leadenhall Markets at two periods of the year, which will represent plenty and scarcity of produce.

Sept. 21st, 1867. March 27th, 1868.

Surrey fowls, per couple	10s. to 12s.	10s. to 12s.
" chickens "	5s. 6d. to 7s.	6s. to 8s.
Barn-door fowls "	4s. 6d. to 6s.	5s. to 7s.

Mr. Mechi is now getting 7s. 6d. a-pair wholesale for chickens. It is impossible at present to procure any reliable information with regard to the home produce and the consumption of birds and eggs in this country. It has been variously and vaguely estimated. The story of our imports, however, tells a startling tale:—

In 1849 we imported	98,000,000 of eggs.
In 1866 "	488,878,880 "
In 1867 "	397,984,520 "

The cause of this reduction in last year's imports I am not prepared to give. The price of English eggs per hundred in Newgate and Leadenhall Markets varies from 6s. 6d. to 13s. ordinarily in the season: the difference between the prices of English and French eggs being, for the most part, 1s. per hundred. The custom-house return of eggs and poultry imported in 1866 (the totals, except in the case of eggs, not being yet made for 1867), gives the following details:—

Eggs.		Great hundred.
Imported from		
Hamburg	16,630	151,733
Belgium	3,359,302	80,055
France	31,840	17,764
Channel Islands		
Other parts		
Hundreds	3,657,324	
Long hundred	120	
Eggs	488,878,880	
POULTRY.		Value.
Imported from		
Holland	£16,815	
Belgium	97,082	
France	58,210	
Other parts	4,564	
	£174,971	

Value of eggs (at 6s. 6d. per 120), £1,188,630; total value of eggs and poultry imported in 1866, £1,263,601. If the foreigner can undersell us in our own markets in eggs, and can send a very large amount in value of poultry into this country; if our own eggs, in spite of this competition, maintain invariably a higher price, it is beyond question that there is—at all events, in our own production—a demand unsatisfied, and a profitable source of food neglected. I have made several inquiries into the matter of artificial hatching, and I am not satisfied with the results. The great difficulty is in rearing the chickens when they are hatched. We have no evidence to show whether the cultivation of poultry is increasing; there are no returns of the quantity sent into the market, and it is impossible to get accurate information from the farmers to a sufficient extent to form an opinion. If you took the railway returns you would probably be unable to separate the home-bred from the foreign poultry.

The Chairman: Before proceeding any further with the discussion I will read a letter which we have received from Mr. Mechi, which is as follows:—

"Tiptree Hall, near Kelvedon, Essex,
"March 21st, 1868.

"MY DEAR MR. FOSTER.—I am not often in town, but hope to be so in a week or ten days, and will endeavour to meet the Committee. My experience teaches me, first, that there is an abundant demand for poultry in our markets, even at the present extravagant prices; that while poultry sells at fully 9d. per lb. live weight, the best beef and

mutton only at 4d. per lb. live weight (5s. per stone of 8 lbs. nett dead weight); that it costs no more to produce 1 lb. of poultry than 1 lb. of meat; that poultry are the farmers' best friends, consuming no seed of insects, and utilising and economising all waste grain; that they should have free access to pasture and to our other fields near the homestead; that care should be taken as to their breeds, as in sheep, bullocks, and pigs; that first crosses, having regard to the demands in the market, are advantages; that the manure from poultry is of first-rate quality. My poultry (about three hundred) have free access to my corn fields at almost every period of the year. Of course, poultry, like sheep, bullocks, or pigs, must be well and properly fed if they are to be well developed in size and condition. I do not know that I could say more than this to the Committee.

"P. Le Neve Foster, Esq."

"Yours faithfully,"

"J. J. MECH."

Mr. Chester: There is no doubt that in France there are a great many more eggs and poultry produced than in England, compared with the population. I should like to know what is the reason of that; and whether we could, by putting out any practical suggestions, increase the supply. We shall not see the price reduced or the distribution improved until the number produced is increased.

Mr. Wilson: I think the cottier system, which is so prevalent in France, is very favourable to the production of poultry. Have you ever tried the experiment, which, I believe, has been tried in France, of having a moveable poultry house, which can be taken from field to field?

Mr. Manning: I have not tried it, but I should think it would be very successful. The only objection is that the poultry are left unprotected. My attention has been principally directed to poultry kept in small places, and I don't think it can be carried on profitably in that way, because all the food must be purchased; you must then sell at fancy prices. If a considerable number are kept in a confined place, there must be some arrangement for changing the soil, which, in most cases, would occasion a difficulty. I kept three Cochins-China fowls for about three months in a small space about 1 ft. by 1 ft., with a little bed behind for roosting; but then I had the droppings continually removed and the soil constantly dug up. The prices paid to the producer by the higgler are 2s. for a coopful, or 1s. 6d. for a running fowl, weighing on an average 3½ lbs. I see no reason why poultry should not be sold by weight; I think it would be a very great improvement if all provisions were required by law to be sold by weight. The size and weight of the eggs from a Spanish and a Hamburgh fowl are very different, but they are all sold at so many for a shilling; and a retail dealer told me that he allowed a good customer to pick out which he liked. I have used Indian corn for fowls, and it answers very well, but just at present it is very dear. You cannot always keep to the same kind of food, whatever it is. In Sussex they use a good deal of bruised oats; I have used a mixture of bruised oats, rice, and toppings, with success. I doubt the advantage of feeding fowls with meat; the kind of flesh which the fowl picks up naturally is very different to anything we could give them. I have seen the reports of the large poultry farm in France, and I know them to be wholly untrue. I am certain that no experiments have been made on a large scale in this country to feed poultry on horseflesh mixed with farinaceous food, but I cannot say what has been done abroad. Graves and other animal food have been given to force the laying of hens, but I believe the tendency is to wear out the hen very quickly.

Mr. Wilson: Would it not answer to do that? To get all the eggs you can, and then fatten the fowl for table?

Mr. Manning: Perhaps it might. An old hen may be made to eat very well by boiling it first, and then roasting it. I keep breeding fowls about three years, then I sell or eat them. The eggs are not so good for breeding from the first year as the second and third; in the fourth year they begin to fail, according to the constitution of the bird. The best breed for cold clay soils is the Brahma Pootra or the French sort, the Houdan. I think a cross between the Brahma Pootra and the Dorking gives the most useful bird for farmyard purposes. The Brahma has a good deal of the Cochins-China in it; it lacks breast a little, but not so much as the Cochins; and when crossed with the Dorking it produces a very fine bird, with all the hardihood of the Brahma Pootra and the meat properties of the Dorking. If the soil is good, no bird would answer better for a cottage than the Dorking. Lime must be supplied, of course, if it is not naturally present in the soil, where birds are in confinement. I have had no experience with Ducks, Geese, or Turkeys. I think poultry-keeping would be carried on more successfully on a large scale than by individual cottagers.

Mr. Wilson: Is there not a great tendency to epidemics amongst poultry kept together in large numbers?

Mr. Manning: I think Mr. Mechi would answer that by saying, not if the yards are kept well supplied with lime and salt. If the fowls were free to run in the fields it would be a long time, indeed, before the ground became tainted. It would be almost an impossibility.

Mr. Wilson: Should you feel inclined to go into the speculation to the extent of thousands?

Mr. Manning: I think Mr. Mechi could answer that question better than I can. He has three hundred. I think the great difficulty with small farmers would be in finding a good and ready market. The large breeder has a salesman in town, to whom he sends his produce; but the cottager and small farmer might not have those opportunities; they must depend on the middleman or higgler. I do not think it would answer for the small farmer or cottager to breed fowls for his own use.

Mr. Wilson: Would not a Goose or a Duck fatten for itself until it was time to fatten it?

Mr. Manning: I do not know about that; but the farmer would not like to see the cottagers' Geese wandering over his fields.

Mr. Chester: Do you think it better to adhere to a pure breed, a specific sort, or to let all sorts run together, and trust to nature to produce the best result?

Mr. Manning: On a light soil I should prefer a pure Dorking, taking care not to inbreed; if it were not a light soil I would have a cross between the Brahma Pootra and the Dorking; in all cases I would have the Dorking, either pure or crossed. If you require only eggs, you may dispense with the cock bird altogether; for breeding you should not have more than eight hens to a cock, and if breeding for exhibition or fancy purposes the number should be still further reduced. I don't think the eggs are quite so palatable where the hens run alone. I think it would be well if in poultry exhibitions there were some class for farmyard poultry, and if, as has been done at Crystal Palace, dead poultry were included. The Hamburghs, Spanish, and French varieties produce most eggs, but they never sit. I believe the most delicate flavoured bird of any for the table is the Dorking. I can quite imagine that there may be an impression in France that the Houdan is superior, but I should not like that to a national feeling. The Houdan produces very early chicks; but the earliest are the Cochins; they are very hardy and can be reared even in the snow. I cannot say exactly why cheap poultry are always bad, but a fowl that has been fattened will keep longer than one that has not. I have not experimentally on artificial hatching, and speak only from observation and information on that question. The difficulty is in rearing the chickens. I believe Mr. Schrodler, at Rickmansworth, is trying it on a large scale. Colonel Stuart Wortley has invented a new incubator. The great difficulty is in rearing chickens from them fit for the market. This is the opinion of the salesmen.

PACKING EGGS.

A number of numerous modes of packing eggs are advocated from time to time in your Journal, I have felt reluctant to state my individual opinion; but as "CONSTANT READER" in the number of the 4th inst. has been the first to advocate sawdust, it may be useful to add my practice to his experience. They perfectly coincide.

During the last three years I have had about 600 dozen of eggs forwarded to places far and near, each egg rolled in paper, and packed on end in sawdust; a layer of soft hay lining the top, bottom, and sides of the basket, which is tightly fastened with pliable wire. Their exemption from breakage when packed in this way is marvellous, and I cannot learn that their firmness is in the least impaired by it. Moss and cotton are difficult to manage, and expensive; rolls of hay are clumsy; and, as your correspondent avers, sawdust is cheap, cleanly, and comestible.—J. C. COOPER.

ANTICIPATIONS OF PIGEON FANCIERS— ANTWERPS—DRAGOONS.

I have been an enthusiastic breeder of Pigeons for the last seventeen years, principally abroad, and I am happily now acquainted with many enthusiasts in this country, who justly value your Journal quite as much as I do. Since the Pouter controversy began, I and those I allude to anticipated great revolutions and important reforms in regard to our shows, which should be the principal point of all interested; and I beg here to ask, What has become of the amalgamation of the two great metropolitan Societies? I, and many more, bailed with the greatest pleasure the union, and expected most anxiously every week to receive "our Journal," and satisfy our expectations.

I consider the first and most important point to us all, is the selection of judges for our shows. I suggest, therefore, that the great metropolitan Society will take the initiative, and I am positive that every society in England, and one of the first of which I have the honour to be a member, will be ready to co-operate in memorialising the committees of the principal shows to discontinue selecting judges from dealers. That done (and it will be our fault if left undone), the greatest evil has passed.

Then, I suggest, with all due respect to the metropolitan impartial judges, that local judges should also be selected, and I believe there are, or must be, many in this country, so that breeders will have the opportunity of knowing the opinion of several, and not only the few privileged principal metropolitan gentlemen; and my reason for suggesting this is, the oft-heard conversation between us, "So-and-so will judge, we must show such and such a colour, such a style, eye, &c."

Then, again, "They (expecting the same gentlemen), have given the first prize to such a colour in such a class last year.

but to another colour this year. They will give the turn next to the one which had the prize two years ago."

However singular these remarks between fanciers may be to those unacquainted with such controversies, they are based on the experience of years. On a certain class one of the Judges was heard to say, "We have given that variety plenty of prizes, we must give the chance to others for encouragement." Another great Judge has it as his motto, that a pair of birds to obtain a prize, "must be as nearly alike as two pins;" and I often wonder if he is aware that the exhibitors finding this to be his principle of judging, have invariably presented for his judgment, in a certain class, two cock birds, and I know those who obtained the prize in this way repeatedly, for it is impossible in certain classes to match the birds so exactly in colour as to appear "as nearly alike as two pins." Now, is this judging? What matters it how many prizes a variety has had, as long as it is worthy of the honour? If a judge who had not judged the same show in the year previous was to officiate, that consideration will disappear, and things will be more fair to all.

I shall be most happy to contribute my experience on the different varieties which I have kept, my mode of keeping them, and my treatment of some of their diseases which I have most effectually cured.

Just as I wrote the last sentence, I received "our Journal," and I perceive, in "Notes on Fancy Pigeons," by "WILTSHIRE RECTOR," some most astounding revelations in respect to Dragons and Antwerps. According to "WILTSHIRE RECTOR'S" views all fanciers possessing Blue Carriers, must in future call them Dragons, however "heavy" they may be, and all who possess Yellow Dragons must in future call them Horsemen. I know a great Dragon breeder who considers a good pair of Yellows above all other colours, and this we are sufficiently convinced is the view of the principal Judges, as when there is a good pair of Yellows they are always the first.

And now a word about Antwerps—the racehorses of Belgium. I have promised "our Journal" to a friend in Brussels, who visited me last week, and I wonder what he will exclaim when he reads that his seven-hundred-miles flying birds, which won for him four prizes last year in the national race, and hopes to be successful again this year in the great race from near Bordeaux to Brussels, "not being birds of colour, or points, are useless!" Our foreign friends have proved to us repeatedly, that there is not a Dragon or Horseman in England which can compete with the Smerl, which when bred for exhibition is capable of bearing comparison in every respect, and will be found even superior to either, simply because it beats them both in the only property they were intended for, as I consider, in colour. We see Blue Antwerps quite as good as the best Blue Dragons; but there cannot be any of the latter in colour as fine as a good Dun Antwerp, grey-headed, purple-necked and breasted, and well barred, or a good Blue Chequered, or Red Chequered, with the carriage of a Dragon, and a head as intelligent and symmetrical as a Barb's, and capable of performing a longer journey till old age puts a stop to this great property.

I believe "WILTSHIRE RECTOR" makes a mistake in supposing the Pigeon of the Dragon tribe, which was reported to have won the match, to be a Dragon of his recommendation, I am almost certain it must have been an Antwerp (if it was anything like a match), as we all know that Antwerps are considered of the Dragon tribe, but much more distinct, as whatever colour they may be, though we have four recognised colours, you cannot call them anything else, while many authorities on Pigeons allude to the Dragon as an inferior Carrier.

I trust "WILTSHIRE RECTOR'S" remarks will not in the least discourage any Antwerp fancier, for they can well afford in answer to say, We rather breed Antwerps which are not liable to be lost easily, most likely to return home two or three years after they have been disposed of, looking rather venerable, and almost unknown, and ready to breed, and rear two, three, and even four young ones of other delicate varieties—in fact, to do what no other variety can do in this respect, than to try to breed his grand Carriers, Dragons, or Horsemen, the first of which has become disfigured, as a good Carrier was not, in my opinion, intended to be a bird which when three years old is not able to pick up the grain he is to sustain life with, unless it is supplied in a trough; or the second, which is liable to changing his name by his colour.—A FOREIGNER.

HAVING kept Pigeons about twelve years, and still with increasing pleasure have them about me, I always feel deeply

interested in the perusal of the various opinions of the writers in your Journal, and I was particularly so in those in the number for June 4th.

Labouring under the disadvantage of very indifferent accommodation for giving my birds their liberty to fly, I have given up many varieties which I most admire, and have kept principally to Antwerps, only having besides one pair of Dragons; and having given much time and attention to their requirements and improvement, I have acquired a liking for the former, which brooks not the sweeping condemnation that "for exhibition they, as not being birds of colour or points, are useless."

First, there are four distinct colours approved by our most eminent judges, and to which prizes have been awarded, colour too often having taken the precedence of points, which this breed certainly possesses rather to excess than otherwise, as proved by the fact that scarcely two judges agree as to what character of bird should take the first rank. Having been guided by their decisions, I find myself in possession of several distinct varieties, with any of which I should not feel afraid of entering the lists of competition with other Antwerp fanciers, as they each carry points, though of slight variation in the whole sufficient to recommend them to notice, if not to admiration.

Now, the question naturally arises, How is it that more than one variety should be maintained by a breeder for competition in one class? Simply because there is wanting a "Standard of Merit," and as such can only be effectually agreed upon by judges and extensive breeders, there should be no time lost in carrying into practice to the fullest extent the suggestion of Mr. Fulton in respect to the selection of judges. Hitherto in this respect Antwerps have been sadly neglected, the consequence being that this large class has been made up of birds varying from those finely-developed specimens, many of which appear annually at Birmingham and other Shows, and some little better than Blue Rocks.

I believe the travelling properties of both Antwerps and Dragons are, or may be good, but the best strain of "racers" I know are Antwerps, and they are also handsome birds. Distance from home about 130 miles.

That one pair of birds will produce young of different colours is a fact often verified, but is not confined to Antwerps, as I need not remind most breeders of fancy Pigeons, presuming that all have experienced the truth that the gems for exhibition for colour, as well as other points, are the exception, not the rule.

Will Mr. Fulton kindly name those he would like to see as judges at coming shows?—J. I. B.

HIVING BEES.

WHEN bees are allowed to swarm naturally, everything should be in readiness before the swarming season arrives, so that when swarms come off there may be no confusion or difficulty in hiving. Hives should be kept cool, and if old they should be well cleaned. If a swarm is seen issuing from a hive, do not get in a "flurry," but keep cool. Do not be so foolish as to blow horns, ring bells, and scare your bees to the woods; but stand quietly and watch their movements, and nineteen times out of twenty they will cluster all right. As soon as they have settled prepare to hive them, an operation which may be successfully done, and without the least difficulty, as follows:—

First, bring a dish of cold water, and with the hand or a whisk of grass sprinkle the cluster well. This will make them perfectly quiet and easy to handle. Bring out a table, or, if that is not convenient, spread a cloth or boards upon the ground; and if they are to be hived into a common box or straw hive, set it upon the table or place prepared for it, raise up one side an inch or more, and put under a stone or chip to hold it. Then shake your bees into a pan, ba-ket, pail, or any dish that will hold them, and turn them down near the hive, and they will at once commence to enter. If it is desirable to have them enter faster than they are naturally inclined to do, take a wing and gently wing them in. As soon as all or nearly all are in, the hive should be carried to its stand, and well shaded if the sun is shining. New hives or newly painted hives should be shaded for several days, as bees cannot stay in an overheated hive. If the bees cluster upon a limb, from which it would be difficult to shake them, the limb may be cut off with a saw and laid near the hive; the bees will soon leave and enter. Sometimes bees will cluster upon the body of a

tree, when it is more difficult to get them off without irritating them. They should be well sprinkled, and very carefully brushed off with a wing or quill feather into a dish, and carried to the hive as before stated. An inexperienced person or novice should in this case wear a bee-protector. It will give them courage, and they will move more carefully.

This plan of hiving will be found much better than the old method of shaking the bees into a hive and then turning it over upon a table or board. I have known the queen to be killed by turning over the hive, and more or less bees are always killed in the operation. If moveable comb hives are used, they should be so constructed that the bottom board may be dropped at the rear of the hive for the purpose of putting in the bees when hiving. Swarms should never be allowed to stand where they are hived until evening, as is the practice with some, but should be moved at once to their stands, as some of the bees will go into the field to work in ten minutes after they are hived; and if left until evening large numbers will have commenced to work, and having marked the spot will return there the next day, and not finding the hive will wander about, and many will be lost. Second swarms are generally far more irritable than first or top swarms, hence these are far more likely to sting; but cold water will soon quiet them, and they may then be hived with safety.—(*American Paper*.)

SILKWORM-REARING IN ENGLAND.—No. 12.

The Mount and the Crop.—On the first appearance of maturity among silkworms, the "mount" has to be provided for. Silkworms are termed "on the mount" when full-grown, and seen crawling to the materials among which they are to spin.

Towards the period when the worms mount, the most forward should have been removed to the top stage but one, and so in succession lower down for the later ones. This might be done at the previous change, or clearing-off of the refuse, &c. The insects must not be handled roughly at any time, especially when large, and near spinning. Care must be taken when placing them in their spinning quarters not to let any fall to the ground, or they might burst, letting out the silk-forming fluid.

Whichever of the systems I have before described be adopted, the upper stages next the ceiling are to be first prepared, and the others in succession, by placing the spinning materials in rows across them, at 18 inches apart, so as to give easy admission to the trays, when placing the worms between.

In using brooms according to ancient custom, their tops should be sufficiently long and elastic to bend beneath the ceiling or stage, forming an arch, their bottom part standing on the cross pieces of the compartment of the stage below, and not on the paper on which the worms are, for that should be left at liberty, so as to be removed with all excrements, &c., after the mounting. None of the brooms must in the least extend or lean outside the stages, otherwise many worms might fall to the ground. Their branches should spread out in fan fashion, as well to allow of the free circulation of the air as to afford room for the insects to labour.

Having placed the brooms in position many ripe worms will easily find their way into them, but any not doing so may be gently placed near them, and this is a necessary attention during the entire mount.

Several Italian authors recommend laying light, dry branches or twigs of oak, elm, &c., over the worms for these to crawl on, then to bring the branches near the feet of the brooms. During the mount give the worms between the rows frequent light meals, in order to hasten their spinning. As soon as the greater part of them have mounted, clear away the refuse, without disturbing the spinning materials, placing the remaining insects in a smaller space, otherwise too many leaves will be wasted in feeding them.

I would impress on the rearer the necessity of constant ventilation during the mount, and the expediency of using fire heat if the temperature falls too much below 70°; for the worms, if subjected to much cold, cannot eject the silken thread in consequence of the silky matter being hardened.

As I have previously described the various ways of arranging the spinning materials, it is unnecessary to say more now, but I particularly like using laths for placing the brooms on. The bridge system, and that in which the materials are already partly arranged, are good, and so, doubtless, is that of Count Delprino. Whichever of the first methods be adopted, it is desirable at each end of the stages to form a kind of fence 3 or 4 inches wide, by simply laying materials up to the stage

above, and so securing it firmly from falling. All the most forward worms should be mounted in one of the castles, and those that are two or three days later consigned to the other. None, in fact, should be allowed to mount in the same castle after the fourth day. Any so much behindhand will be better removed to a temporary stage apart from the others, perhaps at the side of the room, and rather nearer the stove, there to be supplied with food and spinning materials, the latter placed in rows about 18 inches apart, and covered at top with paper, under which the worms will work. It is customary with the best Italian rearers to transport these backward worms, called "pigri," or lazy, to another ventilated room, where they are treated to a temperature of 75°, or even 80°, placing them between the rows of materials ready prepared on the requisite number of stages. The most suitable material to use in this case would be a mixture of shavings, dried spear grass, and pea haulm, in which the worms work readily.

With all the care exercised in placing the spinning materials on the stages so as not to extend beyond the sides, it often happens that some worms do fall to the ground, and to prevent their destruction by breaking the fall, it is proper to place straw, shavings, &c., on the floor round the sides of the castles, and there cocoons will be produced which otherwise would be lost. Some rearers make the middle and bottom stages of the castle 2 inches wider than the rest in order to catch the falling worms, and this is not a bad precaution.—LEONARD HARMAN, JUN.

OUR LETTER BOX.

DUCK LAYING IRREGULARLY (*Duck*).—Ducks, like fowls, form the egg, but they wait help for the shell. Fowls seek for pieces of chalk, failing which, they pick mortar from between bricks. The skin of oaks contains much lime or chalk, and is therefore good to give. In a state of inflammation the eggs are often obstructed. The application of the oiled feather was proper and successful. It should have been repeated. The egg would then have been laid in due course, although the shell was weak, unless it were broken. A broken egg in the passage is certain death. Have your Ducks access to water? if not, make them a puddle; put in gravel and a few oats. They will then get right.

HENS FOR LAYING ONLY (*Quite a Beginner*).—Hens will lay quite as many eggs without a cock as with him. Some say they lay more; we are not able to dispute or affirm that. Cocks are needed only to render eggs fertile, and have nothing to do with the production of them.

ERRATA.—In seventeenth line from bottom of first column, page 429, "fine match cocks" is printed "fine March cocks." Also, in the article in the Number of May 21st, second column, twentieth line from top, page 382, "strains of the same colour" is rendered "strains of the Game colour."

BOOK (C. T.).—Taylor's "Bee-keeper's Manual." Get also "Bee-keeping for the Many," price 1d., and "The Gardener's Almanack" for 1868, price 1s. Either or both of these may be had free by post direct from this office at the cost of an extra stamp for each.

DRIVING BEES (*Sussex Bee-keeper*).—We cannot tell why you failed to drive your bees, but should advise you to "try again," as we have known a novice succeed under precisely similar circumstances. When bees return to their hive after having swarmed, it is generally found that their queen is missing; but we know of no reason why this accident should be more common in the present than during former years.

TREATMENT OF WEAK STOCK (*A Lover of Bees*).—We do not see that you can do more for your bees than you have done. The stock will probably raise another queen, and may next season be a strong one; but the rapid increase of buildings around you is by no means conducive to successful bee-keeping.

FEEDING CONFINED BEES (*M. J. Lockerbie*).—When you directed bees to be confined "for two or three days," stating afterwards that they "should be liberally fed during the period of incarceration," there can be no doubt that, whether intentionally or unintentionally, you did in point of fact recommend the liberal feeding of confined bees. Not being now in our novitiate there was of course no risk of our being misled into following your instructions, and we related our early experience in order to put others on their guard. If you intended to convey any other meaning than that which your words implied, you should certainly have been more explicit.

PIGEONS SITTING FOR WEEKS (*Poster fauvier*).—We fancy the hens you mention are very old ones. We meet with nothing of the sort among ours.

PIGEONS (*Fred. Ken*).—You were treated ill by the party who returned the hen after having kept her long enough to have eggs from her; but you received her back, and have no remedy.

YOUNG DOVES DYING (*Fontaine*).—If young Doves or Pigeons are found dead in the nests with their crops full, they have died from cold; if with their crops empty, from starvation. Feed your old birds on wheat and canary seed. Tares though excellent for Pigeons are fatal to Doves. Avoid hempseed, except a very little in cold weather. Perhaps you have given this to your birds too freely.

CANARIES (*W. D. S.*).—Mr. Blackston's address has been published in this Journal. It is 22, Norfolk Street, Sunderland. You can have Brent's "Canary, &c.," from our office, free by post, if you enclose twenty postage stamps with your direction.

TEACHING A GOLDFINCH TO SING (*A Subscriber*).—We never heard of a Goldfinch being taught to whistle a tune. We imagine it is a bird that could not be taught to do so. In Germany Bullfinches are taught by constantly playing a small bird organ to them.

DEATH OF CANARY (*A Young Soldier*).—We could not detect the cause of death; decomposition is rapid in this weather. There is nothing amiss with the seed and sand you enclosed. Birds are benefited by green food daily. Brent's "Canary and other Cage Birds" can be forwarded to you free by post if you enclose twenty postage stamps with your address.

REWARD (*J. Wright*).—Your proposed advertisement is a libel.

WEEKLY CALENDAR.

From observations taken near London during the last forty-one years, the average day temperature of the week is 73.3°; and its night temperature 49.3°. The greatest heat was 93°, on the 27th, 1846; and the lowest cold 34°, on the 26th, 1862; 28th, 1861; and 30th, 1873. The greatest fall of rain was 1.18 inch.

BUDDING AND GRAFTING PELARGONIUMS.

NOTICING in page 412 a reply to a correspondent on the subject of Pelargonium grafting, and that the opinion is expressed that you "do not think budding would be successful," I am induced to send you a few particulars of some experiments which I have recently been carrying on in that way.

Having last autumn a number of strong-growing seedling Zonal Pelargoniums, which, on flowering, proved to be of no value in themselves, the idea occurred to me of trying the effect of budding and grafting Pelargoniums of different sections upon them, and I at once selected a few of those having the straightest and strongest stems as stocks for working upon, principally with the object of making standards. The following are some of the results:—

In the second week in November I inserted in one of the stocks above referred to, two grafts of a variety of Fancy Pelargonium named Profusion, and in another stock four buds of the same variety. One of the grafts took, and has since grown well and flowered freely. Of the four buds inserted in the other stock, one went off; the others remained inactive until the commencement of this year, when two of them commenced growing, slowly at first, but have since become gradually more vigorous, and are now forming a nice head to the stock; the fourth bud also started to grow a short time ago, after being inactive for more than four months, and although it has not taken so well as the other two, it is gradually gaining strength. Another bud, inserted in the same stock on the 18th of February to replace that which went off, is just now starting into growth.

I may here state that the stock upon which these buds are worked is a very strong one, with a clear stem 2½ inches in circumference, and 2 feet high to where it first branches out, and it was in four separate branches that the buds were inserted, one in each. The buds have not yet flowered, but (and here let me state that this was one of the main objects I had in view when putting in the buds), the leaves are, up to the present time, very perceptibly altered in their character from the original by the influence of the stock: whilst in the case of the grafted plant the stock does not appear to have had any influence in altering either leaf or flower. Whether the stock will have any influence in changing the character of the flowers on the budded plant remains to be seen, but I think it will not.

The next most successful result I have had is with the Ivy-leaf section of Pelargonium budded on the before-mentioned seedling Zonal stocks. On January 15th this year I inserted a bud of the old White Ivy-leaf in a stock at a height of 2 feet from the pot; this is now growing very rapidly, is forming a fine head, and has been several times stopped. It has flowered, but the stock in this case does not appear to have had any other influence in altering the character of the budded variety than giving it more vigour. I have also two stocks budded with *Peltatum*

elegans (Ivy-leaf), at 2 feet high, the one budded in February and the other in March. The former, which has two buds upon it, has flowered, and is growing rapidly, and making a fine head. The latter has four buds upon it, all of which have started to grow.

On another stock, also budded with *Peltatum elegans* at 4 feet high with two buds, both buds are growing. Another stock I also budded in March, at 4 feet high, with the new variegated Ivy-leaf *L'Elegante*, one bud on which out of two put in was just starting to grow, when, through an accident, the top of the stock was broken off about 8 inches below the place where the bud was inserted, and, to show how well the bud in this instance had taken to the stock, the broken top was put in as a cutting, and is now rooted, and the bud starting into fresh growth. In the early part of April I inserted two buds of the Fancy Pelargonium *Cloth of Silver*, using for the stock in this instance the scarlet Pelargonium *Donald Beaton*, with a clear stem 2 feet high, both buds are just starting into growth, and appear to have taken well.

On another stock, a Zonal seedling, I put in on February 22nd the following varieties, commencing at about 8 inches from the base of the stock, and inserting a bud just above the base of every leaf up the main stem. The first bud from the bottom was **Bijou*, then came *Madame Vaucher*, **Waltham Seedling*, *Pink Stella*, **Violet Hill*, **Brilliant*, **Madame Vaucher*, **Mrs. Pollock*, *Christine*, **Bijou*, and *Luna*. These marked with an asterisk are all growing, and I believe every bud would have taken had the stock been in better condition when the buds were put in, but at the time the bark did not run well.

Another Zonal seedling stock I have budded with a large-flowered Pelargonium, which is growing, and just coming into flower. I have one or two other cases not worth describing; besides, the above facts will be sufficient to show that budding Pelargoniums may be carried on successfully, and certainly in my case it has been to me a most interesting experiment. I am not aware if the same thing has been tried before—that is, with regard to budding one section upon another. Of course the grafting of Zonal Pelargoniums one variety on the other is an old affair, but I do not remember to have ever seen any account of budding having been tried, but possibly it has.

With respect to the Ivy-leaf section, I believe the fact that it can be successfully budded upon the common Zonal varieties will prove useful, as plants worked as standards, say from 2 to 6 feet high, would form fine objects for conservatory decoration, and particularly when they can be so quickly and easily obtained of the desired height, which they can be by sowing seed of any strong growing Zonal variety, and letting the seedling plants run up to the required height for working upon. What a fine object a plant would be if worked, say at 5 or 6 feet high, on a good stout stock with some of the new variegated Ivy-leaf varieties, and allowed to hang naturally down after being properly stopped a few times to form a good head.—*J. H. Mason, Prince's Park, Liverpool.*

P.S.—I may state that the method of inserting the buds is just the same as in budding a Rose, and that the bud is

simply tied round with a bit of soft mat. I may add that I have had a number of huds that have not taken; but on the whole the experiment has been successful. I find the Ivy-leaf varieties take, perhaps, better than any.—J. H. M.

SEDUMS AS EDGING PLANTS.

THE increasing demand for hardy plants capable of taking the places of tender ones in the flower beds has been the means of bringing into notice more than one of the favourites of bygone years as well as fresh subjects not hitherto employed in the flower garden. The plants up to this time most sought after have been those of a dwarf compact habit of growth, and producing a long continuance of flowers, or remarkable for their foliage. The Saxifrages, Violas, Gentians, and other genera have furnished recruits to the army of edging plants. Not a few likewise have contributed materially in producing the equally important spring display. There are, however, some low-growing plants of whose existence many may not be fully aware, and as their easy culture places it within the means of everyone to grow them, they cannot be too well known. Those which I shall mention are all dwarf, quite hardy, and interesting to the lover of plants as well as to the botanist; and I am not sure but that those who delight in high flaring colours will find a relief in contemplating the sober yet far from dull hue of the plants about to be described, and which are not by any means new.

SEDUM CALIFORNICUM.—This fleshy-leaved Houseleek differs from the kind so often met with on the tops of low buildings and other places where it is grown for its supposed medicinal properties, as the Californian Sedum is of more sturdy habit, and the leaves are all deeply tipped with purplish brown. The plant seems to thrive well in most situations, but likes a dry and sunny one, increases freely, and bears transplanting at any season. It forms an admirable edging to a small bed, and for places where a permanent edging is required it is extremely suitable. Occasionally it flowers, but not frequently, and when it does the sturdy stem bearing a head or corymb of flowers is not without beauty. It is less disposed to flower than either of the following two species. In habit of growth it much resembles the common Houseleek, the thickly-clustered heads pushing each other out of place, and by degrees rising into a sort of mound. As already stated, it is not particular as to soil, but likes the sun.

SEDUM GLAUCUM.—Differing widely from the preceding, this low-growing spreading plant quickly occupies its allotted space, and unlike many others may easily be kept to that line. It is of a pale whitish green colour, and looks well all the year round. About the middle or end of May it flowers abundantly, the bloom being of a greyish tint, not by any means unsightly, but rather the reverse when viewed from a distance. The plant prefers a dry situation and grows very fast, so that when once it has established itself it quickly covers the given space, and it does not seem to die off when it becomes old. Although I have had it in use for several years, I have never known the centre or old portion of the plant die off or grow into an unsightly lump; on the contrary, it would preserve its original height of about 2 inches, and the flower does not rise more than 2 inches higher. The plant appears to accommodate itself even to the most prominent point of rockwork where there is only a very small quantity of soil. I have used it occasionally in winter gardening, and the grey hue of the plant was seen to advantage when the soil was dark-coloured with moisture. For a permanent edging it is all that can be desired in habit.

SEMPERVIVUM GLOBIFERUM.—In habit this is more like Sedum californicum but is less robust, and the whole plant is of a deep emerald green, the opening foliage looking like a partially-opened Rose bud. In most respects it resembles Sedum californicum, excepting that it flowers more freely, and the individual flower stems are remarkably sturdy for so small a plant. I believe it is less plentiful than either of the first-mentioned two, but I have had it for several years, and the hardest winter does not take any effect upon it. Like the other members of its family it delights in sunshine and a dry situation, yet with me it is grown in many instances as a permanent edging around small circular beds containing a young specimen Pinus or other tree, and for such a purpose it, as well as the other two Sedums, is admirably adapted. It may be admired every day in the year, which is not the case with many ornamental objects.

I hope to continue this subject on another occasion, as there

are other deserving plants not sufficiently known to the general public, but those named I have had for several years, and can highly recommend where economy and a prolonged good appearance are desired.—J. ROBSON.

NOTES ON GLADIOLUS.

A CORRESPONDENT in a contemporary, who hails from Dundee, and styles himself "DAVE DIBBLE," is very strong upon the subject of Gladiolus spawn; and in reference to a statement made in this Journal, that Gladiolus spawn blooms the first year of planting, expresses himself plainly to the effect that he does not believe it. He cannot get his Gladiolus spawn to bloom the first year. If he were in my garden now, I could show him some which will do so this year; only then, perhaps, he would say that the bulbs must be older than I said.

When Gladiolus bulbs are taken up there will be, according to the variety (some being much more productive than others), a number of bulblets, varying in size from that of a pin's head to a filbert. Now, I do not mean to say that every one of these will bloom the next year, but that if you can get them of the size of a pea or upwards without any trouble these will flower the next season. Some do as I have done when I had time for it—viz., plant them at once in pots, leaving them nearly dry during the winter months, and starting them into growth in the spring. Others keep them dry, and do not plant them until the spring, and if the outside skin be carefully taken off their growth will be considerably quickened. There is no mystery about it; and although "DAVE" does not believe it, I can assure him that in the south and in France it is constantly done, and surely the Scotch growers, who in all florists' flowers so excel, can give their testimony that this is the case.

The present season, trying as it is to all flowers, is especially so to the Gladiolus; and all growers of it would do well to mulch their beds or cover them with cocoa-nut fibre refuse, which is much neater, and give copious waterings. I fear that in all light soils it will be very difficult to keep Gladioli alive, and even in deep soils great care and attention will be required. I almost wish now that I had erected some kind of protection over some of my beds to keep off this broiling sun, but not having done so, must only keep the water-pot going. Happily I have a good supply of the precious element, and my soil is naturally close but not over stiff. As yet I see but little, if any, symptoms of the disease which proved so fatal to my collection last year; and as it developed itself long before this period, I am in great hopes that I shall escape, in some degree at any rate: but should this long drought continue what hope of a good bloom can we have? The flowers will no sooner show themselves than their beauty will be gone.

As far as I have been able to see, the new varieties are remarkably vigorous, Semiramis, La Fiancée, Norma, and Princess Alice having very strong grass, and looking as if they meant to do work. This, as in all florists' flowers, is a great point; for it is most trying to give money and expend time on them, and then after all to find that they will not repay one for either. This is the case in Roses. Such kinds as Madame Furtado, Souvenir de Comte Cavour, Joséphine Beauharnais, &c., are very beautiful, but so terribly miffy, that after a little while, under the same care that others have received, they go off; and so with sorts like Achille, Napoleon III., &c. It disfigures the bed to find them failing.

It seems strange and is much to be lamented, that no encouragement is given to the Gladiolus in or near the metropolis, save at the Crystal Palace. Surely now that it is becoming more popular, an effort might be made to make a Gladiolus exhibition at the end of August or beginning of September, and to invite growers from all parts to join it. If we could devise anything on the principle of the National Rose Show, and hold the exhibition at the same time as the Crystal Palace Autumn Show of Flowers, the Company would give every facility and act with their usual liberality. Many Gladiolus growers would hail it with much satisfaction. I can only say that if such a proposal meet with favour I shall be happy to receive any communications addressed to the office of THE JOURNAL OF HORTICULTURE. I would also willingly subscribe towards it, and do my best to exhibit as well. It is a matter worth thinking about, for there is no autumn flower more deserving of cultivation. Growers would perhaps meet; we might discuss disease, best method of growth, habit, merit of new varieties, &c.

I hope to see in a few days M. Souchet's collection, not in

flower but in the growing state, and shall then be able to say what I think of his method of growth, and to report how they look this season.—D., *Deal*.

FRUITING OF THE ROSE APPLE.

In the year 1853, when I had the care of the large conservatory at Chatsworth, under the late Sir Joseph Paxton, I fruited the *Jambosa vulgaris* (*Eugenia jumbos*). The trees then stood on the north-west quarter, and must have been planted from fifteen to twenty years. They were between 12 and 15 feet high, and about 12 feet through. Being in very robust health they did not produce much fruit. I believe the Rose Apple has now been in this country nearly one hundred years, and I have no doubt it had been fruited even before the above date.—T. JONES, *the Gardens, Ribston Hall, Wetherby*.

In regard to several communications in late numbers of THE JOURNAL OF HORTICULTURE concerning the fruiting of the Rose Apple, it has occurred to me that it will be interesting if all who may have fruited it would send an approximate statement of the time and place of its fruiting, and so the date when it first fruited may be set at rest.

I can myself state when and where it was fruited anterior to the dates already noted in these pages; but before I do so it may be well to rectify a slight error which has crept into the discussion concerning the award lately given to fine examples of this fruit by the Fruit Committee of the Royal Horticultural Society. The certificate was awarded to the fruit as being exhibited for the first time at the Committee's meetings in a properly ripened state; and so well developed was the fruit that it met with the Committee's approbation in the points stated in the report, and upon which that body is bound to adjudicate. The fact that the Rose Apple has been fruited before does not confirm anything concerning its flavour.

The Rose Apple was fruited in the plant stove at Dynevor Castle, South Wales, in 1850. The plant was grown in a large pot set upon a tan pit, had a fine clean bole, was about 5 feet in height, had a round head about 3 feet in diameter, and bore from six to eight fruit. The fruit was of a somewhat peculiar flavour, otherwise it does not occur to me now to have been very remarkable for excellence. I would not venture to say whether the examples were good of their sort or not; certainly they were not so good as those lately exhibited. The gardener at Dynevor at that time was my late lamented friend Mr. Henry Bundy.—WILLIAM EARLEY.

THE COMMON AND COLCHIAN LAURELS.

In reference to the hardness of the Colchian Laurel, I beg to say, for the information of your correspondent, Mr. Robson, that its capabilities of withstanding the severities of a hard winter have been well and sufficiently tested in this establishment many years ago, having passed through that ever-memorable winter, to horticulturists, of 1860-61.

As many thousands of this invaluable Laurel are grown in this nursery, I have had many opportunities, especially during the spring of 1867, of pointing out to visitors its merits as contrasted with the old common Laurel, large numbers of which were occupying an adjoining piece of land. Seen at a little distance, the latter had more the appearance of a "quarter" of young Beech, they were so brown, than Laurels, while our Colchian friend was as "green as a Leek."—J. MAYOR, *Walton Nurseries, Liverpool*.

In this neighbourhood nearly all the common Laurels were killed down to the ground by the severe frost of January, 1867, but as far as I had an opportunity of observing, the Colchian Laurel was quite uninjured.—F. L. S., *Blackheath*.

BUDDING MARSHAL NIEL ROSE ON GLOIRE DE DIJON.

THOSE of your readers who possess a strong plant of Gloire de Dijon, will be well repaid if they devote a part of it to Marshal Niel. Two years since I budded a shoot about half-standard high; last year by closely pinching all the shoots I formed a bushy head, which this year is a glorious cluster of blooms. The stock appears to have sufficient influence to colour the outer petals of a rosy buff, closely resembling the

Gloire de Dijon; the inner petals are the deepest yellow, and the flowers are wonderfully solid and well formed.—T. F. R., *Sawbridgeworth*.

BRITISH FLOWERING PLANTS.

It may not be generally known, that some of the Narcissus family grow wild in certain districts; for instance, near here, both on cultivated land, and in many places in the woods, where, in all probability, the soil has never been under cultivation. *Narcissus uniflorus* grows by the thousand. A neighbouring farmer last spring ploughed up a field which had been two years in grass, and after the harrows had been over the land one could very soon have picked up half a dozen bushels of the bulbs.

This *Narcissus* comes very early into flower, and its flowers are very sweet-scented; but some people consider them unpleasant when a handful is kept for a short time in a close room. Still, being such an early-flowering plant (it flowers in March), it will always be welcome. Many of the thimble-like cupped flowers are very delicately fringed round the mouth. The flower stems being strong, and the flower itself capable of being carried to a distance and afterwards remaining in good condition for days, many an unwelcome hand from the nearest towns ruthlessly pulls thousands of the flowers, no doubt for sale.—G. DAWSON, *Chilworth, Romsey*.

MY ORCHARD-HOUSE JOURNAL.

May 25.—The first Cherries ripe, the Guigne Très Précoce, a round black Cherry with a short stalk, the earliest of all, and very sweet.

May 30.—The Early Purple Guigne Cherry quite ripe. Stalks very long and slender; fruit large, of a deep purplish black, very beautiful, and most delicious. This sort is too delicate for open-air growth unless against a wall, and is very liable to gum. The Guigne Marbrée Précoce Cherry ripe. This is the sort sent from France to London early in the month; its colour marbled red, and its flesh hard and flavourless. When fully ripe its colour is dark purple, and its flesh melting and juicy.

June 3.—Cherries, a sort much like Early Purple Guigne, Noir Précoce de Strasse, Bigarreau Jaboulay, and Belle d'Orleans, ripe. The second is a rather small black Cherry, now dead ripe, and very sweet.

June 10.—Early Lyons Cherry (*Hâtive de Lyons*), ripe. A very large dark red fruit, of firm flesh and excellent flavour. Werder's Early Black, ripe.

June 14.—Cherries Bradford Prolific, Black Tartarian (with larger fruit than the Prolific), Napoléon Noir, with very small stones, Brant, Large Black Bigarreau, Black Hawk, Bohemian Black Bigarreau, and a host of other large black Cherries ripe; all remarkably rich and good, owing to the sunny weather.

June 18.—Montgamet Précoce Apricot ripe; rather small, juicy, and agreeable, the earliest of all. I saw this sort in the beginning of the month at Messrs. Webber's in Covent Garden. The fruit had just arrived from Bordeaux.

June 20.—Sardinian Apricot (*Abriéot de Sardaigne*), ripe. Under glass this is a delicious fruit; its flesh is white, juicy, and like a sweetmeat. Précoce d'Oulins Apricot commencing to ripen. This is a few days earlier than the Oulins Early Peach, but is not so rich.

June 22.—The Early Beatrice Peach commencing to colour. This is as yet the earliest Peach known.

The following are the registers of temperature for the week just past, in dense shade in the open air, and the same in the orchard house at 2 p.m. each day:—

	Open air.	Orchard house.

—T. R.

VARIETIES OF THE GENUS VIOLA.

I OBSERVED in page 423, some remarks by Mr. J. Wills on a new white *Viola*, *Viola cornuta alba*, which he anticipates will become an especial favourite for edgings, its foliage being neat, and its habit compact and procumbent. He also considers that it will form a fine associate to *Viola cornuta* and *lutea*.

Being like Mr. Wills an admirer of the Viola tribe, I last year began to hybridise, with the view of obtaining improved varieties. I crossed Viola cornuta with the Imperial Blue Pansy, but I am sorry to state that I could not get a seed to come up. I have also crossed Mr. Tyerman's Viola montana, but I cannot say what the result may be.

I liked the habit of Viola lutea well, but not the flowers; they were so unshapely and paltry-looking. To improve it I crossed a few flowers carefully with blues, and the best yellow compact-growing Pansies, and I am pleased to say I have in a great measure attained my object, for the seedlings which have already bloomed have flowers very superior in shape to the original plant. Already I have a variety of a deeper yellow than the original, a primrose-coloured one, and a third which I mean to call Viola lutea striata, in which the upper petals of the flowers are distinctly striped with blue. The flowers of all are much superior in shape to those of Viola lutea. I have many other seedlings to flower, and should any prove of value, I will send an account of them.—WILLIAM MELVILLE, Dalmeny Park.

NOTES ON THE ROYAL HORTICULTURAL SOCIETY'S PELARGONIUM SHOW.

Few, I think, could complain of the manner in which the prizes were awarded at the Special Prize and Pelargonium Show, held at South Kensington on the 16th and 17th inst. It was evident the Judges were alive to their duty. They very properly disqualified several fine collections, owing to these not being exhibited in accordance with the wording of the schedule. This is as it should be, and a few more examples like this will make exhibitors more careful, and the part to be performed by the judges will thus become much more simple and agreeable.

Many and various are the opinions as to who has the best Gold or Silver Tricolor Pelargonium, and so changeable are these varieties, that it is not often that one can be shown in really good condition many times in succession. It is only, therefore, when any particular variety happens to be in good condition just at the time the exhibition takes place, that its owner can hope to gain a prize with it.

In glancing over the numerous and beautiful collections exhibited the other day, few plants could be found amongst them having a decided and permanent character like Mrs. Pollock. The young leaves were bright and beautiful as butterflies, but their beauty only lasts a short time. No plant could be found with any of the fully-developed leaves retaining their beauty so long as Mrs. Pollock does; for this reason Mrs. Pollock will retain its position, the same as Flower of the Day has done, for many years. I consider, therefore, the Judges did quite right in bestowing their highest favour on Mrs. Grieve, for in my opinion it was decidedly the best variety exhibited on this occasion, and the only one likely to become a formidable rival to the beautiful Mrs. Pollock. It appears to have the same freedom of growth that Mrs. Pollock possesses; there is a good substance in the leaf, and, above all, a good foundation of green in the composition of the leaf. This will enable it to retain its beauty for a much longer period than many of the other varieties which appear for the time more beautiful and bright than Mrs. Grieve.

The next best Golden Zonal, in my opinion, is Sir R. Napier, exhibited by Messrs. Carter & Co. It is perfectly distinct from everything else exhibited on this occasion, and appears to possess a good constitution. It has a neat and compact style of growth; the leaves are flat, of good substance, with a splendid crimson zone waved with blackish velvety crimson. To the above may be added Masterpiece, Howarth Ashton, Prince of Wales, Mrs. Darnett, Ettie Beal, and Countess of Craven.

Amongst the Silver Tricolors, Miss Burdett Coutts stands first, in my estimation. Mrs. John Clutton is also good. To these may be added Lass o' Gowrie and Princess Beatrice.

Amongst the Bronze and Gold Zonals, Criterion must be considered a splendid variety, only suitable, however, for pot culture. The plant exhibited by Messrs. F. & A. Smith was a splendid mass of colour, and was deservedly awarded the first prize. Mrs. Simpson and Arab are also fine varieties.

Amongst the Golden self varieties, Golden Emperor, from Messrs. Saltmarsh, was decidedly the best.

First-class certificates were awarded to Mr. W. Paul and Messrs. E. G. Henderson on this occasion for the beautiful double-flowered Pelargonium Madame Lemoine, the best of all the double-flowered section. The habit is very dwarf and

compact, and, unlike most of the other double kinds, it is a very free-flowering variety. The flowers, which are very double, and of a pretty peach colour, are borne on stout footstalks well above its neat foliage, which is slightly zoned. This will, undoubtedly, become one of the most popular plants of the day.

Amongst the subjects for the awards of the Floral Committee, Mr. C. Noble exhibited Spiraea palmata, one of the handsomest hardy plants in cultivation. It has fine, dark green, palmate leaves, and above these are produced immense clusters of bright peach-coloured flowers, which are double. It is, certainly, a most graceful and useful plant, and if it will bear forcing in pots like the Hoteia japonica, will prove one of the most valuable decorative plants we possess. It was deservedly awarded a first-class certificate. I predict a brilliant future for this lovely plant.

Mr. Cole, of the Worthington Nursery, exhibited a beautiful seedling Fern, Lomaria gibba crispa. This handsome Fern was also awarded a first-class certificate.

Messrs. E. G. Henderson produced a grand display with their little square wooden boxes, in which were exhibited one hundred species and varieties of plants suitable for bedding purposes. This was, undoubtedly, the most interesting feature of the Show; it was not only interesting, but highly instructive to the flower gardener, for a very large number of plants were here brought before him, which would at once suggest their use in bedding arrangements. The way in which these were arranged reflected the highest credit on Messrs. Henderson and their skilful assistants. At some future time I shall give a list of flowering and other plants suitable for producing fine combinations with many of the little gems in this exhibition. It is to be hoped that Messrs. E. G. Henderson will still retain this pretty collection of plants in the boxes just as they were exhibited at the late Shows at Kensington and Regent's Park, so that many gardeners who may have been prevented from seeing them on the occasions referred to, may see them at the nursery, where they will find many other subjects that will prove quite as interesting, if not quite so instructive.—J. WILLS.

CRYSTAL PALACE ROSE SHOW.—JUNE 20TH.

As might have been expected, the Roses even thus early have shown unmistakable symptoms of the effect of the scorching, almost tropical weather, which we have had for some time. Never, probably, were so many Roses shown out of character as they were on this occasion, and more especially was this the case with the dark varieties, the colour being fairly driven out of them by the sun. Some kinds were really hardly distinguishable; notably was this the case with a box of John Hopper, which no one could have recognised as that fine variety. Charles Lefebvre in many boxes had a mottled appearance, also, to doubt, the effect of the sun; but although this was the case, and it may seem a strange anomaly, yet I may also add that I never saw finer blooms of some varieties, but then they had been evidently bloomed under shading. Thus, for example, in Mr. Hedge's and Mr. Pochin's boxes there were blooms which were, beyond doubt, as fine, as fresh, and clean as we have ever seen them. Some wonderful boxes of yellow Roses were exhibited; amongst others by Mr. Hedge and Mr. Cant, Marechal Niel, L'Enfant Trouvé, and Triomphe de Rennes, were exceedingly fine.

Leaving, however, other hands to deal with this portion of the Show, I would confine my observations to the new Roses, of which there was not a very plentiful supply, some of the boxes, too, being disqualified for not complying with the rules, which only admitted Roses sent out in 1866 and 1867. Mr. Keynes took the first prize, and Mr. Cant the second. Among the best Roses of 1866 were Felix Genero, François Treyve, Horace Vernet, Madame George Paul, colour somewhat flown, but a fine Rose in cool weather; Mademoiselle Annie Wood, a first-class Rose of bright colour; Monsieur Noman, a Rose I had too hastily condemned; it is very fine, in the way of Marguerite de St. Amand, and a box of it shown by Mr. Cant was most lovely. Thorin is bright, but has too little stuff in it; Boutin d'Or, Tea, is excellent, and Madame Margottin, very fine.

Of the Roses of 1867 but very few were exhibited. Madame Noman is a lovely Rose in the style of Mademoiselle Bonnaire, and Virginal, white with light flesh-coloured centre; Baronne Adolphe de Rothschild, a lovely light pink if it is full enough—as shown it was not; Prince Humbert, very bright, but its shape not what I should like; but I think the new Roses must be respite for another time, for it would be very unfair to judge of them this season, when Roses are so out of character. I think we may say, however, that Roses which show now well will be worth keeping.

It falls quite within the legitimate sphere of floral notices to draw attention to the very beautiful decoration of the Royal Box, showing that the tasteful decoration of rooms is not a *specialité* of our French neighbours, for it is entirely owing to the good taste and judgment of Mr. Wilkinson, the able and active manager of the flower shows, that

the central hall, if we may so call it, is a marvel of beauty. A fountain plays in the centre, surrounded by fine-foliaged and dowering plants of great beauty, while through an opening on one side is seen a water nymph, with a fountain casting down a sheet of water all round, lighted from above by gas, which brings out beautiful prismatic colours in the water. It is a most charming arrangement, and does infinite credit to the designer.—*D., Deal.*

NOTWITHSTANDING the recent scorching weather, the display of Roses at the Crystal Palace on Saturday last was excellent in quantity, and in quality vastly better than even the most sanguine could have expected. Of course many of the flowers had been "touched" by the sun, and had, consequently, lost that freshness which constitutes so great a charm in a Rose, and many were showing stamens; but then again there were whole stands, and these, too, from a distance, in which the blooms exhibited all the freshness and perfection which one could have desired in the most favourable weather. On the whole, notwithstanding all drawbacks, the Show was magnificent, and despite the heavy rain which fell during part of the day and other attractions elsewhere, more than 13,000 visitors inspected the Exhibition.

In Class 1, for single trusses of seventy-two varieties, Messrs. Paul and Son took the first place with remarkably fine blooms, conspicuous among which were Duke of Edinburgh, rich crimson scarlet; Marie Baumann, a splendid earmine Rose of fine form, hitherto not frequently exhibited, but good in almost every stand in which it was shown; Madame Charles Wood, glowing crimson; Alfred Colomb; Mademoiselle Marie Rady, another brilliant-coloured variety; Senateur Vaisse, Xavier Olibo, Devoniensis, Francois Travy, Marechal Niel, magnificent, as indeed it was in most of the stands; Louise Magnan, fine white; Madame Victor Verdier, Maurice Bernardin, Lord Macaulay, Mademoiselle Therese Levat, Olivier Delhomme, Mademoiselle Annie Wood, Prince Camille de Rohan, and Mademoiselle Bonnaire, small, but beautiful. Mr. Cant, of Colchester, who was second, had fine examples of Marechal Niel, Madame Bravy, Madame Victor Verdier, Duchesse de Caylus, Niphotos, President, Elizabeth Vignerot, Gloire de Vitry, Olivier Delhomme, Prince Camille de Rohan, Souvenir d'Elise, Devoniensis, Celine Forestier, Horace Vernet, Maurice Bernardin, Marie Baumann, and others. Mr. Mitchell, of Piltown Nurseries, Uckfield, who came third, had also excellent blooms, and some very fine, such as Charles Lefebvre, Mlle. Marie Rady, and Charles Verdier. Mr. Keynes, of Salisbury, was fourth.

Class 2, three trusses of forty-eight varieties, always affords a rich and effective display, and on this occasion was quite a feature of itself. Messrs. Paul & Son's stand, which took the first prize, contained many remarkably fine trusses, especially those of Madame Furtado, Victor Verdier, Ville de St. Denis, Duke of Edinburgh, Beauty of Waltham, Niphotos, Madame Rivers, Marechal Niel, Marie Baumann, Maurice Bernardin, Mlle. Marie Rady, Pierre Notting, Alfred Colomb, Duchesse de Caylus, and Gloire de Santenay. In the second-prize collection, from Mr. Keynes, were Madame Vidot, Marie Baumann, Camille Bernardin, Charles Lefebvre, Marguerite de St. Amand, Princess Mary of Cambridge, Souvenir de Malmaison, Gloire de Dijon, Madame Sertot, Alba Mutabilis, Mrs. Ward, Elae rose, Bernard Palissy, confused-looking; Xavier Olibo, fine; Alfred Colomb, Mlle. Marie Rady, Francois Lacharme, Triomphe de Rennes, Boule d'Or, Madame Knorr, and Madame Willermoz. Mr. Cant, who came third, had also very fine trusses of some of the varieties just named, as well as Rubens, white, tinged with rose; Fisher Holmes, John Hopper, Comtesse de Chabrilant, Exposition de Brie, splendid colour; La Brillante, Dr. Andry, and Devoniensis. Mr. Fraser, of Lea Bridge Road, Leyton, took the fourth prize with, among others, Prince de Poria, very fine in colour; Fisher Holmes, Duchesse de Caylus, Marie Baumann, John Hopper, Madame Boutin, Madame C. Wood, Monsieur Nonan, and Antoine Ducher. Mr. Mitchell also exhibited in this class, but the warm climate of Sussex, which gives him so great an advantage sometimes, was against him, as the sun had somewhat affected his otherwise fine blooms. Messrs. Francis contributed good examples of William Rollisson, Madame Vidot, and some others.

In Class 3, for three trusses of twenty-four varieties, Mr. Keynes took the lead with splendid examples of Marechal Niel, America, Triomphe de Rennes, Souvenir d'un Ami, Souvenir de Malmaison, Devoniensis, Marguerite de St. Amand, Alfred Colomb, Victor Verdier, Mlle. Marguerite Dombria, Charles Ronillard, Princess Mary of Cambridge, and Charles Lefebvre. Messrs. Paul & Son, who were second, had Pierre Notting, Maurice Bernardin, Prince de Poria, Alfred Colomb, and others, fine in size and colour; whilst Mr. Cant, who took the third place, had a splendid example of Marie Baumann, and several others, very good. Mr. Clarke, Streatham Place, Brixton, was fourth. Mr. Cattell, of Westerham, sent, among others, Beauty of Westerham, a lively-coloured variety of English origin.

The next Class, 4, was for single trusses of the same number of varieties. In this Mr. Keynes was again first, and had a magnificent bloom of Marechal Niel measuring about 1 1/2 inches in diameter, and fine examples of Marie Baumann, Hippolyte Flandrin, Marguerite de St. Amand, America, Souvenir de Malmaison, Souvenir d'Elise, Souvenir d'un Ami, Charles Ronillard, and Pierre Notting. Mr. Parker, Victoria Nursery, Rugby, who was second, had Marechal Niel, not large, but extremely rich in colour, and excellent examples of Madame Victor Verdier, Charles Lefebvre, Alfred Colomb, and

General Washington. The third and fourth prizes went respectively to Mr. Clarke, of Brixton, and Mr. Maun, of Brentwood.

In the amateurs' classes the exhibitors were very numerous, and many of the stands were excellent, especially those shown by Mr. Hedge, Mr. Ingle, the Rev. E. N. Pochin, and Mr. Postans, which contained some superb blooms, and withal wonderfully fresh. We can only notice a few of the best varieties in each class.

For single trusses of forty-eight kinds, Mr. Hedge, of Reed Hall, Colchester, took the first place with Boule d'Or, Exposition de Brie, not large, but fine in colour; Prince Camille de Rohan, Rubens, William Griffiths, Madame Margottin, Triomphe de Rennes, Marie Baumann, Pierre Notting, L'Enfant Trouve, and Marechal Niel, the last of the richest golden colour. Mr. Ingle, gardener to Mrs. Round, Birch Hall, Colchester, who was second, had John Hopper, Senateur Vaisse, Charles Lefebvre, Pierre Notting, very fine; Rushton Radclyffe, Duchesse de Caylus and Souvenir de Malmaison. Mr. Thorneycroft, Floore, Weedon, was third; Mr. Chard, gardener to Sir F. H. Bathurst, Bart., Salisbury, fourth.

In Class 6, for thirty-six single trusses, Mr. Hedge was again first with remarkably fine blooms, especially those of Marechal Niel, very deep in colour; Dr. Andry, Madame Boll, and Alfred Colomb. Mr. Draycott, gardener to R. Studd, Esq., was second with Victor Verdier, Due de Rohan, Louis XIV., Olivier Delhomme, and Madame Bravy; and good trusses of other varieties came from him; from Mr. Keen, gardener to J. G. Sheppard, Esq., Camsey Ash; and from Mr. Ingle.

In Class 7, twenty-four single trusses, the Rev. E. Pochin, Sibby Vicarage, Loughborough, had the first prize for beautiful examples, both as regards size and freshness, of Senateur Favre, Victor Verdier, Souvenir de Malmaison, Charles Lefebvre, Madame Furtado, Dr. Andry, Due de Rohan, magnificent, Comtesse de Chabrilant, Jules Margottin, Louis Peyronny, Marechal Niel, Climbing Devoniensis, John Hopper, Marguerite de St. Amand, and Madame C. Wood. There was not a bad Rose in the stand, and the greatest credit is due to its exhibitor, as likewise to Mr. Postans, who took the second prize, and whose blooms were also excellent. Mr. Stoddart, Wivenhoe Park, and Mr. Nichol, gardener to T. H. Power, Esq., Bury St. Edmunds, were third and fourth.

The next Class, 8, was for twelve varieties, and in it Mr. Pochin and Mr. Postans were again first and second, exhibiting beautiful examples of Madame Furtado, Charles Lefebvre, Climbing Devoniensis, Marechal Niel, General Pelissier, Francois Louvat, Xavier Olibo, Niphotos, Abel Grand, Pierre Notting, splendid, Marie Baumann, Madame Willermoz, Madame C. Wood, Due de Rohan, and Madame V. Verdier. Mr. May, Slitted, who was third, had among others Marechal Niel, very fine, and the fourth-prize stand of Mr. Ingle contained a very large and fine Charles Lefebvre.

Collections of Roses, any variety, were furnished by Messrs. Paul and Son, who exhibited numerous varieties, and Mr. Cant, who had a stand of magnificent trusses of Marechal Niel. To each of these exhibitors a first prize was awarded, the second and third being taken by Messrs. Francis, of Hertford, and Mr. Hollamby, of Tunbridge Wells. The latter also sent several boxes not for competition, and received an extra prize.

Of yellow Roses, Mr. Keynes sent numerous fine trusses of Louise de Savoie, Gloire de Dijon, Triomphe de Rennes, Boule d'Or, and Marechal Niel, the last splendid, and he received a first prize; the second going to Mr. Hedge, who had L'Enfant Trouve, very beautiful; Jaane de Smith, Celine Forestier, Narcisse, and some of those just named. Mr. Stoddart was third, and an extra prize was awarded to Mr. Bristow, gardener to Mrs. Orme, Broadwater.

For Tea-scented and Noisette varieties there were classes both for nurserymen and amateurs, Mr. Cant, Mr. Fraser, and Mr. Parker, of Rugby, being the prizetakers among the former; and Messrs. Hedge, Bristow, and Postans among the latter. In the various stands shown by these gentlemen, there were beautiful trusses of Niphotos, Madame Willermoz, Marechal Niel, Devoniensis, Comte de Paris, Moiret, Souvenir d'Elise, Vicomtesse de Cazes, L'Enfant Trouve, Madame Margottin, a fine new pet Rose; Gloire de Dijon, and Celine Forestier.

The best basket of one hundred flowers was one of Marie Baumann, from Messrs. Paul & Son; Mr. Fraser being second with Madame Victor Verdier interspersed with Asparagus, and Maiden-hair and other Ferns; and Mr. Chard, third.

Among miscellaneous subjects were collections of bedding plants from Messrs. E. G. Henderson; Downie, Laird, & Laing; F. & A. Smith; and Mr. Maun, of Brentwood. Mr. Guyett, gardener to J. Perrott, Esq., Herne Hill, sent finely-fruited Vines in pots; M. Van Houtte, Iresine Lindenii, with purplish chocolate leaves; and G. F. Wilson, Esq., Weybridge, fine cut spikes of various Lilies.

RHODODENDRONS AND THEIR CULTURE.

I was disappointed that in the article thus entitled, which appeared in page 409, no mention was made for out-door culture of what I know as Rhododendron caucasicum, which is dwarf, hardy, the first to flower, and has flowers streaked with rose while in the bud state, delicate sulphur-coloured when blown. Nor is mention made of the double, which is equally hardy, large, and handsome in stem and trusses.

These, with numerous fine varieties, thrive admirably here in the north-east of Scotland, at an elevation of 700 feet above the sea level.

Then, for pot culture, how can your contributor omit R. Edgworthii and Nuttallii, one so handsome a plant, the other redeeming the rough coarseness of its leaf, and rather crabbed growth, by the size, beauty, and delicious fragrance of its flowers?—H. C. J.

LICHENS ON FRUIT TREES.

THE espalier Apple and Pear trees here, both in their trunks and branches, I found on my arrival, two years ago last April, "as green as grass." I bought a mason's whitewashing brush, and having slaked some lime I made a thickish wash of it, added a little soot, and laid on the wash over the lichens in winter. The trees are perfectly clean, and I have seen no renewal of the lichens.

I have drained all three of my gardens 3 feet 6 inches deep. I believe lichens betoken a want of drainage, but also that they may be attributed to other causes. They harbour insect pests, and can no more be beneficial to a tree than scurf on the skin to an animal. The skin is the second lung, and performs the office of leaves till these are formed. Stoppage of the pores of the skin cannot be advantageous to health. Attention must be paid by arboriculturists to the skin and leaves of trees, and as much attention should be paid to the roots as to the branches. We want gardeners to be as "well up" in the roots as in the branches.—W. F. RADCLIFFE, *Okeford Fitzpaine*.

NAMING PLANTS IN PUBLIC GARDENS.

THE spirited and artistic manner in which the public gardens in the neighbourhood of the metropolis are managed, at once preclaims the desire of those who have their direction to provide the public with the means of pleasure and gratification of the purest and most healthy nature; and the thousands who escape the smoke and din of city life to avail themselves of spare moments to breathe the breath of flowers, return invigorated to their multifarious duties, their mind provided with a fresh train of thought, which must, perhaps imperceptibly, exert a beneficial influence over their nature. As regards the town population, the objects of public gardens are to a great extent answered. These visitors come to enjoy a feast of beauty, and their presence in turn gives energy and pleasure to the promoters. Thus the enjoyment is reciprocal.

There is another and an important class of visitors, who from the very extremity of the kingdom, and even beyond its limits, periodically visit public gardens near London, but with an object different from that of their city brethren. A mere feast of flowers is not the primary object of their visit, these they leave at home in abundance. Public gardens are by this class of visitors regarded as standards of excellence, and they are anxious to see how near their own approach this standard; or such gardens are looked upon as experimental gardens, where objects are examined with a critical eye, their adaptations and qualities duly noted, and conclusions arrived at as to the desirability of the plants for the home plots. These, in numbers of cases, are so limited as not to admit of unproved novelties. Every bed is under the eye, and must be planted in confidence to give a good return. Viewed from this stand-point public gardens are not only establishments of public interest, but are emphatically institutions of public usefulness; and as the directors are evidently desirous of contributing to the public good, they would greatly enhance the interest of these gardens if the plants employed were legibly and correctly named. This omission is a drawback common to most of them. At the Crystal Palace, Hyde Park, Royal Horticultural Gardens, Battersea Park, &c., the public cannot learn the names of the plants employed except by going to a considerable amount of trouble. If the men who happen to be working on the spot are appealed to for information, it is ten to one if they are able to give the names promptly and correctly, and as long as the authorities withhold from the public the means of acquiring the names in a proper and legitimate manner, so long will these men be troubled and hindered in their work by the queries of visitors, who from curiosity or more solid motives are naturally anxious to know what they are looking at and admiring. The omission is certainly inconvenient, and a remedy would, I am sure, be hailed with pleasure by thousands.

From a variety of considerations it might not be desirable to

have names appended to the plants all over the garden; but would it not be desirable to reserve a plot as a sort of garden of nomenclature, where a plant or two of every kind might have its name attached in a position accessible to all, and in such a manner that it would not be necessary to remove the label in order to read the name? This would be a feature in these establishments which would be attractive, interesting, and useful. This is the suggestion of a gentleman, a patron and lover of horticulture, who visits periodically the various public gardens for the purpose of acquiring information, and each time returns disappointed at his inability to acquire the names of many plants which he would be glad to know, and which he thinks ought to be provided. He reasonably only regards himself as the representative of many others similarly circumstanced, and thought the subject of sufficient importance to be mooted in the columns of THE JOURNAL OF HORTICULTURE.—J. W.

MAKING SKELETON BOUQUETS.

WHEN your leaves are dry enough to work handily, commence forming them into bouquets. Take the larger leaves and those with the longest stems and place them in a sort of semicircle on a sheet of plate paper; or, if you wish to form them into a sort of wreath, commence near the top of the sheet and work in a circle, bringing the sides of the wreath together at the bottom and fastening them in a knot of blue or straw-coloured ribbon. These colours look best with the snowy lacework of the leaves, though some might prefer green. If a wreath is formed, a small picture may be placed in the centre. A Rose, in bright colours, with a few buds, and a growth of vivid green leaves, would look beautifully if surrounded by the frosty network of the skeletonised leaves. The leaves, I should have said before, may be fastened to the paper by just touching the backs of them where they join the stem with a drop of colourless glue. They will overlap each other and hide all traces of their being glued. Of course, they should not be laid on flat, one over another, as such an arrangement would spoil the effect. They must be disposed as naturally as possible. Nature is always an excellent guide in these matters, and the more closely we imitate her the better we shall succeed in our experiments. Some of the leaves should be curled over the fingers and then fastened along the middle of the wreath, or in the central part of the foreground of the bouquet. They will lie up among the others, and their graceful curl will relieve the whole collection from any prim, stiff appearance, and make it look airy and light. If a bouquet is made, it should be rounded-up towards the middle in front like a bouquet of flowers. You will understand what I mean better, probably, if you imagine a bouquet cut in halves, and one-half laid on a sheet of paper before you. You will observe that it is rounded from the side. If a bouquet is made, leave several long stems of nearly an equal length below the leaves, and glue on a knot of narrow ribbon as though that held the cluster together.

A nice case for these wreaths or bouquets is made as follows:—Take four pieces of thin light board, and make a box about 6 inches deep. Colour the outside with some dark colour, and line the inside with smooth white paper. The box, of course, will be made to correspond to the size of the sheet on which you have made your wreath. The sheet should fit in nicely and smoothly, and it will, if you are careful and particular in making the box. I ought to have mentioned that a groove should be cut in the box to admit the glass in front.

Now, when you have your pictures fitted nicely in the box, or, perhaps, it should more properly be called a frame, if it looks unfinished (and very likely it will), you must go to work and make some sort of a flat frame, the inner edge to be of the same size as the deep or box frame, which can be fitted on over the latter with strong glue. Make it neatly, and give it a colouring of umber, nitric acid, or some such stain. Then exercise your taste in forming pretty figures on it with seeds of different plants. If you place a row along the outer and inner edges, it will look very pretty, and if Peas or Beans are used they will give it the appearance of being "beaded," as carpenters term it. Beans or Peas must be split before being used, and coloured after being put on.

Groups of Burs look extremely well; besides, they need no colouring. They are of fine shape, and when placed in clusters have a decided resemblance to some kinds of flowers. You can invent many ways to make your frame very ornamental,

and your own judgment and taste will guide you in the work, and create something that will not cast a disagreeable contrast on the beautiful, frost-like, airy ghosts of summer's leaves inside the case.—E. G. REXFORD.

THE LILY OF THE VALLEY.

EVERYONE fond of flowers admires this graceful and pleasing little harbinger of summer. Despite the rage for exotic plants, the Lily of the Valley remains a favourite, and many thousand spikes of its flowers are disposed of in Covent Garden Market; indeed, the flowers of no other British plant, probably, are in greater demand.

In several parts of the woods here, the Lily of the Valley grows very freely, and the places where it succeeds best seem to be little better than beds of very fine sand. Some of these spots are overshadowed by Oak trees, which afford protection from the sun during the heat of summer, and generally there grows amongst the plants such a close covering of *Pteris aquilina*, that it appears when in full leaf sufficient to choke, if not to entirely kill them. I have had this impression, but when visiting in the following May the places where the Lily of the Valley was growing, I found it again in full force. Its leaves soon die down when exposed to the heat of summer, and I have never seen it in a wild state so strong as it is when grown in shady places in gardens, especially when not disturbed for years.

It is generally very impatient of removal, and often some years will elapse before it acquires in a new position the same degree of strength which it exhibits when grown in good sound soil in a shady situation. I have often seen it doing well in beds at the back of a high wall; the north side answers best, as the plant does not seem to enjoy full exposure to the sun's rays. It might be asked, Why not at once imitate its native habitat during the summer months? I do not perceive the propriety of doing so, except to a limited extent near some fernery or rockery adjoining pleasure grounds.—G. DAWSON, *Chilworth, Romsey*.

VIOLA CORNUTA, AND ITS FAILURE IN DRY SEASONS.

Most of our ornamental plants are from climates which are warmer and more sunny than our own, and where the weather or locality is cold and sunless the result which they afford cannot be satisfactory; but we also cultivate a class of plants from moister climates, and where rain instead of sunshine prevails they flourish. Thus, whatever be the character of the weather in England, we can always enjoy something, and the most adverse season never passes away without its proving favourable to certain plants; and if that which is successful be only recently introduced, we are apt in our enthusiasm to give it a higher degree of importance than it deserves, and the reverse if the contrary should be the case. The more popular the plant, too, the greater the outcry when it fails.

Now I expect to hear complaints against a plant which has been highly lauded during the last two years, and especially if the summer should be dry and hot. *Viola cornuta* was in everyone's mouth as a plant of the first merit, and there was some controversy as to who had first introduced it as a bedding plant. Without giving any opinion on this point, I anticipate that after a dry summer it will be ejected from most places where water is scarce, and that it will be exclaimed against more than it ought to be. Without wishing to disparage this plant, I have always maintained that it is better suited to a moist season or situation than to a dry one, and as during the past two years there has been no lack of rain in the growing summer months, it has prospered much better than it may do in 1868. I anticipate its total failure this year in places where its planting-out was left until the usual bedding-out time arrived; for, like the *Cerastium*, it ought to be planted early in spring, or, which is better, in the autumn. Mine were all planted at that time, and were in full bloom when the bedding *Pelargoniums* and other plants were turned out; but even with the advantage of being established six months or more, dry weather begins to have an effect upon it, and I anticipate a short season for this plant, though during the previous two years it continued longer in bloom.

Now, we have no reason to find fault with this. No plant is so constituted as to prosper alike in all seasons, and we must regulate our planting by what we know of our soils, and by what we can guess of the coming season. On the average of

seasons it will be found that this plant will be in better condition when the rainfall is abundant than where scanty, and the north of England and Scotland would seem to be its home. Let us not discard it altogether, for although it will not endure for successive weeks the bright hot sunshine which makes the *Pelargonium* flourish, it has its time and place.—J. ROBINSON.

SCARLET FLOWERS.

AMONG all the colours that blooms assume, none are less associated with fragrance than scarlet. We cannot at present recollect a bright scarlet blossom that is sweet-scented—yet no other colour among flowers is more admired and sought after. Scarlet prevails among *Balsamina*, *Euphorbia*, *Pelargonium*, *Poppy*, *Salvia*, *Bouvardia*, and *Verbena*, yet none of the scarlets are of sweet perfumes. Some of the light-coloured *Balsams* and *Verbenas* are sweet-scented, but none of the scarlets are. The common Sage, with blue blooms, is odoriferous both in flower and foliage; but the scarlet *Salvia* are devoid of smell. None of the sweet-scented-leaved *Pelargoniums* have scarlet blooms, and none of the scarlet bloomers have sweet scent of leaves nor of blooms. Some of the white-margined *Poppies* have pleasant odours; but the British scarlets are not sweet-scented. The British white-blooming Hawthorn is of the most delightful fragrance; the scarlet-flowering has no smell. Some of the *Honeysuckles* are sweetly perfumed, but the *Scarlet Trumpet* is scentless.

All the Beans with light blossoms have pleasant odours, but not the *Scarlet Runner*. The Rose gives fragrance to all its colours, but the *Gloire de Rosemère*, which approaches nearest to scarlet, is as scentless as the *Yellow Harrison*. The florists' varieties of *Tulip* have a gentle odour, but the scarlet has as little perfume as the yellow. Many of the flowering shrubs have very fragrant blossoms; but the scarlet *Cydonia* has no smell. *Carnations* and *Gilliflowers* have some blooms approaching to scarlet—they are fragrant.

There are plants that bear scarlet blooms or scarlet fruits, suitable for every department of ornamental gardening, and every department should be adorned with scarlet, or a near representation thereof, for no decorations are complete without it. In glass houses there are *Bouvardias*, *Cupheas*, *Euphorbias*, *Alonsoas*, *Pelargonium*, *Gilliflower*, *Leschenaultia*, *Manettia*, *Salvias*, with scarlet blooms, and *Poinsettia* with scarlet bracts, and *Ardisia* with scarlet berries. For out-door flower beds, *Cannas*, *Balsams*, *Carnations*, *Gilliflowers*, *Cacalia*, *Lobelia cardinalis*, *Lychnis*, *Bouvardias*, *Pelargoniums*, *Cupheas*, *Salvias*, *Gladiolus*, *Tulips*, *Verbenas*, *Zinnias*, &c.

For Climbers, *Scarlet Trumpet Honeysuckle*, *Manettia*, *Cypress vine*, *Scarlet Runner Bean*, &c. Amongst trees, *Cereis canadensis*, gives a representation in blooms in early spring, and *Scarlet Oak* and *Red Maple*, with leaves in autumn. Among Shrubs, *Sorbus* and deciduous *Enonymus*, and *Red Snowberry*, with fruits all fall and partly through the winter. *Cydonia*, with blooms in early spring, and *Tartarian Honeysuckle*, *Sweet Briars*, &c., with fruits through the autumn. In those different departments the sight can be feasted upon scarlet all the year round; and the scent can feast upon the fragrance of very many other kinds of plants.

Many of our enterprising florists and seedsmen have given a fresh impulse to the love of floriculture, with their finely illustrated catalogues, within the past few years. They would even be more intelligible if they had abbreviations of the colours of all species and varieties, and then the purchasers could select, sow, and plant more knowingly, to adorn their parterres with all colours, and especially dazzling scarlet.—WALTER ELDER (*American Gardener's Monthly*).

A QUICK GROWTH.—The new early Peas, *Ringleader*, sown on the 12th of February, were last week harvested—fully ripe, at Messrs. Sutton's Farm, London Road, Reading.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE ground is now in good order for the reception of autumn and winter crops, and no delay should occur in planting out a quantity of the most forward *Brussels Sprouts*, *Savoy*, and *Broccoli*. Those who have their first Peas cleared off the ground will be so far fortunate, but there are not many places where there is ground enough to enable the gardener to have only one crop on the ground at once. *Broccoli*, large breadths of the

winter and spring sorts should now be planted out as vacant pieces of ground fall in. *Celery*, now is a good time to put in the first main crop. A few trenches will have been previously planted. To save ground it is recommended to plant it all in beds about 4 feet wide, with ridges of the same width between, sowing a row of Peas along the centre of the ridge, and using the trench for Lettuces, &c., before it is wanted for *Celery*. The beds intended for late *Celery* are narrower, should be manured as soon as possible in the spring, and should be planted with early Potatoes to succeed those in frames. The trenches should be formed with a high and low side resembling a turf pit, strong stakes to be laid across from side to side, upon which common hurdles wattled with spruce fir branches are to be drawn up and down according to the weather. This method may be useful to the amateur who is fond of Peas and *Celery*, and has but little ground at his command. *Cauliflowers*, *Endive*, and other autumnal succession crops, to be planted out at regular intervals; and see that there are no plants left to run to seed among beds of Carrots, Salsafy, Scorzonera, Skirret, and Chicory, all of which are liable to throw up seedstalks.

FRUIT GARDEN.

The routine of thinning and tying-in the summer growth, and the destruction of insects, must still be attended to. All stone fruit trees may now be budded, spring grafts looked over, the clay broken, and the bandages loosened. The grafts must have stakes put to them, or they will be broken off the first windy day. Those persons who have Vines trained on a cottage or in other parts of the garden should examine and carefully regulate the branches, taking care to retain no more young wood and fruit-bearing shoots than the Vines are capable of supporting and bringing to maturity. The fruit-bearing branches, if it has not already been done, should now have their tops pinched off two eyes above the bunch, and the others may be stopped in the same manner when they have reached about 20 inches in length. After this stopping, at most of the eyes the Vines will in all probability throw out laterals, which should be nipped off immediately above the first joint, taking care, however, not to injure it for fear of prematurely starting the bud at the base. No more shoots should be allowed to remain than are necessary to cover the space there may be for training them. It is always better to keep Vines thin and open than to crowd the branches together, for loading the plant with a superabundance of wood only serves to weaken it and rob the fruit of much of its nourishment.

FLOWER GARDEN.

From the beginning to the middle of July is the best time in the year to increase Roses from layers. The shoots are less brittle now, and on that account easier to handle than when they are ripe. There is also much time saved by summer-layering, as the layers will be rooted and fit to be bedded-out in nursery rows next November. Besides, there need be no cold fingers as when the work is done in February or March. Those who intend to grow Roses in pots for exhibition or private use, and for early forcing, should have their plants worked on some of the free-growing China Roses. These are now throwing up from near the bottom strong suckers or shoots, which may be layered for stocks and budded immediately. The height at which these should be budded is a matter of taste. A few standard Roses are very useful in the conservatory early in spring, and their ugly stems can always be hidden by other plants. For exhibition, on the other hand, standards will not do at all, unless they are exceedingly well managed, and rather dwarf than otherwise. For mere pot culture stocks of the common China Rose are as good as any. The Bourraulte, however, possessing the softness and excitability of the Chinas with the hardiness of the Ayrshire, are considered by growers to be the best stocks for general purposes. Any variety of this section will answer; Drummond's Thornless is one of them. In preparing the shoots for layering be very particular in picking out all the buds below the places where the new buds are to be inserted. This will keep the stocks always free from suckers and side shoots—not, however, unless the shoots are of this year's growth, as we have no power over older shoots, which are already coated over with a layer of organisable matter that can throw out buds anywhere. Early Tulips, Hyacinths, Narcissus, &c., may now be taken up, dried, and cleaned in a dry shed, and be put up in the seed room till planting-out time. To have beautiful little plants of *Chrysanthemum* with large heads of flowers, you must begin now by selecting the strongest shoots on the plants growing in the open ground, draw them out along the ground, and at 3 or

4 inches from the top peg them down. They will soon turn up their points again, and in about a fortnight or three weeks you may sink pots full of rich mould under the beds, and layer these shoots, letting the bend down near the bottom of the pot. The pots will soon be full of roots, and on a damp evening you can cut off the shoots and remove your plants to a close frame.

GREENHOUSE AND CONSERVATORY.

Greenhouse plants will now do well enough with the usual routine of watering, syringing in the evening, tying, staking, and training, as may be requisite. As all but the very best specimens are now removed from this house you will have room to introduce annuals, placing three or four of them in large pots; with a little care they will be useful for the conservatory. There is no scarcity of flowers in the conservatory now. The usual routine of training the climbers and keeping the other plants in order, together with neatness, is all that is immediately wanted; but keep a good eye to your winter stock. Camellias that have formed their flower buds may now be potted; those of them that are to flower early should be kept in-doors all summer, but the spring-flowering ones may be turned out. Anne Boleyn Pinks for forcing ought now to be in a forward state, and if they show symptoms of flowering pinch off the stems as they appear. This is the proper time to attend diligently to such plants as will flower from October to May.

STOVE.

If any established stove plants require another shift this summer let it be given soon, but avoid shifting large specimens so late if you can; rather encourage them with a little liquid manure occasionally. Young plants may be potted as they may require for the next two months. Do not neglect to make cuttings of *Justicias*, *Clerodendrons*, and similar useful plants early in July for flowering next year. These will form beautiful plants before the end of October. *Pentas carnea* belongs to this class; it is a very useful plant in winter, and may be had in flower all the year round. Air, moisture, and cleanliness, as usual, are requisite.

PITS AND FRAMES.

These are the best places to grow the most choice sorts of greenhouse plants in summer. Heaths that have not yet flowered should not have any shade over the glass, as they set their flower buds much better in the full sun. Syringe all the plants here every evening, so as to preserve a cool refreshing temperature all night.—W. KEANE.

DOINGS OF THE LAST WEEK.

The work has to a great extent been of a routine character, and besides Grape-thinning, potting, &c., the great aim has been to keep everything growing with as little watering as possible.

KITCHEN GARDEN.

Some fine rows of Peas coming into bloom we were obliged to water, and then mulch along the sides to keep the moisture in, as the foliage was becoming of a light slaty colour, and the blossom was refusing to set. A plantation of *Cauliflowers*, our third succession, was also changing colour, and we were afraid they would knot for bloom too soon, and come to little, and these we watered, then covered the ground with dry litter, and shook a little of the cleanest over the leaves to moderate the force of the sun's rays. Strawberries in pots, which we intended planting, but could not, after being watered were sprinkled over with litter rather more thickly to keep the heat from evaporating the moisture too soon. Having a tank to clean out, and at no great distance from the *Celery*-bed trenches, we planted several beds, raising the plants with large balls, and turning them out into well-aired soil pretty liberally supplied with rotten dung. After watering them well we scattered litter over the plants as well as the beds, and the hottest sun seemed to have little effect on the plants. A brisk wind or a heavy shower will send the litter off the plants, and it will do no harm lying on the surface. Finding that Turnips would be bitter where fully exposed, unless they had more water than we could give them, we likewise afforded them a little shade by a similar means. Such a mode of slightly sprinkling with litter answers better than the shade of a mat, &c., for common purposes, not so well, of course, as tiffany would do; but then that, however used, will tell in the garden expenses.

For a long time we have had little to do with shading material

for houses, but for these nothing answers better than a screen of white tiffany or other light textile material, fixed with rings inside during the summer months. It will thus take off the force of the sun's rays, and will not make the houses too dark in a dull day. The lessening of evaporation from the foliage by any such means enables the plants to withstand hot weather longer without watering. Four years ago we were obliged to cover up many plants in a shady place; but though we are obliged to be moderate in watering, still it would be some weeks before we should be reduced to such a strait as that, and such summers often do good in leading us to contrive how to save water that otherwise would run to waste. With more care in thus saving the water in large reservoirs, a force-pump to raise the water to an elevated cistern, and connecting pipes with our tanks, we feel we could be almost as independent as the gardener not far from a river, who had, nevertheless, most of the water to carry. With a cistern high enough we could use a hose at once.

In sowing Carrots, Turnips, Beans, Lettuces, &c. in such weather, we find it is a useful plan to draw the drills, water them before sowing, cover in the usual way, and then slightly litter the ground before the seeds are up, when the litter can be moved from the rows to prevent the young plants becoming drawn and weakly. If such weather continue it is better to depend for salads on Lettuces sown, rather than on those transplanted, and much watering is thus saved, as the sown plant sends its roots deep and is nearly independent of watering even in dry weather. In fact, but for scarcity of ground, we would throughout the summer prefer sowing all the Lettuce tribe thinly.

Far too often there is a scarcity of ground in the kitchen garden, and huge unwieldy lawns that might in many cases be better turned into park scenery. A gentleman is content to receive, with many drawbacks, from £1 to £2 per acre for his agricultural land, which, after cleaning and fallowing, seldom produces more than one crop in the year, and yet he expects numerous crops in the season from similar land because it is called a garden instead of a field. For ourselves it was quite a change to see this summer a piece of ridged-up bare ground on which Raspberries had grown, and which were stubbed-up after a succession was secured. But for pressing matters that ground would not have been idle, and it is now cropped with Peas at wide intervals, with half a dozen rows of Winter Greens, the most forward, between the rows of Peas.

Cropping.—When many crops are taken from the land, and several are coming on at the same time, the produce individually will not be so good as when the land bears only one crop at a time. For instance, it cannot be supposed that Broccoli planted between rows of Peas or Potatoes will yield such magnificent heads in spring as that which has had the ground wholly to itself, and the plants have been no closer than 30 inches on the square from each other. Very good heads for the table can be had from the close rotation, and the varied simultaneous system of cropping; but that is not the plan to have large individual heads that would require almost a basket for each.

Do not let it be supposed that we advocate large walled-in gardens as a rule, for in many cases they are as much a mistake as large pleasure grounds with insufficient labour to keep them well, believing as we do, that ten poles of a lawn that cannot be improved, will be more satisfactory than ten acres that have merely a semblance of keeping. On the other hand, we know several places where the kitchen garden is too small, where fruit and vegetables, and plenty of them for a large establishment are expected from something like an acre of ground. Now, in such cases, it is necessary either that the garden outside the walls should be enlarged, or that the root and other rough crops should be grown in the field, and the garden thus relieved of such continuous cropping. In some of these places we have known a free succession of gardeners, able, intelligent men; and the employers, kind-hearted and considerate, would much rather they had remained, were satisfied with their conduct, and would in several cases have held out extra remuneration for them to remain, knowing well that if there are advantages at times in changing, there is more likely, for a time, at least, to be disadvantages, as it will be some time before a new man gets acquainted with the place, and with the peculiar wishes of the family and establishment. It is very pleasant to hear a gentleman say, "I am so sorry that Mr. A. would leave me. He was such a good, industrious, faithful servant; but I hope he will get on well wherever he

settles. I shall always esteem him, &c." Now, the secret of leaving, to our knowledge, in a number of such cases, was the smallness of the garden. The gardener saw that with the same ground the demands every year were increasing, and he felt that the time would come when inability to meet the growing demand might lead to disappointment; and as hints as to increased room, or growing some of the crops in the field passed unheeded, he preferred leaving instead of encountering any unpleasantness from such a cause. In the whole of such cases it would have been easy to have taken from a field or park outside the walls the ground that would have been necessary, surrounding it with a Privet hedge, a wire fence, or a picturesque bank of Laurels, &c.; or to have made arrangements that beyond the earlier crops the bulk of the root crops should have been grown in a field, and so grown they are generally sweeter and better than when cultivated long in an old kitchen garden. A huge walled garden may be a huge mistake. A very small kitchen garden may also be a mistake, and fruitful of disappointment and unpleasantness.

FRUIT GARDEN.

Air-giving.—To lessen the necessity of so much watering, we afforded little front air, but gave it at night and early in the morning. We are not yet fully convinced, in general, how gradually a house rises in temperature with air early given, and with the heated air outside partially shut out. A Peninsular officer, who, bold among the bold, had also a keen sense of the comfortable, told us how after a hot march in Spain, he cooled his wine by hanging the bottle in a worsted stocking full in the sun, and had a lad to stand by and keep the stocking moist. The evaporation from the stocking cooled the bottle. He also contended that the true plan for keeping rooms cool in summer, was to keep the heated air of the day from entering. After the evening and early morning the windows were kept close and shaded. A glass corridor was likewise kept shut, the doors and windows of rooms connected with it also shut and shaded, and though outside the temperature was melting, that of the rooms resembled the coolness of the passages of an ice house. This furnished proofs on a large scale of what we have several times alluded to, that confined air is one of the best non-conductors of heat. Could the corridor have been air-proof, the coolness of the rooms in summer and their warmth in winter would have been more thoroughly secured.

We could not carry out such an idea in our glass houses without double glass; but even for the saving of water we gave less air than we otherwise would have done, and we observed no ill effects until about the middle of the week we noticed some leaves of Peaches coloured by the attacks of *red spider* in the orchard house, though previously quite free from it, notwithstanding the heat and our unwillingness to syringe, as we otherwise would have done freely, on account of the water not being quite to our mind. We syringed with soot water, followed with weak clear soft-soap water next day, and then we did what we should have done a month ago—daubed the open places of the wall with a paint of sulphur and soft soap. We have examined a number of the leaves to-day with a glass, and though finding some dead, we found none alive. We shall, therefore, use clear soot water in syringing, and syringe a little more than we have done; but the sulphur fumes given off by the wall where daubed in a clear sun will be one of the best means for settling those there, and keeping other spiders from trespassing. How suddenly such vexations come! A couple of days previously we could not see a discoloured leaf. We are sorry to say that the red spider seems bent on attacking Dwarf Kidney Beans out of doors. Some of these we pulled up and burned, as they were near trees that might soon be affected. Such scorching weather is just the delight of this insect. Weak soap water and clear soot water do much to keep it away. Dampening the floors has not kept it quite out of the orchard house, and now the insect must be overcome, or farewell to fine-flavoured fruit.

ORNAMENTAL DEPARTMENT.

Much the same as last week. Used little water in beds for a week, only when plants were suffering. As a rule they are doing well, and rooting freely, only needing a drizzling cloudy day or two to give them a chance to push out their dormant energies.

We have many plants, as Antirrhinums, Everlastings, and even Sweet Peas, to plant out; and they must go out and be watered if we have no rain, though we would have preferred the ground to have been damper and cooler before turning them out.

Now is a good time to mark all Pinks, if the pipings or cut-

tings are not taken off directly. Cuttings of Pansies may now be inserted under glass in a shady place, and air given at night. Plants from seed sown now will bloom in the autumn. Hollyhocks and Dahlias need plenty of watering and mulching where this dry weather prevails. Several beds in which we mean the brown Coleus to be a prominent feature we have not yet planted out; but the strong plants in pots are freely exposed, and we hope they will not become dirty brown with us this season.

In the flower garden as a whole we are becoming reconciled to feathered intruders; only that for the sake of the families of young pheasants, rather too young to take themselves farther afield, we cannot have a beat for the rabbits, which are rather vexing us by eating close to the ground lines and edgings of Lobelia. Without netting it is difficult to know what to do. We strewed with a trowel on each side of such rows a line of fresh lime and soot, and then sprinkled these lines sparingly, without touching the plants, with flowers of sulphur. For four nights the Lobelia has been let alone by the intruders. The fumes given off seem to be not to their taste. We expect that when heavy rains come the remedy will have lost its power. At present the application has been useful, and the fumes are rather strong. The plants are growing strongly, and though later than desirable, would yet do well if let alone, and not cropped down again.

Much time has been taken up in arranging corridors, conservatories, &c.—a matter more difficult than it used to be, as the roofs of our fruit houses are too thickly covered to permit after this season of growing much beneath them. For the same reason we must keep many of the Azaleas in a place by themselves in the conservatory, and syringe and keep them closer there, whilst flowering plants at the other end will have more air. These matters are more easily managed when such plants after flowering can be put in a house by themselves; but many must do what they can when they cannot accomplish what they would.—R. F.

COVENT GARDEN MARKET.—JUNE 21.

We have experienced a large increase in our supplies since last week, and consequently a great reduction has taken place in the price of some articles, and especially of forced fruits. Grapes and Pines are much in excess of our requirements, and there are very few Peaches and Nectarines that come up to a good standard. Some good Shaw Potatoes are now coming in from Kent, and in many places the new crop of Potatoes will soon be ready for lifting. Prices range from 4s. to 6s. per bushel.

By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

Books (Atlas).—If you wish only to manage a small plot, "How to Farm Two Acres Profitably" will suit you. You can have it free by post from our office if you enclose fourteen postage stamps with your address.

ROYAL HORTICULTURAL SOCIETY'S LEICESTER SHOW (H. T.).—Apply to Mr. Eyles, Royal Horticultural Society, South Kensington, London, W.

GOLDEN-LEAVED PELARGONIUMS AT THE ROYAL HORTICULTURAL SOCIETY'S SHOW.—Golden Emperor which received the first prize as the best Golden-leaved variety not in commerce, was exhibited by Messrs. Saltmarsh & Son, of Chelmsford, and not by Messrs. Downie & Co., as stated in page 438. The report there given was originally correct, but finding by the official prize list that the variety referred to was ascribed to Messrs. Downie & Co., and thinking that some mistake had occurred in the cards (and of such we have met with several instances lately), that which was correct was altered to that which was wrong.

RENNET (REINETTE) APPLE (Alpha).—Your inquiry why that name was applied to various Apples is best answered by the following quotation from Drayton's Polyblon:—"When a Pepin is planted (grafted), on a Pepin stock, the fruit growing thereon is called a *Rennet*, a most delicious fruit, as both by sire and dam are well descended." We quote the extract from old Fuller. *Reinette*, literally, is a little queen.

ERADICATING THISTLES (—).—The best way to eradicate Thistles in pasture land is to ent them with a spud a few inches below the surface. It should be done early in June and again in August. The best spud is one to which is attached a box for salt, and on the spud being thrust into the ground and withdrawn salt is deposited over the root. The root then seldom recovers. The Thistles may be kept under by cutting them with a scythe close to the ground three times a year—namely, at the end of May or early in June, in the middle of July, and at the end of August.

CUCUMBERS AND LETTUCES AT CHRISTMAS (Idem).—You may have Cucumbers at Christmas if you have a small house or pit which can be heated to 60° or 65° at night, and 70° or 75° by day. There must be a bed for bottom heat in which the plants can be planted. No great expense need be incurred in the growth of water Cucumbers. Lettuces may be had at Christmas by lifting a number of plants in October or November with good balls of earth, and planting them in a cool house, pit, or frame. Give a good watering after planting, then water sparingly, and give plenty of air and protection from frost.

CAMELIAS NOT FLOWERING (A. H. Holden).—The temperature you name is much too high for Camellias. One of from 60° to 75° is certainly desirable for a time after the flowering, or from March to the end of June, but after that the plants would be better of a cool house where there is no artificial heat. We think that the atmosphere is much too dry, and the plants not sufficiently supplied with water, and that therefore the leaves fall off. Keep the plants cooler and give a plentiful supply of water. It will be enough if they are kept from frost in winter. A few degrees of frost will be far better than a high temperature at that season.

BUDGING APPLE AND PEAR TREES (A. Norrie).—It is an excellent practice to bud Apple and Pear stocks on which grafts have failed in the spring. The end of the present month and early in July would be a good time to bud, and it may be practised with Plums and Cherries as well. The Manetti Rose is a free-growing kind, extensively used as a stock for grafting and budding Roses on for dwarfs. It may be had of almost all nurserymen. Any nurseryman would procure plants for you. The present is not a suitable time unless they are in pots.

PELARGONIUM AND GERANIUM (Idem).—What are frequently, but incorrectly, termed Geraniums are Pelargoniums; and if you see the same plants under both heads the only distinction is, that in one case the proper generic name is applied, in the other the improper but customary one. The genus *Geranium* has been divided into three genera—*Geranium*, *Pelargonium*, and *Erodium*. They all belong to the natural order *Geraniaceae*. *Pelargonium* is characterised by having usually seven stamens, and unequal-sized petals; *Geranium*, by having ten stamens, and equal-sized petals; and *Erodium*, by having five fertile anthers usually.

PELARGONIUM CULTURE (Idem).—When your Pelargoniums are done flowering set them out of doors in a sunny place, and then cut them well back, and they will grow dwarf and stubby. If you have plenty of room do not prune back so much, but bend down the stems, and shoots will come from each joint.

LAWN (J. D.).—Your lawn must be very wet to encourage the growth of moss at this season. A dressing of superphosphate of lime may be given, but we would not apply it until the ground is wet and rain likely to follow soon after the dressing.

STRAWBERRY BEDS (Idem).—We have had very productive beds of Strawberries at the end of six years, but of late we have not kept our beds beyond the third or fourth year. We break up a number of beds every year and make a new plantation. We have, therefore, no lack of supply, as we find the seasons have a great influence on the crop. With us the plants produce the best crop in the second year, and in very rich ground we have found the crop greater in the third than in the two preceding seasons. We plant early in August, putting a number in beds rather thickly, and these plants are very useful for filling up any blanks in the new plantations; and moved with balls they are excellent for new plantations. March is a good time to plant those put in rather thickly in beds in August.

PEARS BLACKENED AND FALLING (Lemon Buff).—The Pear sent us is destroyed by some insect entering by the eye of the fruit and completely destroying the interior. The specimen was so smashed in passing through the post office, that we could not detect the insect causing the mischief. We have many young fruit turning black as yours are, and falling, chiefly owing to imperfect fecundation. The Pears which thus fall are seedless.

SOWING SAXIFRAGE SEED (King Theodore).—Now is a good time to sow Saxifrage seed. Well drain the pot or pan—indeed fill it to within an inch of the rim with pieces of sandstone, or grit, and corks; then to the rim with a compost of turfy peat, sandy fibrous loam, and silver sand in equal quantities. Make the soil very fine, level the surface, sow the seed rather thickly, and give the least possible covering of very fine soil. Place the pot in a shady place, and cover it with a bell or hand-glass, keeping the surface moist. When the surface becomes green give air by tilting the glass, admitting more as the plants grow, and when of a size fit to handle prick them off in pans prepared in the same manner as the seed pot. Protect with a frame during the winter, giving an abundance of air in mild weather and a little at all times. The seed may be procured of any seedsman, and plants obtained from the principal nurserymen. We cannot recommend one in particular.

SOWING PELARGONIUM SEED (Idem).—The seed should be sown as soon

as it is ripe, any time from now up to October, in pots or pans placed near the glass in a greenhouse. There is but one mode of cross-fertilising—that is, by taking the pollen from one species or variety and applying it to the stigma of another. The pollen is best applied with a camel's hair pencil.

CHERRIES FALLING (*Cliftonensis*).—The fruit sent has not stoned, and that is the cause of its falling. It is, of course, seedless. We think the reason is the aspect, and consider the Downton variety succeeds better as a standard than against a wall with a north aspect, which, however good for the Morello, does not answer for the Downton. It succeeds and well deserves a place against an east wall.

VARIOUS (*T. T.*).—We approve of most of your arrangements, but not of your proposed painting or dotting the glass with white lead, as it will make the roof permanently opaque, which is not desirable, particularly as your house receives no sun in winter. Instead of the white lead we would advise you to paint the glass inside, when the sun becomes powerful, with a mixture of Spanish white, brought to the consistency of paint by the addition of milk. It can be easily repeated if necessary, and may be washed off in autumn. You will not have room for more than a dozen plants in each house; and of stove plants we would have *Alocasia metallica*, *Anthurium scherzerianum*, *Croton variegatum*, *C. angustifolium*, *Maranta Veitchii*, *Caladium Chautini*, *Pandanus japonicus*, *variegatus*, *Dracena stricta*, *Gardenia citriodora*, *Ixora coccinea*, *Gesnera refulgens*, *Rondeletia speciosa major*. Climbers for roof—*Stephanotis floribunda*, which will cover the whole roof. For baskets—*Pothos argyrea*, *Pentas carnea*, and *Ascyanthus speciosus* and *pulchellus*. The back wall may be covered with *Cedrus discolor*. The plants may be occasionally syringed, but it is best to keep up a moist atmosphere and syringe in the evening only. For the cool division—*Acrophyllum venosum*, *Boronia Drummondii*, *Chorozema cordatum splendens*, *Crowea saligna major*, *Monochatum cuscutum*, *Pimelea Hendersoni*, *Genetyllis tulipifera*, *Kalanthes miniata grandiflora*, *Luculia gratissima*, *Nerium rubrum plenum*, *Imantophyllum miniatum*. Climbers—*Hoya carnea*, *Mandevilla suaveolens*, and *Mutisia decurrens*. For baskets—*Stanhopaea oculata*, *S. tigrina*, *Adiantum setulosum*, and *Platycentrum alceiforme*. The back wall may be covered with *Habenaria elegans*, or *Luculia gratissima*. The only means of knowing how much tobacco will be required for the fumigation of the house, is to fill it so that a plant cannot be seen from the outside through the glass. The fumigation should then cease, and not till then. Half a pound of tobacco leaf chopped or cut up roughly will be sufficient for one of the compartments. We do not know of any one likely to meet your wants with respect to a gas stove and boiler. *Gloxinia* leaves curl from being kept in too dry an atmosphere, and under too powerful a light. Shade from bright sun for a few hours during the hottest part of the day, and give water liberally, with a moist atmosphere. Variegated plants, as a rule, are impatient of syringing, and should therefore be well supplied with atmospheric moisture by sprinkling the paths, doors, walls, &c., two or three times a day. An occasional syringing will not do any harm providing air be given early, so as to have the foliage dry by the time the sun's rays fall on the plants. *Heliotropes* succeed well in a compost of turfy sandy loam two-thirds, and leaf mould one-third. *Voltaireanum*, *Etoile de Marseille*, and *peruvianum* are good sorts of *Heliotropes* for a wall. They should be repotted in spring when they are beginning to grow, and have a shift into a larger pot in June. The treatment is very simple: they merely require plenty of water when in free growth and flowering, and when at rest keep the soil rather dry, but not so much so as to cause the wood to shrivel and perish. After the plants have had a rest prune them as is required, and encourage growth by a moist atmosphere. Cocoa-nut refuse is still extensively used as a compost for Ferns. It is a good substitute for peat if mixed with loam, but is not suitable for *Heaths*, nor for the very delicate thread-like fibres of such plants as *Azaleas* until it is reduced by age to a black close mass, and then it answers quite as well as peat, silver sand being liberally added.

MISTLE-LEAVED ORANGE LOSING ITS LEAVES (*A. Subscriber*).—We would at once examine the drainage, and if bad rectify it. We would, if necessary, repot the plant in a compost of loam from turves taken from a pasture where the soil is a loam of good medium texture, but not very strong, paring off the turf 12 or 2 inches thick, and with the hand tearing it in pieces about an inch square. Remove most of the old soil, and pot rather firmly in the new compost. No manure need be used, but add one-fourth part of sandstone, broken to the size of a hazel nut, using the small pieces as well as the lumps. If convenient, place the plant in a house where there is a brisk heat of from 60 to 65 at night, and from 75° to 80° by day, a moist and rather close atmosphere being maintained, with shade from bright sun. Avoid saturating the soil until the roots are working freely, then water liberally. The plants should be syringed

overhead twice or thrice a-day. The head being very full of small shoots or twigs, thin it and cut them well in. When a good growth is made harden off by degrees. The manure water, if not too strong, would not cause the leaves to fall; but a powerful dose of liquid manure may have destroyed the roots, and so have caused the leaves to fall. Watering with liquid manure would conduce rather to growth than to fruitfulness, and we think the barrenness not attributable to a want of sufficient support. The reverse would be the case.

HEADING-BACK A PEACH TREE (*A. Subscriber*).—We do not see what you will gain by heading-back to B, unless you have shoots on the lowest horizontal branches that could be trained in place of those cut away. If you cut off the head of the tree at B, and have no shoot near B on the side branches which could be trained as leader, we think you will lose the head entirely, as you cannot expect shoots from a branch 7 inches in girth, and it is likely gum would follow cutting it, if not the dying-back of the stem below the cut. We presume you have enough side shoots; in that case leave the tree as it is, and by closely stopping the shoots and laterals on the branches between A, A, the sap will be diverted into the lowest side branches, and by not stopping them you may renew them by training in a well-disposed shoot in place of the weak side branches.

PEACH-TREE LEAVES BLISTERED (*Idem*).—The blistering of Peach-tree leaves is caused by cold, especially when preceded by a period of warmth, and is very prevalent this season, the days being very bright and hot, and the nights cold though not remarkably frosty. There is no remedy, but the evil may be prevented by affording a warm covering. Tiffany would be a much better protecting material than netting. No. 3 tiffany would be equal to canvas, and is a very good material. It would repay the cost. Tiffany when used as netting must not be left over the trees constantly, but be drawn up in fine mild days and let down at night. On cold days the covering may remain over the trees.

SCARLET GEM MELON PLANT FASCICATED (*J. Fleming*).—It is evidently a case of fasciation, and one of the most interesting specimens of it which we have seen. What are the circumstances under which the plant has been grown?

VINE LEAVES WARTED (*J. M.*).—The Vine most likely will grow out of the warts on the leaves. The warts are produced by a rather moist atmosphere, and too much moisture at the roots, and the leaves cannot part freely with the moisture by evaporation. More air and less moisture are the best remedies. The Black Hamburgh in this respect is a weaker Vine than the Muscat of Alexandria.

VINE BLOSSOM SCORCHED (*Black Hambro*).—In such a case as yours we would open the ends of your groundinery. We would prefer doing this to opening the roof, as the heated air would freely escape at the ends in such short lengths. We cannot account for the scorching with all the air on at the sides, but in hot days we certainly would like to have the ends to move, especially the half next the ridge.

ROSES (*An Old Subscriber*).—We cannot undertake to name florists' flowers. They are too numerous, and so many are nearly alike.

SEEDLING PELARGONIUMS, &c. (*N.*).—Not so good as many others of the same colour. The Rose appears worth keeping for garden decoration, but the specimen sent would not satisfy a florist.

PELARGONIUM (*J. Tomkins*).—We cannot undertake to name florists' flowers.

INSECTS (*R. F. M.*).—*Notonecta glauca*. This water bug (misnamed novocata, and spoken of as a beetle), feeds upon other water insects. It is common in every piece of standing water. (*M. A. M.*)—The small snails sent are half-grown specimens of *Zonitis pellicida*, a small British species. They and all snails are especially fond of brewers' grains, which they will eat in preference to your Orchids. The grubs are the larva of the pretty Asparagus beetle, *Crioceris Asparagi*. Hand-picking is the only really effective remedy. (*C. B.*)—We still believe the curling of your Rose leaves to have been caused by mildew or other atmospheric cause, which brought them into a state especially agreeable to some of the many species of small caterpillars which feed on the leaves. Yours were so dried up as not to allow of investigation.—W.

NAMES OF PLANTS (*Julia*).—*Astilbe rivularis*. (*Yorkshire*).—Yellow. *Cotula*, sp. Red. *Gaultheria reticulata*. (*E. M. R.*).—1, *Erica splendens*; 2 and 3, *E. jasminiflora*; 4, *E. decora*. (*H.*).—1, *Nepeta Massinii*; 2, *Escallonia rubra*. (*Wexford Subscriber*).—*Asplenium macrosporum*. (*G. A. S.*).—1, *Davallia lineata*; 2, *Oncoclea sensibilis*; 3, *Nephrodium flaccidum*; 5, *Adiantum cuneatum*. (*Young Gardener*).—1, *Philadelphium tomentosum*; 2, *Tenacium fruticosum*; 3, *Corydalis lutea*. (*H. L.*).—1, *Trifolium procumbens*; 2, *Euphorbia helioscopia*; 3, *Veronica agrestis*; 4, *V. variegata*; 5, *V. scryphifolia*; 6, *V. Buxbaumii*. (*J. G. L.*).—*Pajanelia Rheedii* (large); *Coltena frutescens* (small). (*G. M. C. W.*).—1, *Scaevola crassifolia*; 3, *Zenobia speciosa*; 4, *Spiraea Douglasii*; 5, *Ribes speciosa*; 6, *Spiraea arifolia*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending June 23rd.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE

CRÈVE-CŒURS.

So many questions come to us about the French fowls, that we do as we did some years since—we print the description of

them as given by M. Jacque, who is equally gifted with pen and pencil. His drawings are certainly the best we ever saw of fowls. They represent the bird fairly, without exaggeration or mannerism. Each one has its separate points well defined. The Spanish has nothing of the Cochins, and the Poland nothing of the Dorking. But the truth never pleases. He says the

one hook on poultry got him into more hot water than every other act of his life. Half the poultry-keepers in France fell foul of him. He said too much for one breed, not enough of another. He was overwhelmed with unprofitable correspondence, pulled down his houses, sold his stock, and turned to other pursuits; nevertheless, he remains the greatest authority we have on these breeds.

We will now give the principal points he describes as belonging to the *Crève-Cœur*.

Ample body, square-built, wide, standing well on substantial legs; back almost horizontal, falling slightly towards the tail; breast, thighs, and wings well developed; limbs short; very large head; top-knot, whiskers, and beard; double comb in the shape of horns; wattle long and pendant; deaf ear small and hidden; four-toed; breast and belly feathers long and plentiful; flight feathers of the usual length; sickles and tail coverts very long; in excellent specimens plumage quite black, in ordinary ones yellow and whitish. Gait proud and serious.

An adult should weigh from 7 to 8 lbs. The flesh should be very abundant, bones weighing only one-eighth of the whole. Top-knot, ample, voluminous, heavy. The pointed feathers should fall all round the head in good specimens: the middle feathers should stand upright, and some should fall in front. Whiskers very full.

Beard long, voluminous, and falling below the wattles.

Comb variable, but always forming two horns; new parallel, upright, and fleshy; now joined at their base, slightly uneven, pointed and dividing at their summit, but always having some interior ramifications like the horns of a young stag.

Deaf ear whitish, of ordinary size, nearly hidden by the feathers of the whiskers and top-knot.

Wattles long, fleshy, and pendant. Nostrils open, large, and prominent.

Physiognomy of the head.—The eyes nearly disappear beneath the feathers of the top-knot. The comb, taking the form of horns, gives to the face of a *Crève-Cœur* the appearance of a satyr.

Colour of the leg black, or deep slate blue.

The plumage should be entirely black, relieved by metallic reflections, blue or greenish about the neck, on the hackle, wings, tail coverts, and large and small sickles. The rest is dead black save the feathers of the abdomen, which are of a brownish black. The top-knot generally becomes whitish at the back after the second or third moult.

Many specimens have the hackle, saddle, and tail coverts straw-coloured. They are pure, and breed pure birds, but they are less esteemed by judges.

Such is the description of the cock. The full-grown hen should weigh 6 lbs., should have a large head, and full top-knot. The latter differs somewhat. In some cases the feathers are short, leaving the eyes uncovered. In others the feathers are so abundant that the head is hidden in them, and the bird can only see things that are on the ground. Beard long, pendant, and strong, larger at bottom than at top; gills very small; deaf ear small and whitish, hidden in the top-knot and the whiskers.

The top-knot, which is black at first, becomes whiter and whiter each time after moulting.

GAME FOWLS IN FORMER YEARS.—No. 2.

THE most celebrated cock-fighting feeders of the last generation, before the sport was abolished by law, were Gilliver, of Colleshill; Potter, the late Earl of Derby's man, Gilliver's principal opponent; the two Nashes, Walters, Leicester, Neale, Tom Spring, Peter Crawley, Harry Gomm, Frank Redmond, Mountain, and others, chiefly provincial men. Gilliver was the most successful of them all, bought a house out of his earnings, and died in 1832, leaving a son, or nephew, who lives at Polesworth, North Warwickshire. Gilliver, senior, was a really good and well-known authority on all matters connected with Game fowls, though he fought far better birds, it is said, than he ever bred himself, and so was a better fighter and feeder than a breeder. Gilliver won seven of the largest and best-fought mains in England. Colleshill (1), Lichfield (2), Chester (3), Newton, Lancashire (4), Oxford (5), Manchester (6), and Preston, Lancashire (7). The one fought at Manchester was his best-fought main and was only just won. He was once well beaten at Manchester by the celebrated Manchester Brown Reds, and the Dark Greys and Cheshire Piles (white legs).

Gilliver won principally with the Brown Reds, and he classed

the best breeds of Game fowls in his district, the midland counties, as follows:—For the pit—1st, Brown Reds, brown breasts, greatest winners; 2nd, Dark Greys, hardest, least beaten of any—these two breeds the best birds; 3rd, Piles, red eyes, white legs, quite as sharp; 4th, Black-breasted Reds, white legs, less sharp; 5th, Duckwings, red eyes, willow legs, not quite so good. Black-breasted Reds (willow legs), Blacks, and most other colours he classed as inferior birds.

A Cheshire correspondent sent me the following list, classed in quality for the pit, at the present time in his district in Cheshire, the first named not common:—1st, Birchen Duns and Reds, quickest (dun breasts, however, are softer), provincial; 2nd, Brown Reds, most used for the pit; 3rd, Dark Greys, not common; 4th, Blood Piles, red eyes, yellow legs; 5th, Black-breasted Reds, dark birds, willow legs. Duckwings inferior there, and white-legged birds scarce, as are Whites. He says Game cocks run 6½ lbs. there as an average, which, I think, is heavy. This is a much higher weight than the old Cheshire white-legged or other Cheshire breeds used to average.

In London these three sorts were chiefly used for the pit:—1st, Brown Reds, most common and most used; 2nd, Dark Greys, hardest and best birds of all; 3rd, Black-breasted Reds, red eyes, white legs, with the wheaten hens. These last not quite so good.

In my own district in the country the strains stand as follows, as good winners in the pit at present:—1st, Red-breasted Ginger Reds, bright red eyes, yellow legs; cocks bright red, hens light ginger partridge colour, a peculiar provincial strain, bred in East Suffolk, and formerly at Newmarket, Cambridgeshire side. These have not been beaten for thirty-five years, and are very fast. 2nd, Dark Greys, grey breasts, the hardest birds of all; 3rd, Brown Reds, red-brown breasts, the most fought of all; 4th, Bright Red Blood Piles, marble-breasted cocks (bred from Ginger Red hens originally), with white legs and bright red eyes (the old Cheshire Piles).

Of these, Ginger Reds and Piles are quickest, and Dark Greys and Brown Reds the hardest. We have also two strains of Black-breasted Reds with willow legs and red eyes, with very red cocks, that beat the Brown Reds. The hens of one strain are wheaten, and in the other Partridge-coloured. Both are originally from Newmarket, and are, I think, the best in England.

I hear that yellow and willow-legged Piles are now preferred in some places to the white-legged. I prefer the white-legged as gamier birds myself. I also hear that English Game fowls are now fought in France, the French breeders near Paris buying them up through their agents in London, especially about Hanworth, Hounslow, and Hampton Court. I have been informed that the English jockeys at Paris have brought this about.

I have quoted a little though not much, from "British Sports," by Capt. Delamere Blaine, as to the Duke of Leeds's breed, and some of the titled breeders and the feeders' names. The characteristics of the fighting qualities, and the notes on Gilliver, are copied chiefly from the old sporting records in London and Newmarket, and will, therefore, be found to be quite correct. I have, however, chiefly quoted from my own notes and experience.—NEWMARKET.

PACKING EGGS.

HAVING read in your paper the letters of "CONSTANT READER" and Mr. Cooper, I can fully verify their statements as to the safety of packing eggs in sawdust; at the same time I wish to mention that the eggs when boiled taste of the sawdust. I now use bran.—J. G. I.

PRIZES FOR BRAHMA POOTRAS.

AT this season the committees of some of our leading winter poultry shows are revising their schedules to meet the growing claims of the more popular breeds. Permit me, very briefly, to remind secretaries and committees of the strong and general expression of public opinion which was manifested during the winter months by a great number of letters in your columns and elsewhere in favour of liberal and equal prizes to both Light and Dark Brahmas. These letters came from various sources, from breeders of one and of both varieties, from secretaries of shows, from those who were impartial and who kept no Brahmas at all. Differing as they did in their origin, they were heartily unanimous in their demand that the growing popularity of the Light birds should be recognised by their

being placed on a perfect equality, both as to cups and prizes, with the Dark Brahmas.

Managers of shows are usually observant of and anxious to meet the wants of the public. They may rest well assured of two simple facts—first, that no classes are more popular than those for Brahmas; secondly, that where equal prizes are offered to each variety there will be an equal if not a larger entry of light Brahmas. At Winchester the number of entries was, Dark, ten; Light, twelve!—OBSERVER.

CHICKENHOOD.

"EARLY chickens, or, indeed, chickens at any period of the year, are all very well for those who can have them, and for those who have patience to see after them," said a farmer's wife; "but patience is a rare thing now-a-days, not one girl in ten will take the trouble, 'bother' she calls it, to see to them. Why only last February I had eight Brahmas hatched as fine and strong and likely to live as any May birds; what does the housemaid do but stir up the kitchen fire in a temper. They none of them like birds, no, not one of them. I half fancy we should not, if we were in their place. Well, the chickens were never seen after that vigorous poke of the fire. Hot cinders tumbled out in profusion, fell into the basket, burned up blanket, and birds, and everything—nothing but a few charred embers could be found on the hearth."

Most people complain of failure in the rearing of chickens, and no wonder; very few know how to do it successfully, even of those who have tried for years. There are so many things to consider, so many chapters of accidents to pass through, and then the chickens are usually left to the care of men or boys, and the latter are no more fitted for the task than they would be to polish Dresden china. Then some owners of poultry do not let those in charge have the least chance of success. I am not speaking of the hatching of expensive eggs, or the rearing of chickens for show purposes—these are often overcared for, but of such as are kept in country homes for household use—reared, in fact, as an article of food.

Now, there is Squire Bentley; he delights in eggs and chickens, would have fresh-laid eggs on his breakfast table every day in the year, and chickens never come amiss to him, however dished up. He is quite sure his poultryman fails far oftener than he succeeds; they have few eggs, and half the birds hatched never attain any size. A few years ago he made considerable alterations in his grounds near the poultry-yard, and raised the adjoining road a foot higher than the yard, so that all the surface rain water from a large garden drained into it, consequently keeping the soil cold and damp, even when it had the appearance of being dry. No amount of generous feeding could overcome this evil, or in the matter of success, compete with indifferent food on a dry warm soil; and "yet," said the man, "master never thinks that a poor hen must provide herself with flesh and feathers, before she can think of eggs, or anything else. The poultry would soon pay the expense of raising the yard a few inches higher than the surrounding ground." But this Squire Bentley does not understand; it is an economy of Nature he has never studied, and, therefore, would not believe, and he looks upon the matter of raising the yard as so much useless trouble and expense.

There is also Mrs. Martin; she keeps poultry, not for the love of it, but from necessity, for living far away in the country she could not otherwise easily provide her household with eggs and chickens. The fowls are there as it were only on sufferance, for she does not wish them to be seen or heard. If there had been a kind of fowls, doing their work in silence, pullets that laid eggs in plenty, without rejoicingly proclaiming the news to equally noisy partners, they would have been the very sort for Mrs. Martin. As it is she has removed them as far as possible from her abode. Their roosting place is everything that can be desired, their run a fine large one covered over with wire, so that the smartest Hamburgh could not possibly escape; they are well fed, and have green food in abundance, yet they do not succeed. The chicks die off in numbers before they are a month old, and the henwife says she "cannot think how it is, for they have everything heart could desire." Two long rows of elm and beech trees interlace their branches over this poultry-yard, and make almost perpetual shade, so much so, that the fowls try in vain to catch a glimpse of the summer sunshine, so spend their days fretting when they should be nursing chickens.

Then there is Mrs. Thornton; she often loses her chickens not from the want of sunshine, or from the effects of a damp

soil, but from an injudicious mode of feeding. She is quite sure the little things can want for nothing when they roam at large with their mother, and feels no apprehension when the sloppy bread and water is eaten up but slowly, or when the meal stirred up with cold water settles down to the dish bottom, and after standing days must be thrown away. To scald their meal with milk, or to boil young chickens a few eggs now and then, just to carry them safely through a cold time, when some bitter east wind is turning the green grass brown, such would be an extravagance Mrs. Thornton would not submit to. So her birds fail, they have not strength to face adverse winds. They might live on through some summer of exceptional mildness; but chickenhood in England must encounter various gradations of warmth and cold, of damp and dryness, all extremes of which are injurious to them.

Now, there are some things, and they are very simple and inexpensive, perfectly indispensable in the successful rearing of chickens. They should have a good shelter from wind and rain, a run over fresh clean grass, and be kept close to the person who feeds and cares for them, and one person and one only should be responsible; divide the responsibility and you increase the chance of loss. They should be near so that they may be frequently fed, and the food should be taken away when they have eaten their fill, not left to be trodden into the grass or gravel, or stolen by birds. Now, if the chickens are reared a long way from the house, they will often be forgotten, will have to wait for their dinner until some storm is over, or it may be go supperless to bed. To leave food standing might seem to avoid this evil, but then it is wasteful to do so; it encourages a false appetite, a constant craving after dainties. The hen and her chickens should have a run to themselves, there should be no intruders, not even another hen with chickens, for the day of battle would come, and though the mothers might not harm each other, the chickens would suffer. Nor is it well to coop two hens near each other, and let the young ones wander abroad, for they might not always return to their own mother; then a skirmish would ensue, and the poor little birds would be terrified. Two hens with broods of about the same age were from necessity during a wet season sheltered in an old barn, the hens were confined to their coops, but the chickens were free to roam over the place; they were so nearly the size and colour of each other, that no evil result was anticipated. All went well for a time, then it was found that one mother had stolen all the chicks, wiled them away from their own mother. They were taken back to her, put under her wings in the dark—to no purpose they rushed back to their self-adopted mother on the first opportunity, and she, proud of her large family, stretched out her wings wide as they would spread, and yet vainly strove to cover four and twenty chickens, while the poor forsaken mother after grieving for a time made the best of her circumstances by beginning life anew.

It is also an unwise, yet a very common practice, to give a hen more eggs than she can well cover. It is a kind of greed very pleasant to indulge in, for most poultry-keepers are apt to count their chickens before they are hatched, yet the after-counting would average more if one less than the bird could easily cover, rather than more, were given to her. Many people fancy if the eggs are under the hen's wings they must do, forgetting that the hen can only spare a certain portion of heat, however fat and well feathered she may be, and it is possible to spread out that heat until its effective power is lost. If you wish your chickens to have their mother's care and shelter for some time, as in the case of Black Spanish, and the hen cannot stay too long with them, do not allow her to indulge too much in the chickens' food, for chopped eggs and such dainties are not necessary for her health, and would only put her into good condition too soon, and then she would find out that it was much pleasanter to have little chicks than big ones, and so think she would seek a new nest, and leave the old birds to do as they could.

Now, this pitiful time comes to all chickens when the old mother turns them adrift—a sad time it is for them, however big and strong they may have grown. She no longer answers their eager call, or warns them of coming danger, or catches flies for them, or waits aside from the food until their hunger is appeased. No, the flies and dainty bits are all for herself now. She does not appear to care in the least for her orphaned little ones, leaves them for the society of others like herself, and quietly trims out her disordered feathers on some sunny slope, suddenly grown deaf to their troubles. If she be an easy-tempered hen, she just leaves them alone, takes no

notice of them, or it may be for a time permits them to follow her, even to nestle close up to her at night; but then it is for her own sake, she likes their warmth. But the chances are that her leave-taking is once and for ever, and comes to them without any softening gradations. Then the poor birds wander up and down, making a piteous wail. Sometimes they stray far from their accustomed walks, and must be sought for, or they rush about after every upgrown hen, thinking they have found their lost mother, only to be sent away with little pecks and snaps, and angry tones. At this period of their lives they often meet with an untimely end; every stray chicken, notwithstanding the proverb, does not come home at night to roost.

In the warm summer evenings a leafy tree has more charms for them than the pent-up hen house. In such a position they are not safe from cats, to say nothing of storms that may suddenly come down upon them. At such times if they are considered of any value, they must be well looked after, counted up morning, noon, and night, and the person who feeds them will ever have most influence over them. Chickens may be so taught that they will obey the first sound of the voice, and come from a long distance in answer to it; but then to insure this, they must not be deceived—only called for when they are wanted to feed; and if this be done regularly, they quickly learn to seek their homes, not only for food, but for protection from dangers which they are not strong enough to battle with. This great change in their lives once safely over, they take upon themselves as it were an individual independent action, rely upon themselves, and grow up fast, and well repay the care and trouble bestowed upon them during the days of their chickenhood.—*MAUD.*

THORNE POULTRY SHOW.

THE arrangements of the Committee for this Show, held on the 17th inst., were admirable, and the generality of the specimens exhibited were such as are rarely met with. By the kind permission of Makin Durham, Esq., there was fully double the extent of show-ground as compared with that afforded on previous occasions, and the pens throughout being in single tier, the Exhibition was seen to great advantage. The weather being exceedingly clear and sultry, the birds appeared to suffer much from the continuous sunshine, and we noticed many exhibitors busily engaged fastening pieces of newspaper, and even pocket-handkerchiefs, to shade their particular pens; for the poultry, more especially about the middle of the day, panted from sheer exhaustion. This is a disadvantage that will ever attend out-of-door exhibitions where no shelter is provided, but constant heavy rains bring far more inconvenience; therefore, we can heartily congratulate the Managers on the favourable weather they this year enjoyed. The grounds, which have recently been laid out with great care and good taste, were thronged with a highly respectable company almost from the very hour of opening to the time of closing, and we understand that great promptitude was evinced in repacking the birds.

The competition in most of the classes would bear comparison with the largest of our poultry exhibitions, and though in a few instances mounting was rapidly progressing, the generality of even the Game fowls proved to be in excellent hard feather and condition. The classes devoted to birds of the current year were well filled, and with specimens very nearly at maturity, consequently this portion of the Show proved most attractive. The sales effected through the number of pens "claimed," was considerably in advance of former years, and in the "Selling classes" great numbers changed hands.

SPANISH.—First, H. Beldon, Bingley. Second, J. Thresh, Bradford. Highly Commended, Messrs. Burch & Boulter, Sheffield. Commended, Messrs. T. C. & E. Newbitt, Epworth; E. Brown, Sheffield.

COCHIN-CHINA.—First, C. W. Brierley, Middleton. Second, T. Stretch, Ormskirk. Highly Commended, C. W. Brierley; W. A. Taylor, Manchester; W. Harvey, Sheffield.

BRAHMA POOTRA.—First, E. Leech, Rochdale. Second, F. E. Hoyle, Hooton Levett. Commended, Lady Hawke, Womersley.

DORKING.—First, H. Pickles, jun., Skipton. Second, J. Elgar, Newark. Highly Commended, W. H. King, Rochdale; H. Beldon.

GAME (White and Piles).—First, J. W. Thompson, Southwam. Second, Messrs. G. & C. Furness, Acerington. Highly Commended, Messrs. Sales & Bentley, Crowle.

GAME (Black-breasted and other Reds).—First, C. W. Brierley. Second, Messrs. Sales & Bentley. Commended, B. Jarvis, Mansfield.

GAME (Duckwings, and other Greys and Blues).—First, J. Mason, Worcester. Second, E. Aylroyd, Bradford.

GAME (Any breed).—First and Cup, E. Aylroyd. Second and Third, J. Fletcher, Stoneclough. Highly Commended, H. M. Julian, Hull.

GAME COCK (Any breed).—First and Cup, C. Challenger, Steeley. Second, H. M. Julian. Third, W. H. Wheeler, Carlton.

BARBS.—First and Second, E. Horner. Highly Commended, A. Dove, York; E. Brown, Sheffield.

SELLING CLASS.—First, J. Hawley. Second, J. Deakin, Sheffield. Highly Commended, C. Gravel, jun., Thorne; Messrs. T. C. & E. Newbitt; E. Horner. Commended, G. Kenyon, jun., Thorne; T. Balderstein, Derby; T. Stather; E. Horner.

RABBITS.

LOP-EARED (Buck and Doe).—First, A. H. Easton, Hull. Second, C. Gravel, Thorne.

LOP-EARED (Buck).—First, A. H. Easton. Second, H. Yardley, Birmingham. Highly Commended, C. Gravel.

LOP-EARED (Doe).—First, G. Jones, Birmingham. Second, C. Gravel. Highly Commended, A. H. Easton. Commended, W. Grant, Doncaster.

HEAVIEST.—First, J. Taylor, Sheffield. Second, A. H. Easton. Highly Commended, H. Gravel. Commended, G. Jones.

EXTRA CLASS.—First, J. A. Rowland, Doncaster (Himalayan). Second, A. H. Easton (Silver-Grey). Highly Commended and Commended, C. Gravel.

The longest ears were 2½ inches, and the widest, 5 inches, easy measurement; and the heaviest Rabbit, 13½ lbs.

The Judges were Mr. Edward Hewitt, of Sparkbrook, Birmingham; and Mr. E. Hutton, of Pudsey, near Leeds.

GLASGOW AGRICULTURAL SOCIETY'S SHOW.

THIS Society held its fourteenth annual Show on the 10th of June, in the Cattle Market. The Exhibition was well patronised, the weather being fine.

The show of poultry was very small. The Society making it a rule that persons wishing to exhibit must pay a subscription of 10s., and an annual subscription of 5s. before being allowed to exhibit any kind of stock, there is no inducement to send birds for competition where a first prize is 20s., and for Bantams 10s. It is a great mistake to require exhibitors of fowls to pay the same entry money as those who enter cattle or horses, the prizes for the latter being from £3 to £6. This drawback must prevent many exhibitors who would willingly send birds from taking any interest in the Show, and deprive visitors of the pleasure of witnessing a good competition. Besides the sum mentioned, exhibitors are required to pay 5 per cent. on prize money, and provide pens for their own birds. It is to be hoped that more satisfactory arrangements will be made by next season.

Dorkings were not extraordinary. Cochins were very good. Hamburgs and Scotch Greys were fair. The first and second pens of

Game were good. *Bantams* were very middling, one of the hens in the first-prize pen (Black Red Game), having white earlobes. *Ducks* were very good.

The following is the prize list:—

DORKING.—First, H. Heys, Barrhead. Second, J. Logan, Eastshield, Carnwath. Third, Miss E. Oswald, St. Quivox, by Ayr.

COCHIN-CHINA.—First and Third, J. Stuart, Thistlebank, Helensburgh. Second, Miss E. Oswald.

HAMBURGH (Golden).—First, W. Thomson, Glasgow. Second, J. Logan. Third, R. Wilson, Forchouse, Kilbarchan.

HAMBURGH (Silver).—First and Second, J. Logan. Third, J. H. McNab, South Arthurrie, Barrhead.

SPANISH.—First, J. Logan. Second, M. Henderson, Ardrossan. Third, J. H. McNab.

SCOTCH GREY.—First, R. Wilson. Second, H. Heys. Third, J. Logan.

GAME.—First, H. Heys. Second, D. Gellatly, Meigle. Third, J. Logan.

BANTAM.—First, Miss E. Oswald. Second, R. Wilson. Third, D. Gellatly.

ANY OTHER BREED.—First and Second, J. Logan. Third, J. H. McNab.

DUCKS (White Aylesbury).—First, J. Dryburgh, Arkleston, Paisley. Second, H. Heys. Third, A. Bulloch, Milliken, East Kilpatrick.

DUCKS (Rouen).—First, J. H. McNab. Second, R. Wilson. Third, J. Logan.

ANY OTHER VARIETY.—First, Second, and Third, J. Logan.

GESE.—Prize, H. Heys.

HATCHING RESULTS.

Seeing that you have details of hen and chicken progress, I offer my mite of information in the same department, believing you will not receive a more successful report during the year. My nine hens and one cock are Cochins and Dorkings.

Sitting.	Date.	No. of Eggs.	Chickens.
1	January 8.	11	3
2	January 24	13	5
3	February 4	11	6
4	February 13.	11	10
5	March 17	13	12

11	May 15	13	11
12	May 17	13	11

One Dorking hen has not yet sat at all. I have no grass run for them, but a cribbed and narrow space for hens and chickens; and added to the above, I have had 582 eggs laid.—*ADELE DE SÉNANGES, Tunbridge Wells.*

ENTRY FEES AND PRIZES FOR PIGEONS AT POULTRY SHOWS.

AFTER carefully analysing the results of several poultry shows held last year, and examining prize lists of forthcoming shows, I am confirmed in the opinion I have held for some time—that exhibitors of Pigeons have not justice done them at the generality of poultry shows. I took up four catalogues, one each from the north and west of England, and two from the east. In three of them the Pigeon exhibitors paid for entry fees the amount given in prizes within a fraction, and in the fourth the fees exceeded the value of the prizes; and yet at the same shows the amount given in prizes for poultry exceeded the entry fees in one case by £10, another by £60, and in one by nearly £100.

The charges for Pigeon pens are not proportionate to the prizes when compared with those for the poultry. I have before me a prize list of a forthcoming show where the entry fees for a single pen of poultry will be 10s., but that pen has the chance of winning a cup value £5 5s; whereas for a single pen of Pigeons the fees are 8s., and the highest prize to be gained by that pen is £1.

I think, as a rule, committees copy prize lists without giving themselves the trouble to look at the matter, otherwise such charges would not be repeated time after time; for I am convinced that there are first-class business men on many committees who would without reference to any other list lay down a scale of fees and prizes on business principles that would be more equitable, and give greater satisfaction to all classes of exhibitors.—*L. WREN, Lowestoft.*

ARTIFICIAL SWARMING IN COMMON HIVES.

Would you be kind enough to inform me in what way I could make my bees swarm? I have sixty old stocks, and have had only four swarms out of the lot. Some have been hanging out at the mouth of the hive for a month. They are all very heavy, and I have no doubt that they are full of honey. I am

sorry to trouble you, but as I take a great interest in bees, I should feel obliged by a little information.—*J. M. E.*

[The best mode of making artificial swarms when common hives are used has been repeatedly described in our columns—first by Mr. Woodbury, in No. 161, then briefly recapitulated in reply to a correspondent in No. 271, and, lastly, detailed by "B. & W.," in page 179 of our present volume.]

THE GERMAN CENTRIFUGAL HONEY-EXTRACTING MACHINE.

THE external appearance of this apparatus is well represented in the engraving, which is taken from a machine which was made to my order in Germany, and which is fitted to accom-

modate four of my frames. It consists of an octagonal box made of inch wood 2 feet 3 inches in diameter outside, by 12 inches deep, which rests on a square platform with oaken cross-pieces underneath at each end to prevent warping, and cut thicker at the back than in front, so as to give the whole a slight inclination forwards. The cover is also formed of inch wood, and is moveable, being merely fitted on without being fastened in any way, whilst the front part is hinged so as to be readily lifted for the purpose of inserting full combs and removing empty ones. The two uprights on either side are 20 inches high, and with the cross-bar at the top are made of 1½-inch wood 4 inches wide, the tops of the former being morticed through the ends of the latter, and secured by keys driven through the tenons. A 1½-inch hole in front, stopped by a turned wooden plug, affords the means of drawing off the honey after it has been extracted from the combs.

The internal apparatus which is represented in the annexed engraving, consists of a

The machine is used by standing four combs, from which

the cell covers have been previously sliced off, inside the gratings formed by the strained fishing-line; and then hitching the spliced eye of a stout cord on an iron pin near the top of the spindle, the latter is slowly turned round so as to wind the cord upon it. A fulcrum being then obtained by placing the left hand on the machine, the cross-handle attached to the other end of the cord is grasped in the right, and a vigorous pull sets the four combs spinning at such a rate that they are speedily half emptied of their liquid contents. When this is effected the combs are turned round, and another spin completes the job by emptying the cells on the other side.—A DEVONSHIRE BEE-KEEPER.

IMPROVED WAX-MELTING APPARATUS.

WILL you or any of your numerous subscribers kindly inform me the best way of making beeswax?—IGNORAMUS.

[I have recently had a wax-filtering pot made in tin, which has a moveable strainer somewhat more than half way up from the bottom. It is used by filling the lower part with combs, which are kept down by the strainer. Water being then poured in until the strainer is submerged an inch or two, the pot is placed on the fire and boiled for some time, when the wax rising to the top may be poured off in a tolerably pure state. I pour all the liquid contents of the pot into a large pan three parts full of cold water, in which the wax solidifies. All the refuse having been thrown away the wax is then collected, tied up in a bit of muslin, and placed on the top of the strainer. A small quantity only of water being put in the pot, the whole is again placed on the fire and boiled until the wax has melted through the muslin, when it may be poured into a mould, and the process is complete. I derived the idea of this apparatus from the description which Dr. Bevan gives of the one used by him, aided also by the inspection of one shown in the German department of the International Exhibition of 1862. I have, however, contrived some essential improvements, especially as regards the prevention of the combs burning and adhering to the bottom. This pot can be readily made by any ordinary workman; but as it is difficult to give precise directions for manufacturing it, I think of having a few made by my own tinman, and will forward one to any address on receipt of post-office order or stamps for 5s.—T. W. WOODBURY, Mount Radford, Exeter.]

RHUBARB WINE.

COULD you favour me with a receipt for rhubarb wine? Which is the better plan—to boil the rhubarb in the water, or to steep the cut rhubarb in the water for a certain time, and not boil? I have met with a failure in both ways.—ECONOMIST.

[The following produces the best wine, is the most successful receipt we know, and is an answer to your query.

Take of rhubarb stalks (unpeeled) 60 pounds.
 „ loaf-sugar „ 30 pounds.
 „ red argol (powdered) „ 4 ounces.
 „ water, a sufficient quantity.

The rhubarb stalks should be bruised one by one with the mallet against the side or bottom of the tub. Four or five gallons of cold water should then be poured upon them, in which they should be allowed to macerate for twelve or sixteen hours. The stalks should now be put into the press, and all their juice pressed out. This, with the liquor in which they were macerated, together with the sugar and the argol, should be mixed in the tub, and the quantity made up to ten and a half gallons by the addition of cold water. (It would save trouble in measuring, if a mark were previously placed in the tub to indicate when this quantity was contained in it.) This mixture is the artificial “must.” The tub should now be covered with a blanket, and placed in a temperature of from 55° to 60°. Here it may remain, being occasionally stirred, for two or three days, according to the symptoms of fermentation it may show; it should then be poured off, straining it through flannel into the cask, which should be filled to the bung-hole, and placed across the tub, in order that the scum and yeast which will be thrown off may be caught and removed. The superabundant must, which will be one and a half gallons, must be poured into the jar, in order that as the fermentation in the cask proceeds, and the liquor diminishes, there may be a supply in readiness to fill up the cask, which must always be kept full or nearly so. In about a fortnight

the bung may, most probably, be put loosely in, and in another week firmly fixed, and the cask placed in the cellar; but this of course depends upon the state of the wine. If the sweetness has disappeared, or nearly so,—or if, on the saccharometer being placed in it, the index marks a specific gravity of about 40,—the wine has fermented far enough for cellaring; if it has not reached this point, the wine should be well stirred, and the temperature kept up to promote further fermentation. In a month or six weeks after cellaring it may be fined and drawn off into a clean cask, or the same properly cleaned and, if necessary, sulphured to stop further fermentation, before the wine is returned. The cask may now be finally stopped close, and if an effervescent wine be desired, allowed to remain until March, when it should be bottled, the corks wired, and the bottles laid down. But if a still wine, like hock, be desired, no other year in the wood, or even more, will be advantageous.

The only difficulty about this process is to find out the precise period at which the fermentation has reached the desired point. The saccharometer will show this correctly. About 35, as marked on the scale of Thompson's saccharometer, would indicate proper attenuation for wine intended to be effervescent; if it is to be still and dry it may be lower—25 to 30. But the taste may be educated so as to form an approximation to truth. As long as sweetness exists to any extent the fermentation is incomplete, and after eating a small piece of crust most persons may readily detect the presence of too much sugar in the wine. In this case the wine should be shaken or stirred, that the wine may “feed,” as it is termed, on the lees; fining, on the contrary, will check fermentation; and when it has gone far enough, sulphurous acid gas stops it, as in the process of “sulphuring,” which may be readily done by burning a few sulphur matches within the bung-hole, the cask being inverted.

Fining is generally performed by means of isinglass previously dissolved, or partly so, in a little of the wine. About a drachm of isinglass so dissolved and poured into the bung-hole, the upper part of the wine being stirred at the same time, will probably be found sufficient.

Thompson's saccharometer is costly; but a simple glass one, quite sufficient for our purpose, may be procured for a few shillings. It is called Roberts' Saccharometer.

In using this saccharometer, two things are necessary to be observed:—1st. The temperature of the liquor to be examined must be 60°; and 2nd, the division on the scale must be multiplied by 5 to obtain the correct specific gravity. For instance, should the must raise the instrument to 24°, as marked on the scale, multiply 24 by 5, and you will prove the gravity to be 120; about the proper gravity of the must, before fermentation begins.

As a rule it may be observed, that the finer the sugar, the more alcohol is produced from it. It may be noted, that as the rhubarb juice will iron mould linen, care should be taken when the stalks are bruised.]

OUR LETTER BOX.

BLACK RED GAME BANTAMS' EARLOBES (T. D.).—The colour of the earlobes of Black Red Game Bantams is not essential, but we should prefer them red.

SILVER HAMBURGERS (J. W.).—The accidental loss of an eye is a mere disadvantage in competition; it is never a disqualification. We do not believe it is possible to tell the sex of the chicken from the shape of the egg. We do believe the earlier eggs produce more cocks than later ones. We should prefer the April to the July chickens.

BEE'S NOT SWARMING (A Beginner).—Swarming appears to be very capricious this season. Many issued early in our own neighbourhood, but we have ourselves ordered swarms from four different bee-keepers, and up to the present time have received but two from one of them. You may possibly by the time this appears have had a swarm; if not, it might, perhaps, be well to buy a stock or a swarm that has already been bived. In the latter case it will be better to wait until the weather become cooler before removing it. You will see that a corresponding states that he has had but four swarms from sixty stocks.

POULTRY MARKET.—JUNE 24.

The supply is better, and the trade improves. Hot weather always increases the demand for poultry. As it also spoils a large quantity, it tends to keep up the price.
